The report states that the company continues to make satisfactory progress. During the past year 32 new customers, and the equivalent of 2,340 8-C.P. additional lamps have been connected to the company's mains, making a total of 330 customers and 20,067 8-C.P. lamps connected at the present time. To meet these requirements 310 yards of additional mains have been laid, while the capacity in cables and transformers has also been correspondingly increased. An additional 150-kilowatt set of generating plant has also been ordered, but owing to the strike in the engineering trade, is not yet delivered. During the past year electric energy to the amount of 214,044 Board of Trade units has been supplied to customers, at a revenue, including meter rent, of £5,179 13s. 9d., as against 179,360 units and £4,383 5s. 11d. revenue for 1896. The company has made a profit on the year's working of £2,044 13s. 0½d., as against £1,617 8s. 8d. in 1896, adding the balance of £191 19s. 5d. carried from the previous year, there is, after paying income-tax £23 2s. 8d., bank interest £18 8s., and writing off the sum of £ 00, being the balance of the preliminary expenses account, and putting £250 to depreciation, a sum of £1,845 1s. 9½d. available for distribution. The directors recommend that this should be applied in paying a dividend of 5 per cent (less income-tax), which will absorb £1,656 10s., leaving a balance of £188 11s. 9½d. to be carried forward. It will be observed that, in addition to the £100 written off the preliminary expenses account (which is now extinguished), and the £250 put to depreciation account, a sum of £70 1s. 2d. has further been written off the office furniture and fittings upon removal of the offices, making a total of £420 1s. 2d. written off and put to depreciation during the year. Mr. J. W. Woodall, Mr. John Dale, and Mr. J. Bell Simpson retire by rotation, but are eligible and offer themselves for re-election as directors. The auditors, Messrs. Bradley, Davis & Co., chartered accountants, also offer themselves for re-election.

Tramways Union Company, Limited.

A general meeting of this company was held at Winchester House on Tuesday, Mr. E. M. Underdown, Q.C., presided. In moving the adoption of the report, he said the step they had taken in regard to one of their tramways was extremely important. It would be satisfactory to them to know that in all probability that portion of their system which was intended to be worked by electricity would be in full operation in June. If, as they had not the slightest doubt, the results of this mode of traction proved to be more efficient and profitable, the receipts, which would provide the means of covering the outlay they had incurred for this purpose, would come into account during the remaining half of the coming six months. There had been increases in their expenditure at both Bremen and Bucharest, and the expenditure had not been lessened by the fact that forage had ruled comparatively high in those cities. At Bremen they had practically relaid the system, and otherwise improved it, with results eminently satisfactory. During the current year they would reap the benefit of the improved earnings. The progress of the works at Madrid had been extremely rapid, and the appliances they were putting down there might be confidently said to be of the best and most modern kind. Their colleague, Mr. Concanon, had bestowed the greatest attention on this matter. Among other things he went to the United States, and had satisfied himself that in the arrangements they had made, they had got the very best materials and appliances that could be procured. They all knew the great profit which was obtained by overcoming the mechanical difficulties which arose in the earlier stages of the progress of electricity, and he believed they would be able to work the traffic in Madrid in a very profitable manner.

Mr. George Richardson seconded the motion, which was unanimously adopted, and a dividend was afterwards declared, making 5 per cent. for the year, tax free.

Eastern Telegraph Company, Limited.

An extraordinary general meeting of this company was held on Tuesday to consider a resolution to the effect that the regulations of the company be varied by adding the following articles of association, viz.: 85a—"Continuing directors may act notwithstanding any vacancy in their body." The object of the resolution being to provide against the inconvenience arising through the number of directors falling below the *minimum* allowed by the articles of association, and to enable them to carry on the business of the company, including, of course, the filling up of vacancies.

The resolution was adopted.

Stock Exchange Settlements.—The Stock Exchange Committee has (1) appointed special settling days as under:—Wednesday, February 23rd: Cape Electric Tramways, Limited—285,157 vendors' £1 shares, fully paid, Nos. 1 to 285,157; City of London Electric Lighting Company, Limited—Provisional certificates for a further issue of 10,000 ordinary shares of £10 each, £2 paid, Nos. 90,001 to 100,000; Electric Construction Company, Limited—Further issue of 8,657 7 per cent. cumulative preference shares of £2 each, fully paid, Nos. 16,344 to 25,000; Electrical Copper Company, Limited—150,000 6 per cent. cumulative preference shares of £1 each, fully paid, Nos. 1 to 150,000. And (2) ordered to be quoted in the Official List: Barcelona Tramways Company, Limited—Further issue of 5,072 ordinary shares, Nos. 14,929 to 20,000; City of London Electric Lighting Company, Limited—Provisional certificates for a further issue of 10,000 ordinary shares, £2 paid, No. 90,001 to 100,000.

Elmore's French Copper Company.—A circular has been issued to the first mortgage debenture holders of Elmore's French Patent Copper Depositing Company, Limited, which states that the directors have received a proposal, after several weeks' negotiations, for the purchase of the founders' shares of the Société Française d'Electro Metallurgie, which constitute practically the main asset of the company. The sale of these shares will enable the sum of 6s. in the £ to be paid to the first mortgage debenture holders in discharge of their debt. In accordance with the provision contained in the 10th condition endorsed on the said debentures, a meeting of the first mortgage debenture holders will be held at Winchester House on Wednesday, the 23rd inst., to consider the proposal.

The City of London Electric Lighting Company, Limited.—The directors have decided to recommend to the shareholders the payment of the following dividends, subject to the completion of the audit:—On the preference shares 6s. per share for the six months ended December 31st, 1897, making, with the interim dividend already paid, a total distribution of 6 per cent. for the year. On ordinary shares, Nos. 40,001 to 80,000, £1 per share for the year, and on ordinary shares, Nos. 80,001 to 90,000, 10s. 7d. per share for the year, being a distribution at the rate of 10 per cent. for the year ended December 31st, 1897. Both dividends will be payable on March 3rd, 1898.

Brush Electrical Engineering Company, Limited.—The directors have declared an interim dividend at the rate of 6 per cent. per annum on the preference shares for the half-year ended December 31st, 1897, payable on March 15th, 1898. The transfer books will be closed from March 2nd to the 16th, 1898, inclusive.

City of London Electric Lighting Company.—The transfer books and registers of members will be closed from the 16th inst. to March 2nd, both days inclusive.

TRAFFIC RECEIPTS.

The Bristol Tramways and Carriage Company, Limited. The receipts for the week ending February 11th, 1898, were £2,296 3s. 9d.; corresponding period, 1897, £2,120 15s. 5d.; increase, £175 8s. 4d.

The City and South London Railway Company. The receipts for the week ending February 13th, 1898, were £1,058; week ending February 14th, 1897, £1,062; decrease £4; total receipts for half-year, 1898, £7,514; corresponding period, 1897, £7,673; decrease, £159.

The Dover Corporation Electric Tramways. The receipts for the week ending February 5th, 1898, £101 0s. 5d.; total receipts, February 5th, 1898, £538 0s. 8d. The traffic returns for week ending February 12th, 1898, £105 8s. 6d.; total receipts, February 12th, 1898, £643 6s. 2d.

The Dublin Tramways Company. The receipts for week ending, February 11th, 1898, £375 9s. 5d.; corresponding week last year, £433 13s. 5d.; decrease, £58 4s.; passengers carried, 64,846; corresponding week last year, 68,108; aggregate to date, £2,478 5s. 8d.; aggregate to date last year, £2,463 9s.; increase to date, £14 16s. 8d.; mileage open, 8 miles.

The Liverpool Overhead Railway Company. The receipts for the week ending February 13th, 1898, amounted to £1,380; corresponding week last year, £1,219; increase, £161.

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending February 11th, 1898, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,146.

COMPARATIVE COST OF STEAM AND ELECTRIC POWER.

III.

The author is of opinion that electricity is finding it difficult to compete with steam power, or rather to effect a breach in the citadel, because nine-tenths of steam users do not allow a tithe of the constant charges to enter into their calculations of cost at all. They do not, therefore, suspect that their power is costing them so much as it is, and they also believe they are using more power than they really are—using, that is, in its true sense, not wasting it on shafting. It is in small steam plants that the very high ratio of constant charges is found worst developed.

Men who have any idea of what their power costs are very rare indeed. One man is quoted who did know that his 200-H.P. engine operated 6,160 hours a year, cost for everything but rent 2 cents an hour per horse-power on a basis of load factor being unity. But load factors are far from being unity; they are, as a rule, low, and the author tries to trace the line of demarcation on either side of which steam or electric power will be the cheaper to employ. Below 100 H.P. so-called constant loads will have a factor of only ·50 to ·75 on the brake H.P. of the engine.

Three sample cases are taken:—I. Unity load factors; II. High variable power load factors; III. Low variable power load factors. In the estimates the possible saving due to more direct application of power is not taken into account, although, undoubtedly, in cases of very low load factors there can be no doubt but that this is the most important consideration.

Indeed, in a case before us as we write, it happens frequently that the power absorption all the day may never exceed a seventh of a horse-power of current, and this would be running 4 to 5 hours of the day. With steam power, fuel alone would cost at least 2s. a day, and loss of time in the morning would run to an hour, and might affect two to ten men more or less directly. Attention to the boiler would cost either a man's whole wages or a large proportion of them, or it would delay work and call for partial attention of skilled men. Breakdowns and stoppages of small plant are innumerable and an expensive item additional to above costs. Our author estimates the cost of steam plant for an engine B.H.P. of 10, 25, 50 and 100 to be in round numbers £400, £800, £1,150 and £1,800. These are the laid down costs, including buildings, iron stack and all details of engines and boilers of good design. The annual costs per year for insurance, rent, depreciation and interest are respectively £88, £131, £189 and £285. The load factors are now assumed as follows:—Case I., 100 per cent.; Case II., 46 per cent., made up of five hours at 30 per cent., three hours at 50 per cent., and two hours at 80 per cent.; and Case III., load factor of 18 per cent., made up of four hours at 10 per cent., four hours at 15 per cent., and two hours at 40 per cent. As small plants are, as a rule, non-condensing this class of engine is assumed, and for Case I. the four engines will cost in labour as follows:—

The 10-H.P. engine 60 per cent. of a man's time, or £93; the 25-H.P. engine, man's full time or £156; the 50-H.P. engine, man's full time at £187; and for the 100-H.P. engine, full time of engineman and a fireman at £320. These are American figures, of course, the wages of engine and boiler men being rather high in America, on account of the necessary high wages due to cost of living, but the figures are given as for efficient men and are not a minimum. For Cases II. and III., without going into detail, the wages costs are for the four powers, £78, £117, £156, and £187; the cost of oil, waste, and tools being £7½, £15½, £26, and

£40. Allowing ash removal to equal 2½d. per ton of coal, coal to cost 8s. to 16s. per ton, and water about 8d. per 1,000 gallons, the cost of each case can be made up.

REVIEWS.

Lockwood's Builders' and Contractors' Price Book, 1898. London: Crosby, Lockwood & Son.

The new edition of this year book appears to be carefully edited and brought up to date. In the preface it is stated that in the building trade (especially in London) the past year has been an exceptionally busy one. As a consequence prices have gone up, so that the cost of building now is in excess of what it was a year ago. In the electric lighting section of the book reliable guidance is given, and reference made to latest developments. The free wiring system is spoken of, and the method of the Conduit and Insulation Company. The object chiefly aimed at in the information given, is to enable builders to form a correct idea of the probable cost of installing the electric light where current is supplied from a generating station. At the same time the uses are explained of the machinery and apparatus required in the case of private installations. A few names are given of makers of steam engines for driving dynamos, but the possibility of using gas engines for the purpose does not appear to be recognised. The "General Conditions" issued by the City of London Electric Lighting Company are given as illustrating the requirements usually imposed by supply companies.

The Automotor and Horseless Vehicle Pocket Book of Automotive Formulæ and Commercial Intelligence for 1898. London: F. King & Co., Limited, 62, St. Martin's Lane, W.C.

This pocket book has been compiled by Mr. G. H. Little, C.E., and contains a good deal of useful information, a great deal of it relating to the subject of automotors, but a good deal, shovelled in, doubtless, as a fill up, having not the remotest connection with the subject, such, for instance, as the Morse or telegraph alphabet, nautical speed tables, and a fire-stream (fire engine) table. However, in spite of absurdities of this nature, and they are very plentiful, there is very much that has a very direct bearing on the subject, such as "Tractive Data Relating to Cycles," "Ball Bearings," "Chain Gearing," "Liquid Fuel Burners," "The Serpollet Boiler." Doubtless in future editions the really useful matter will be extended and the useless omitted.

Practical Electricity and Magnetism. By John Henderson, B.Sc. (Edin.), A.I.E.E. London: Longmans, Green, and Co.

This volume is the second of a series of laboratory manuals by two authors, who jointly sign the preface to the series. Its 390 small pages, openly printed, and freely illustrated, traverse most of the ground of electrical measurement. Explanations of the principles involved are omitted, because, as explained in the preface, they would give the book "unwieldy dimensions; besides, mathematical investigations do not come within the scope of a practical manual, but of a theoretical treatise." The practice of electricity and magnetism, with which the work deals, is the practice of a science school, not of an engineer's laboratory.

The book is not of a kind which recommends itself to a reviewer. Errors of orthography, punctuation, and typography, a deplorable English style, loose and inaccurate statements meet him continually, and give a disagreeable impression of negligence and inexactness. Still, books are not made for reviewers, any more than examinees are made for examiners, and such expressions as "the annunciation," not of a virgin, but "of a law" (the law in question was not Newton's maiden effort), "staunous acid," "analine," do no one any particular harm, while not a few famous philosophers, and indeed journalists, have written infamous English prose. So a student whose general training is wide enough to supply the mathematical demonstrations necessary for the experiments, will probably not be misled by the loose and inaccurate statements of Ohm's law, page 24, or of the swing of a ballistic galvanometer, page 211, by the irregular use of H and H in places where both mean the same thing, or the reason for using a heterostatic method on page 238. Errors in the formulæ of page 195 are, however, more serious.

Apart from such criticism, which we are not disposed to press, the book presents a fairly extensive collection of such methods of electrical measurement as are commonly used in technical schools, and will be useful to many science teachers. The collections of references to recent English scientific papers at the ends of the several chapters is certainly a valuable feature.

THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.

The seventh annual meeting of the American Electro-therapeutic Association, an abstract of which has recently come to hand, was held at Harrisburg, Pa., in the Academy of Medicine, on September 21st, 22nd and 23rd, under the presidency of Dr. William T. Bishop, of Harrisburg, who called the meeting to order at 10 a.m. on Tuesday, September 21st. The Rev. Leroy F. Baker, of St. Paul's P.E. church, offered an opening prayer, after which Mayor Patterson welcomed the delegates to the city. Dr. Robert Newman, of New York, a former president, responded in a very witty strain, and took occasion to remark that electricity was not treated with the consideration it deserved in the medical colleges.

The privileges of the floor were extended to the many visiting physicians.

Dr. Margaret A. Cleaves, of New York, chairman of the committee on meters, presented her report. She drew attention to the fact that several makes of meter had been withdrawn permanently from the tests of the committee because of their demonstrated inefficiency, and that a new company had come into the field with a novel apparatus—a milliamperemeter and a voltmeter for use on alternating current circuits, both sinusoidal and the interrupted or faradic.

Dr. Robert Newman, of New York, read a paper on "Electric Treatment in Gout and Uric Acid Diathesis." From careful observation and experience, he could positively assert that gout and kindred diseases could be checked, relapses prevented, and in many cases a cure effected by the judicious application of electricity, particularly the static form. He cited himself as a case in point. The advantages of static electricity are that it is generally diffused through the body, penetrating deeply; it is a general tonic; the "breeze" generally allays the pain in a few minutes, and secures freedom of motion; headaches and mental confusion are dissipated, and the temperature and circulation equalised; the icy coldness of the feet relieved, nervous debility removed, the secretory and excretory organs stimulated, inflammatory products absorbed; it also gives passive exercise. Urinary analyses were presented, verifying the claim for static electricity to abate gout.

Dr. Francis B. Bishop, of Washington, D.C., presented a paper on "Chorea." It was reasonable to believe that an unstable condition of the higher nerve centres predisposed to the condition, and that a poison affecting these centres might produce in one person epilepsy, in another general neurasthenia, and in a third chorea. In his section of the country malaria was largely responsible for chorea. Treatment consisted in attention to the bowels and diet, securing proper rest, and the use of static electricity by means of the "static cage," which, while gently stimulating the periphery, soothed the general nervous system; at the same time the patient is made to inhale the ozone, thus supplying oxygen to the impoverished blood.

"Sources of Atmospheric Electricity," by Dr. R. J. Nunn, of Savannah, Ga. He considered the solar system a vast static induction machine; the atmosphere close to the earth's surface must revolve with the earth as the latter turns upon its axis, while the tendency of that portion of the atmosphere at a distance from the earth's attraction is to accumulate behind the earth. At some point the atmospheric inertia must neutralise the earth's attraction, and where this occurred there must be friction, which would necessarily cause electrical phenomena; other factors were of importance, such as variation in pressure, temperature, humidity.

"Some Thoughts and Considerations on X Ray Work," by Dr. Eugene R. Corson, of Savannah, Ga. The author thought that the experiments on polarisation and refraction had been conducted too close to the tube and that there might be a point at which they would come within the control of present methods. He thought that the X ray would prove even more valuable in dislocations than in fractures. He suggested that a careful outline tracing be made of the negative by transmitted light, all extraneous light being shut off. The eye could much more readily pick out the essential features in such a tracing than from the usual print or radiograph. Radiographs were shown, proving that the X ray penetrated a deposit of urate of soda much more readily than it did bone. Many useful suggestions were made.

"Some Considerations Relative to the Therapeutic Application of the Current," by Dr. George E. Bill, Harrisburg, Pa. The writer threw out many suggestions as to the best methods of applying electricity, especially as to polarity.

"The Early Electrolysis of Nævus," by Dr. Charles R. Dickson

Toronto, Canada. Two cases were cited in support of the contention that nævus should be operated upon as early as possible, that the operation was much simpler, less prolonged, and the chances of scarring much less than when the operation was deferred until later in life.

"Heart Failure in Cardiac Diseases due to Defective Circulation," by Dr. Eli H. Coover, Harrisburg, Pa. Many suggestions as to appropriate treatment were made.

"Expenditure of Electrical Energy," by Dr. Margaret A. Cleaves, New York. In order to have an intelligent conception of the force by means of which electricity is made available, or of the laws governing its action, it was necessary to use a voltmeter as well as a milleamperemeter. In the treatment of acute neuritis, or acute pelvic inflammation, the wise physician would employ the minimum rate of expenditure in volt-amperes; our purpose is to expend the energy in such a way as to exercise a directive influence upon the molecules and atoms, not to cause any disruptive action. In the treatment of a fibroid tumour on the other hand, greater pressure would be required in order to overcome the resistance of the denser structures in the conducting path; current density in its practical bearings was carefully gone into. Numerous tabulated clinical records were exhibited, containing the data mentioned in the paper.

"Molecular Effects of Electricity," by Prof. Dolbear, of Tuft's College, Boston. The laws governing molecular motion were discussed in a masterly manner, physical laws are immutable, and the effects produced by what we call electricity, are really due to heat.

"The New Electro-Mercuric Treatment of Cancer," by Dr. G. Betton Massey, Philadelphia, was a further elaboration of a paper presented to the American Medical Association in June, 1897. It was only applicable in cases where the general system had not yet been infected.

"Current Regulating Apparatus," by Mr. Edward Jewell, E.E., Chicago, described methods of controlling dynamo currents and adapting them to therapeutic work. Absolute protection could only be secured by using the "motor-dynamo," which was made by connecting together by an insulated coupling the shafts of two one-eighth horse-power shunt motors, the winding on one of them having been reversed.

"Report of the Committee on Electrodes," Dr. Charles R. Dickson, Toronto, chairman. A binding post was presented, devised by one of the members, which could be used for any existing tips. The metric system of measurement was again recommended. On motion of Dr. Robert Newman the report was accepted, and on motion of Dr. John Gerin the Association accepted the metric system for all measurements.

"Galvinism as an Aid in the Treatment of Goitre," by Dr. Caleb Brown, Sac City, Ia. His cases ranged from 12 to 56 years of age, 33 per cent. being "hard" (a preponderance of connective tissue), and 67 per cent. "soft" (a predominance of fluid in the follicles or vascular tissue), every case of the first was benefited, but none completely cured. By galvinism in fully 75 per cent. of recent cases of "soft" goitre, occurring mostly in young women, the gland returned almost, if not quite, to its normal size, and had remained so in 25 per cent. of the cases. Mild currents, frequently repeated, was his rule.

"Further Studies of the Manifestations of Uric Acid, and their Treatment, Electrically and Otherwise," by Dr. J. Griffith Davis, New York. Special emphasis was laid on the statement that uric acid and its salts are the result or product of nerve and muscle waste. Among cases cited was one of very severe puerpural eclampsia, followed by a most obstinate form of insomnia, which latter yielded finally most satisfactorily to general faradisation. Among methods of prevention of the retention in the system of uric acid, the bicycle was lauded as a means of obtaining exercise in the fresh air, it was advised that the body be clothed in wool. For acute manifestations the writer preferred medicine, but for the more chronic forms had found the galvanic and faradic currents very useful.

(To be continued.)

THE N.C.S. NEW PATTERN POTENTIOMETER.

In this potentiometer, which is shown in skeleton diagram by fig. 1 and in general view by fig. 2, all the contacts are made on to the terminals of definite resistances.

The working of the instrument is as follows:—A secondary battery is joined on to the two terminals, F, and sends a current through the two dials, C and D, in series and then through adjusting resistances, K and H. The C dial has 150 exactly equal coils in it, numbered from 0 to 150. The D dial has 100 equal coils in it, the whole dial being exactly equal to one coil in C. The dial, K, contains 19 equal small wire resistances, and H is a carbon resistance for fine adjustment of the current.

A standard cell of known E.M.F. is joined up to A+ and A−, and the switch, L, is put over to A.

Any convenient galvanometer, the most convenient form being a D'Arsonval, is joined up to the galvanometer terminals.

Say the voltage of the standard cell, at the temperature used, is 1·4412; the arm of the C dial is then set to 144, and that of the D dial to 12

The galvanometer key is then depressed on to its first stop (taking care that the catch is underneath so that it cannot go right down) and the outside resistance, K, is adjusted till—with the switch on one

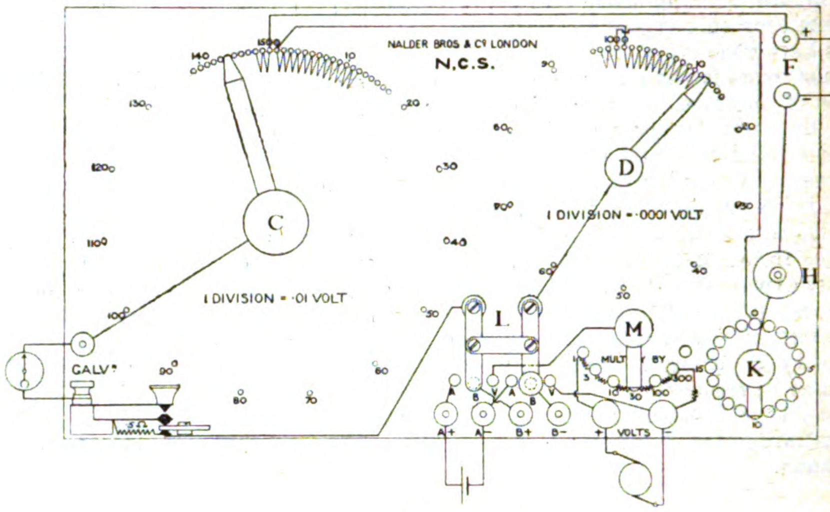

Fig. 1.

stop—the deflection is one way, and, with it on the next, in the opposite direction. The head, H, is then turned until an exact balance is obtained.

The catch on the galvanometer key is then turned aside and the latter depressed fully. This cuts out a ½ megohm which was previously in circuit to protect the cell.

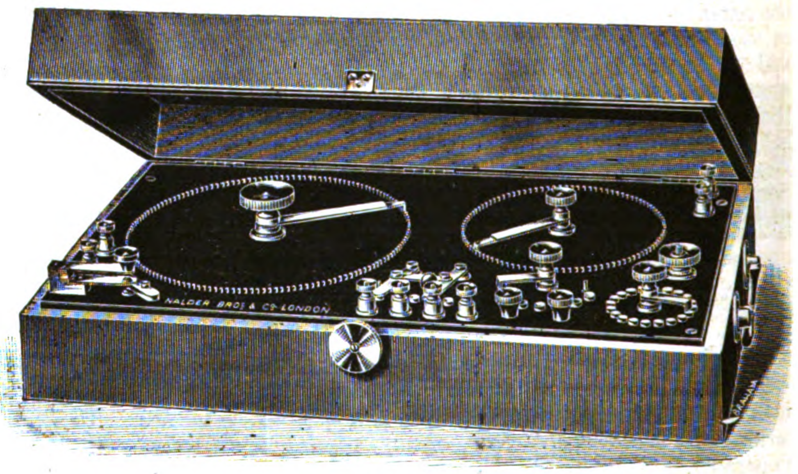

Fig. 2.

An exact balance can now be obtained by further adjustment of H or (if necessary) K.

The result of these adjustments is such that each division on C is now equal to ·01 of a volt, and each division on D is equal to ·0001 volt.

Any low E.M.F. to be measured is joined to B B terminals and the switch L set to B; for example, a Leclanché cell or the terminals of a low resistance for current measurement.

The galvanometer key is then again fully depressed and a balance obtained by moving C and D.

The E.M.F. between B and B is then read direct on the two dials; for example, if the reading on C is 83 and that on D is 67, the volts between B and B is ·8367. Any volts higher than 1·6 have to be measured on the terminals marked volts + and −, and with the switch, L, turned to V. The switch, M, is then turned to any convenient multiplying power, 3, 10, 30, &c., and the readings obtained from C and D (when the balance is obtained as before) has to be multiplied by this multiplying power; for example, if C is 103 and D 26, and M is standing at 30, the volts on the terminals are 1·0326 × 30 or say 30·98.

The resistances in H and K are arranged so that any voltage up to three volts can be used at F, thus allowing either a secondary cell or two large Leclanché to be used.

THE COST OF ELECTRIC ENERGY PRODUCTION.

In connection with the many references to this subject that we have recently made, and more particularly in regard to the supply of electric energy from lighting stations for tramway purposes (see the Electrical Review, January 14th last, page 36), some interesting figures and estimates have been sent to us by Mr. Shallcross, of the Birkenhead Electricity Works, to show that it is not only possible, but quite easy for such stations to profitably supply current at 1¼d. per unit for tramway work.

Our correspondent assumes station plant of an output equal to, say, 1,500 H.P.—which is quite a fair average for an ordinary large tramway system—and shows how, on the basis of long hours' consumption per day, an excellent profit can quite well be obtained, not merely at full load for the generating plant throughout the working day, but also when it is considerably underloaded.

Thus, a plant of the size mentioned, working for 18 hours per day—not an excessive daily period at all for tramways—would only be working at a little less than half load if it produced 2,000,000 units per annum.

The cost of this output our correspondent sets forth as follows:—

	£
Coal (10s. per ton)	1,859
Oil	100
Water	293
Wages, &c.	910
Repairs and maintenance	1,250
Interest and sinking fund	1,500
Insurance and sundries	200
	£6,114

and the revenue at 1¼d. per unit metered, *i.e.*, allowing for losses in mains, &c., amounts to £10,416, leaving a balance of profit equal to £4,302.

When the generating plant is worked at full load for the whole 18 hours daily, as might readily be done through the use of storage batteries in the main or sub-stations, the proportion of profit becomes still greater, and our correspondent's figures then may be set out as follows:—

Total output, 5,584,500 units per annum. Cost:—

	£
Water	864
Coal	5,499
Oil	100
Wages	1,066
Repairs and maintenance	1,250
Interest and sinking fund	1,500
Insurance and sundries	200
	£10,480

and the revenue at 1¼d. per unit, allowing for losses, &c., as before, amounts to £24,723, leaving a balance of profit equal to £14,243.

Without pledging ourselves in any way to the exact accuracy or completeness of our correspondent's figures, we may at any rate emphasise them as showing how important it is for municipalities and others, who are thinking of supplying current for tramway purposes, to bear in mind the long hours of supply, and the great difference which this makes in the net profits. The second instance which he gives would appear to show that energy might be generated by the tramway undertaking itself at a cost of ½d. per unit. It is hardly fair, therefore, to expect so much higher a price for current from a municipal station than what it would cost when generated by the tramway company.

THE DIRECT TRANSFORMATION OF HEAT INTO MECHANICAL WORK BY THE EMPLOYMENT OF ALLOYS OF FERRO-NICKEL.

By MARCEL DEPREZ.

In a recent article* I showed how the magnetic properties of the alloys of iron and nickel can be utilised for producing an electromotive force, undulatory in form, and I said that I would indicate the conditions under which these properties would be capable of giving practical results. A deep study of the question has led me to the conclusion that if these results are ever obtained great difficulties will have to be overcome, the nature of which will be explained in this article. Instead of the problem we had in view we propose to turn to account the thermo-magnetic properties of the same alloys to obtain an available mechanical work.

I.

We will suppose that in a uniform and permanent magnetic field has been placed a rod of ferro-nickel, moving round an axle passing through its centre perpendicularly to it, and also to the lines of force of the field. Left to itself, the rod will immediately place itself in the direction of the lines of force, and if we displace it, it will tend to return, developing a couple the value of which is given by the equation:

$$c = \mathfrak{M}\, h \sin \theta$$

in which $\mathfrak{M}$ represents the magnetic momentum of the rod subjected to the inductive intensity of the field of intensity h and θ, the angle which it makes with the lines of force.

$\mathfrak{M}$ is a function of θ, for the magnetising intensity of the rod is smaller in proportion as the angle which it makes with the lines of force is greater, and when θ attains a value equal to $\frac{\pi}{2}$ (*i.e.*, when it is perpendicular to the lines of force) we see at once that the rod cannot receive any magnetisation, and that according as it deviates very slightly to one side or the other of this critical position, the sign of its magnetisation is changed.

The nature of the function that connects $\mathfrak{M}$ with θ is unknown to us, but we will suppose that the value of $\mathfrak{M}$ remains constant while the rod, leaving the position of unstable equilibrium at which its magnetisation is *nil*, describes a right angle and places itself in the direction of the lines of force of the field producing mechanical work. In order to place ourselves under the most favourable conditions possible, we will assume that during this angular displacement the value of $\mathfrak{M}$ is constantly equal to that which corresponds to the position of equilibrium established when the direction of the rod follows the lines of force. It is easy to see that under these conditions the mechanical work, $\mathfrak{T}$, developed while the rod describes a quarter of a revolution is expressed by $\mathfrak{T} = \mathfrak{M}\, h$.

The rod being thus brought to its position of stable equilibrium, we will raise its temperature until it completely loses its magnetic properties, and we will make it describe another quarter of a revolution in the same direction so as to bring it into the position perpendicular to the lines of force of the field; we will keep it still and cool it until it regains all its magnetic properties. It is then ready to go through again the cycle of operations that we have just described. Designating by $\mathfrak{I}$ the intensity of magnetisation of the rod and by v its volume, we get

$$\mathfrak{M} = \mathfrak{I}\, v; \text{ whence } \mathfrak{T} = \mathfrak{I}\, v\, h.$$

On the other hand if we call T_0 and T_1 the initial and final temperatures of the rod, and c the specific heat of the alloy of ferro-nickel, m the specific volume, the quantity of heat which must be supplied to the rod and which must then be withdrawn from it in order to describe a cycle of operations is expressed by:

$$\mathfrak{Q} = c\, m\, v\, (T_1 - T_0).$$

The value of the work produced per unit of heat is therefore:

$$\frac{\mathfrak{T}}{\mathfrak{Q}} = \frac{\mathfrak{I}\, h}{c\, m\, (T_1 - T_0)}.$$

We see that it is greater in proportion as the intensity of magnetisation and the magnetic field are themselves greater.

Iron, steel, and cast-iron have been subjected to many experiments, having for their object the determination of the values of $\mathfrak{I}$ as a function of h; but unfortunately it is not the same for the alloys of iron and nickel studied by M. Guillaume, and we must content ourselves with hypothetical values which we will choose, letting ourselves be guided by the single consideration that nickel is considerably less magnetic than iron. We will assume, then, that the maximum of $\mathfrak{I}$ is about 1,000 C.G.S. units, whereas that of soft iron is equal to 1,500, unless the inductive field possesses an extremely high intensity and becomes, in consequence, difficult and costly to produce.

This last consideration will lead us to adopt for the inductive field a moderate intensity, which we will fix at 1,000 gauss.

As regards the factors which enter into the denominator of the second term of the equation, which gives $\frac{\mathfrak{T}}{\mathfrak{Q}}$, we will assume the following values:

$$c = 0{\cdot}12,\ m = 8,\ T_1 - T_0 = 50°.$$

We thus get for the value of the mechanical work (expressed in ergs) produced by an expenditure of heat equal to a small calorie:

$$\frac{\mathfrak{T}}{\mathfrak{Q}} = \frac{0{\cdot}12 \times 8 \times 50}{1{,}000 \times 1{,}000} = 20{,}800 \text{ ergs.}$$

The mechanical equivalent of a small calorie being equal to 41,690,000 ergs, we see that the available mechanical work would only represent $\frac{1}{2000}$th of the work equivalent to the quantity of heat expended. Now *the worst steam engines* consuming 30 kilogrammes of steam per H.P. hour transform into work $\frac{1}{25}$th of the available heat; they have, therefore, an efficiency nearly 80 times as great as that which we have just found.

This is not all; to make a motor of one steam H.P., we must furnish each hour to the magnetic alloy a quantity of heat equal to that which represents theoretically the work of one H.P. during this period of time (635 large calories), multiplied by the inversion of the fraction, $\frac{\mathfrak{T}}{\mathfrak{Q}}$, or 1,270,000 large calories.

But this number only represents half the flow of heat that must pass through the magnetic parts that are alternately heated and cooled, for after a certain quantity of heat has been supplied to these parts in order to get rid of their magnetic properties, it has to be taken away in order to make these same properties disappear, and these changes of temperature must take place in a much shorter time than that which represents the duration of a cycle if we would not lower considerably the feeble efficiency that we have just found. Thus it is not the movement of 1,270,000 large calories per hour that would necessitate the production of one steam horse-power, but twice that quantity or 2,540,000 calories: and the duration of these changes of heat should certainly not exceed a quarter of the time

* *Comptes Rendus*, Académie des Sciences, October 11th, 1897, p. 511.

required for the production of the mechanical work, or the efficiency will be considerably weakened, as I have said before, because if the heating and cooling were not almost instantaneous, the work produced by a given displacement of the magnetic parts would have a lower value than that calculated. It would therefore be necessary to use heating and cooling processes of extreme energy, of which we can form an idea by comparing them with what takes place in locomotives, where *a square metre* of heating surface gives passage to about 200,000 calories an hour at the most.

Thus, briefly, with the hypotheses we have assumed, the production of one steam H.P. of work would require an expenditure of 1,270,000 calories of heat per hour, which would be equivalent to the total quantity of heat produced by the burning of 150 kilos of coal.

II.

The results of these calculations are of a nature to lead us to abandon all hope of turning to account the very remarkable properties of the alloys of ferro-nickel as far as their application to the transformation of heat into mechanical work is concerned. I am, however, going to show that they may be considerably improved: 1st, by increasing the intensity of the magnetic field; 2nd, by employing a particular method of heating and cooling; by making the body which serves as a vehicle for the heat pass successively over a series of rods made of alloys in which the percentage of nickel varies according to a law determined by means of the formula (furnished by M. Guillaume)* We will now examine these three ways of increasing the efficiency.

The Augmentation of the Intensity of the Magnetic Field.—The mechanical work developed during a cycle being in proportion to the intensity, h, of the field, whereas the quantity of heat necessary to effect the disappearance of the magnetic properties of the alloys of ferro-nickel is to all intents independent of it, we may say, without making any appreciable error that the economic efficiency is in proportion to the intensity of the field.

Therefore, if this intensity amounted to 10,000 units instead of 1,000, the efficiency would be multiplied by 10. This intensity of 10,000 units, although very high, could be attained without requiring the use of any extraordinary methods, but it is certain that it could not be obtained with simple permanent magnets. However, we purposely abstain from taking into account the expenditure of energy that it will necessarily entail.

2. *Methods employed for Supplying or Withdrawing the Heat from the Magnetic Alloy.*—We have seen that, with the efficiency of $\frac{1}{2000}$, the production of a power of 1 steam H.P. would necessitate the employment of methods of heating and cooling of extreme energy. If the efficiency were brought to $\frac{1}{200}$ by employing a field of 10,000 units, the quantity of heat that would have to be supplied to, or withdrawn from, the magnetic alloy, would evidently be $\frac{1}{10}$ of that required in the former case; but its value would still be so great that we could not reasonably expect to obtain it directly from the products of combustion, on account of their low specific heat per unit of volume. The heating, and also the cooling, of the magnetic mass must be almost instantaneous. Now there is only one process that enables us to supply or withdraw from a body of small volume a considerable quantity of heat in a very short time: this is to bring it into contact with a liquid considerably hotter or colder than itself, and, moreover, to divide the body into thin plates or into wires of small diameter so as to increase as far as possible the ratio of the surface exposed to the changes of temperature to the volume of the body. This method, moreover, enables us to vary the temperature of the body alternately between two determined limits without any considerable consumption of heat, unless, however, its specific heat is not a function of the temperature alone (and this is what takes place when the body produces mechanical work). This is, moreover, the principle of the regenerators of heat formerly used in hot air engines. But, for this process to give the economic results required of it, the following conditions must be fulfilled:—(1) The body that is to be heated or cooled must not conduct the heat in the direction of the movement of the liquid, so that its temperature decreases according to a logarithmical law in the direction of the movement without its different parts tending to place themselves in equilibrium of temperature; it should, on the contrary, conduct in a direction perpendicular to the movement of the liquid. (2) We must avoid all causes of disturbance in the liquid so that the layers that are affected by the same movement should have no tendency to mix and place themselves in equilibrium of temperature. (3) A definite relation should exist between the mass of the thermo-magnet, the extreme limits of temperature that cause its magnetic momentum to vary, and the quantity of liquid set in motion during one cycle. If this relation is not observed, a great diminution of the useful effect might result. The two first conditions are easy enough to fulfil by forming the thermo-magnet of a series of plates of very slight thickness, with a breadth of 10 to 15 millimetres in the direction of the movement of the liquid, and separated from one another by an interval of 2 to nearly 3 millimetres.

Lastly, in order that the displacement of the thermo-magnet in the magnetic field should be slight while the changes of temperature are taking place, it will probably be necessary to impart to it an alternating movement like that of the piston in a steam engine; the changes of heat would then take place at the ends of the stroke. The circulation of the liquid would be alternating and would be controlled by a piston set in motion by a handle fixed at right angles on the motive handle.

3. *The Simultaneous Employment of Several Thermo-magnets Working at Different Temperatures.*—Is Carnot's principle applicable to the phenomena brought into play in the thermo-magnetic motor? It is extremely probable, as, up to the present, the conclusions that have been drawn from it when it has been applied to the study of the various manifestations of energy, in which there is a transformation of heat into mechanical work, have always been verified. If it is so in the present case the economic efficiency of the thermo-magnetic motor can only attain a high value on condition that the limits of temperature between which the thermo-magnet oscillates in order to completely, lose or recover its magnetic properties shall be as far apart as possible. Now the interval between them, in the case of the alloys of ferro-nickel, is only 50°; but by varying the proportion of nickel, the absolute value of the extreme temperatures can be modified at will, their difference remaining always equal to 50° We can thus, with the aid of M. Guillaume's formula, arrange the percentage of nickel in a series of alloys so that the richest of them shall lose its magnetic properties at 350° and recover them completely at 300°, whereas a second alloy will lose them at 300° and recover them at 250° and so on. We arrive thus at the last alloy of the series for which the extreme temperatures will be 150° and 100°. The fall of temperature of the liquid will thus amount to 250° and the efficiency will be five times as great as if only the first of the alloys were used. We could even go lower than 50° and realise an alloy, the cycle of which would be comprised between 100° and 50°.

This process would, therefore, enable us to increase six-fold the economic rendering of which we gave the value at the commencement of this article; as, besides, this same efficiency can be multiplied by 10, by employing a magnetic field of 10,000 units we see that the coefficient $\frac{1}{2000}$, the value of which we gave at first as representing the fraction of the heat displaced transformed into work, would become $\frac{10 \times 6}{2{,}000} = \cdot 03$, even *if we did not employ* the mode of heating and cooling described above.

III.

In short, we see that, if it is not impossible to utilise the curious thermo-magnetic properties of the alloys of ferro-nickel for transforming heat into mechanical work, very great difficulties will have to be overcome in order to obtain really practical results.

The question of the direct transformation of the heat into electrical work has a close connection with the one now under consideration, but it is much more difficult to treat it directly; it is, moreover, almost evident that the conclusions at which I have just arrived apply equally to this second mode of transformation. I must observe that this is not the first time that it has been proposed to utilise the thermo-magnetic properties of either iron or nickel, for transforming heat into mechanical or electrical work. Edison has tried to solve this problem,* using the property that iron possesses of ceasing to be magnetic at about 750°. But none of the conditions necessary either for obtaining a practical economic efficiency or for ensuring the rapidity of the changes of temperature were fulfilled. M. Nodon wrote to me after the publication of my first note on this subject, that he had in 1890 sent a sealed packet to the Académie des Sciences, in which he described a process consisting of the employment of a metallic gauze of pure nickel serving to close a magnetic circuit. This metallic gauze was alternately heated and cooled by means of a current of air, and the variations in the flow of magnetic force which resulted from the variations of temperature thus produced served to generate an alternating current.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

An Electrolytic Process for the Manufacture of Parabolic Reflectors.† By Sherard Cowper-Coles, Member, Assoc.M. Inst.C.E.

Glass mirrors at the present time are almost exclusively used for projectors for search lights and similar purposes, on account of the difficulty that has been experienced in producing a true metallic reflector that will not readily tarnish when exposed to the heat of an arc light. One advantage of a metallic reflector is that the rays from the carbon points are collected into a parallel beam by means of refraction only, and is not catadioptric, as most glass mirrors are. Spun reflectors are never true, as it is found in practice impossible to spin them quite true to the moulds. Experiments have been made with a view to substituting cast metal for glass, but the cost of grinding and polishing, and the unsatisfactory surface that is obtained, have resulted in the attempts being abandoned. Stamped reflectors have also been tried, but with no more satisfactory results. The present process I propose to describe to you is an electrolytic one, one of the chief features being that the surface produced requires no after polishing or trueing up. When once a true mould has been produced, any number of reflectors can be taken from it at a nominal cost. A glass mould is prepared, the convex side of which is accurately shaped and polished to form a true parabolic, or other reflecting surface. As the mould only requires shaping and polishing on the convex side, it is comparatively cheap as compared to a glass reflector, which has to be ground on both sides. On the prepared surface is deposited a coating of metallic silver, which is thrown down chemically on the glass and then polished, so as to ensure the

* Given in my note to the Académie.

* *La Nature* published in 1888 an article in which we find the methods used by this scientist described.

† Abstract of Paper read on Wednesday, February 9th, 1898.

copper backing being adherent to the silver. The mould thus prepared is placed in a suitable ring and frame (which I will describe later on), and immersed in an electrolyte of copper sulphate, the mould being rotated in a horizonal position, the number of revolutions being about 15 per minute. The copper adheres firmly to the silver, and together they form the reflector, which is subsequently separated from the glass mould by placing the whole in cold or lukewarm water, and then gradually raising the temperature of the water to 128° Fahr., when the metal reflector will leave the glass mould, due to the unequal expansion of the two. The concave surface of the reflector obtained is an exact reproduction of the surface of the mould, and has the same brilliant polish, and requires no further treatment to answer all the purposes of a reflector, with the exception that it must be coated with a film of some suitable metal to prevent tarnishing. Palladium is found to answer this purpose best, as a bright coating can be deposited rapidly to any desired thickness; the palladium resists tarnishing and the heat of the arc to a wonderful degree.

Palladium is a silver-white hard metal, and is sufficiently ductile to be rolled into thin sheets. Its specific gravity is about 12, being half that of platinum. The present price of palladium is about double that of platinum, but, its weight being one-half, the same area can be covered at the same cost. It melts at an extremely high temperature—about the same as wrought-iron. When only slightly heated in hydrogen gas, it has an extraordinary power of absorbing mechanically large volumes of this gas. Graham investigated this very curious phenomenon, and found that a piece of palladium foil, when heated below 212° Fahr., takes 240 times its volume of hydrogen, but that it had not the power of absorbing oxygen or nitrogen. At a moderately high temperature palladium assumes a blue colour, and the formation of a thin film of oxide, which it loses at a higher temperature, due to the decomposition of the oxide. Palladium is not readily attacked by sulphuric or hydrochloric acid.

In carrying out the manufacture of reflectors by this process, it is essential that the glass mould be perfectly clean and free from grease before the silver coating is applied. It has been found, however, that, if the cleaning is solely effected by chemical means, there is a great liability of the silver adhering too firmly to the glass, whereby the mould is in danger of being broken during the removal of the reflector. This difficulty has been overcome by cleaning the glass mould with a suitable paste or powder, such as peroxide of iron, then removing such paste or powder by washing the glass with a 50 per cent. solution of ammonia. It is necessary that this cleaning operation be repeated prior to the production of each reflector. After the convex side of the mould has been properly cleansed as described, a thin coating of metallic silver is applied as follows: Ammonia is added to a solution of nitrate of silver until the precipitate that is first formed is re-dissolved, then re-precipitating by caustic soda, again dissolving in ammonia, then adding glucose to the solution. Excellent results have been obtained with a silvered solution of the following components, equal parts of each being used:—Silver nitrate, 0·5 per cent.; caustic potash, 0·5 per cent.; glucose, 0·25 per cent. The surface of the mould to be coated is immediately dipped into the solution, when it becomes coated with a film of silver. The silver coating is thoroughly washed, and then allowed to dry, and the silver which has been deposited is burnished bright with a piece of cotton wool and peroxide of iron, preferably precipitated by ammonia from a dilute solution of ferrous sulphate. The cost of the silvering is found to vary from 2d. to 4d. per inch diameter. I have here a film of the silver and copper stripped from a glass mould, which is quite transparent to transmitted light, having a green tinge, but is capable of reflecting light.

The copper solution generally used is of the following composition:—Copper sulphate, 13 per cent.; sulphuric acid, 3 per cent.; water, 83 per cent. As soon as the requisite thickness of metal has been deposited, the mould, with the reflector attached to it, is placed in a bath of cold or lukewarm water, which is then raised to a temperature of 120° Fahr.; whereupon, owing to the difference of the expansion of the glass mould and the metal backing, the latter separates from the mould. The only thing that requires to be done now is to coat the reflector with an untarnishable metal. This is accomplished by placing the reflector in an earthenware pan, containing a 0·62 per cent. solution of palladium ammonium chloride in about a 1 per cent. solution ammonium chloride. The solution is used at about 75° Fahr., the current used for a 2-foot reflector being about 0·5 of an ampere, the E.M.F. at the terminals of the bath being 4 to 5 volts. An anode made out of carbon, and curved approximately the shape of the reflector, is attached to a rod, which is connected by an arm to a rotating disc which causes the anode to swing to and fro, thereby ensuring an even coating of palladium, and agitating the solution and preventing the depositing upon the reflector of particles of foreign matter which may be present in the solution.

The back of the reflector is usually varnished before placing it in the bath, to prevent local action setting up between the copper and the silver or palladium. The reflector is removed from the bath and dipped in boiling water, and then placed in boxwood sawdust, which is kept hot by means of a steam jacket. The reflector is then ready to be mounted in a suitable ring.

Reflectors made by the process which has just been described have been subjected to a number of tests, and found to withstand excessive heat without tarnishing. Salt water has been thrown on the reflectors when they have been too hot to touch, the result being that the water was driven off as steam, and the salt left as a white deposit on the reflector, which was easily removed with a wet cloth.

A reflector recently tested at Portsmouth had a number of rifle bullets passed through it, when the beam was found to be little affected. On the other hand, the first shot fired at a glass reflector splintered it to pieces.

Although palladium does not reflect light as well as a silver surface which is perfectly clean and bright, silver is found quite unsuitable, as after being in close proximity to an arc light for a short time the silver tarnishes, and the light is greatly reduced in intensity. With a palladium-faced reflector the intensity of light is found to remain practically constant, as little or no tarnishing takes place.

THE SOCIÉTÉ INTERNATIONALE DES ELECTRICIENS.

THE usual monthly sitting of the Société des Electriciens took place February 2nd, 1898, with M. Violle in the chair. M. G. Janet, in consequence of a death in the family, could not read his paper on "The Temperature of Incandescent Lamps."

M. BRANLY called attention to the fact that various experiments had been made in producing continuous or intermittent electric waves, transmitting them to a distance, receiving them, and registering them. The transmitter is a Hertz oscillator, with two spheres immersed in an insulating liquid. This oscillator is worked by a little Ruhmkorff coil, placed in a box lined with metal, and provided with a contact key for obtaining short or long discharges.

The Hertz spark resonator is replaced by a tube of iron filings. The latter, which are enclosed in a tube, and placed between two conductors, and which form a circuit with a battery and a galvanometer, offer a great resistance to the passage of the current; they become conductive when excited by an electric wave. This conductivity is destroyed by a shock, to reappear when a fresh wave strikes the tube. The sensibility is very great, and manifests itself at a distance. In 1895 M. Popoff had an apparatus constructed for receiving and registering electric waves. The receiver is a tube of iron filings placed in circuit, with a battery and a relay. The latter is put in motion as soon as the tube is struck by an electric wave at a distance. M. Branly referred to his experiments in connection with the paper read at the last sitting by M. Voisenat on "Telegraphy Without Wires."

M. BOUCHEROT then read a paper on "Industrial Condensers: on their Employment in Distributions at a Constant Intensity, and on a Self-exciting Alternator."

In industrial condensers, the quality of paper used is an important consideration. Some kinds of paper heat and keep together, others do not heat, but easily crack. The specific resistance of the paper varies from 1 to 3 megohms per centimetre.

The temperature should also be considered. In some measurements taken between 20° and 100°, M. Boucherot obtained for the insulation resistance of various condensers—for oil, 3,500 ohms at 95° and 1·45 megohms at 17·1°; for paraffin, 500,000 ohms at 99° and 10 megohms at 17°; for oiled paper, 150,000 ohms at 44°, and for paraffined paper 6 megohms at 40°. A paraffined paper condenser gave an insulation resistance of 2·6 megohms at 37°, of 700,000 ohms at 50°, and of 100,000 ohms at 80°. To obtain good working from a condenser, we must not, at present, exceed a difference of potential of 800 volts.

Various experiments have shown that, on alternating current systems, the difference of potential rises to values above the normal and pierces the condensers. We can now make condensers for 40 periods per second at 3,000 volts, at the rate of 100 francs the kilowatt, and at 100 volts for 150 francs the kilowatt. For 50 periods per second, we must reckon at 3,000 volts 50 francs the kilowatt, and at 100 volts 75 francs the kilowatt, but condensers are only advantageous for low powers.

M. Boucherot then showed the advantages of condensers, first, for counteracting the effects of self-induction, and then for distribution at a constant intensity. On an effective difference of potential is branched a circuit formed of a self-induction coil and a capacity. We can then place in derivation, either at the terminals of the condenser or at the terminals of the self-induction coil, a circuit formed of various apparatus in series. The intensity remains constant in the circuit.

The writer then discussed various other cases, and made some experiments for purposes of demonstration. In conclusion, he spoke of a self-exciting alternator, but he merely gave a brief sketch of its principle.

M. KORDA then said that some condensers had already been constructed at Buda-Pesth with an insulator of oil in vacuo.

THE ENGINEERS' STRIKE.

As the results of the men's ballot came in, they showed in favour of acceptance of proposals 28,588 and against 13,727, a more than two-thirds majority. The terms of settlement being formally agreed upon, it was arranged to resume work on Monday, January 31st. There was a good deal of kicking against the inevitable, and talk about a general organisation. This, we are certain, will for long be impossible, except some entirely new actuarial basis be built upon, with proper division, by hard and fast lines, of the funds for fight and for benefit. In its late existing form the Amalgamated Society of Engineers is a total wreck. Never was a trade struggle carried on with less turmoil and strife, and never has so huge a struggle terminated so disastrously for its originators. The men have secured nothing by the struggle. They have not even gained any recognition for even fancied principles. True, certain hitherto accomplished aims have been specifically named in the agreement, but to them have been tacked equally specific limitations not hitherto allowed a right in trades union ideas. Militant unionism has been set back to a line far in the rear of its previous outposts, and the line is fortified by the employers who have mounted guns on previously dismantled positions. Everything now depends upon the amicable working of the men under new conditions, and upon the determination of the employers to insist on a day's work for a day's pay, and to keep their plant up to modern conditions.

Labour will then begin to profit by the change and by the regaining of lost trade, and we fully believe that with these things thoroughly carried out the eight hour day will come to be general. A really earnest day of eight hours will be better for everyone than the half-hearted nine hours' day, which we hope has ceased to be. The estimates as to the proportion of the locked-out men that could be taken on again varied considerably for different towns. At one place hardly any, at another 75 per cent., and the remainder in a few weeks, were reported as probable.

In this last ballot of the men the smallness of the numbers voting is remarkable. At Paisley, Blackburn and Leeds, Dundee, Wigan and Keighley, the majority of votes were cast against returning to work, whereas in London, the place of the original mischief, the men wanted to go back to work. This sort of thing must annoy the men of the north, who, having taken up the battle for London, find themselves sold by the London executive, who, a short time ago declared they had funds to go on fighting indefinitely, and yet hardly had funds to meet weekly engagements. The hope of supplies had, in fact, kept men fighting to the last ditch, and there, figuratively, they were left while Mr. Barnes cynically abandoned them to their fate, as having no choice. The great change which the strike has shown to be coming upon the engineering trade is specially made plain in the case of a firm which finished two steamers by the aid of apprentices only, the steamers passing the trials and tests as up to standard. Why, with all the facts before them, the executive allowed the fight to go on upon the mere formality of a formal recognition by the employers of the notes appended to the clauses of the agreement, it is difficult to say. The notes were the notes of the employers, and would be cited, whether formally recognised or not, in the future. Probably the truth is that Mr. Barnes hoped by refusing the clauses to force public opinion in favour of the men, in which he lamentably failed. He then seized upon the notes, and asked the masters to say over again what they had already pledged themselves to. This delay has done trades unionism no good. Nothing more has been obtained, but only the nakedness of the treasury has been shown up and a defeat has been converted into a rout, for the men could have far better gone to work direct from the conference, while every day's delay has shown up the hollowness of the cry of the skilled man as necessary in machine production.

Finally, we should like to say a word as to the threat to carry things to Parliament. The working man to-day is full of economic heresies. He seems to think he can ask Parliament to pay wages out of funds which exist in his imagination, as though Parliament could do anything and everything. This nonsense is the result of preaching to the so-called working man as though he were a wonderful creature, all virtue and with no vices, and he has been patted on the back by M.P.'s and the like until he has come to think he is all that fancy paints him. It is all this which has led up to the conduct of the men in respect of restriction of output and general insubordination to the truth and to the principles of business morality. Their line of procedure has been followed for long past much as a train may run safely over a line of rails for a long time until it reaches a junction. In the case of the engineers they have run their train full of economic heresies until it has intersected that of foreign competition and the result we have seen. Others have seen the convergence of the lines and the advancing trains. Mr. Barnes and his friends have contrived to time the trains to arrive very much together at the point where further concessions to the men brought matters in England to the wrong side of the line for foreign competition. The strike is, however, now a thing of the past, and it is hardly likely that another can be started on the same false and mistaken issues. It will be long before such a strike can be financially possible, and in the interim educational influences have a chance to operate on men and on masters. For the moment the beaten and disappointed leaders are talking frothily about the next attempt. For the sake of the men, it is to be hoped by then that they will have obtained more intelligent leaders.

As the shops were opened on the first Monday in February, it was at first decided by the employers to take on only one-fourth of the number of men necessary to fill vacancies. This was done in order to give all shops an equal chance to obtain hands. But so many shops had already so large a complement of free labour, that it was seen there would not be places enough to go round, and word was given to take on all there was room for. This still left a lot of men out of work, for many shops were short of orders, none having been sought during the strike, and it would therefore be some time before all the strikers could be taken on. So far as we can learn, the men themselves have gone back to work in a fairly agreeable spirit, the fact being that they see plainly enough they have been following a bad lead. The employers also, we are glad to hear, are doing all they can to smooth matters and are not injudiciously flaunting a flag of victory before their late opponents. Only in one or two American papers, such as the *Western Electrician*, do we find the termination of the strike viewed with spiteful ill-nature. This journal is a sample of that fortunately diminishing section of the American people, which hopes and prays for overwhelming disaster to overtake the British nation—America's best customer. We do not think much weight need be attached to such evidently biassed statements as the writer is so evidently uninformed, but he lays all the blame on the neglect of the employers to provide improved tools—a clear proof that he knows nothing of the machine question and of restriction of output which underlay the whole dispute. But while we may excuse the western editor, what are we to say of such a man as Sir John Gorst at the dinner of the United Club which had before it the question of the relation of capital and labour. He spoke on the question in an exceedingly unpractical manner, assuming that it were better to leave work alone than to attempt it at the cost of reduced wages. This way of looking at things assumes at the outset that both men and masters are doing their best, and cannot improve so as to afford a so-called living wage. It also assumes that when articles are made in this country for which only low wages are practicable, such low wages are paid to people who, if not compelled by the employers to work for poor wages, would be working at something else for good wages. The idea is absurd. No man is compelled to work for less than he can get elsewhere, and the inference is that in badly paid trades the work is unpopular, and is only taken up by those who otherwise would be idle. But it is not by any means employers who are the cause of low wages in certain employments. It is due to the workers themselves, who rush into badly paid work rather than take up well paid work which they can have for the asking. It is customary, for example, to cry shame on the management of a certain bread company which pays huge dividends out of purveying very ordinary provisions, and is said to pay poor wages. The sole reason is that the women who crowd the doors of the company for employment and accept poor pay for long hours, have open to them far more respectable and well paid work in domestic service, which is not fashionable among this class of women. Yet philanthropists so called can always be found to condemn the wrong person, and there are those who in the recent strike condemn the employers because they have refused simply to pay away in wages more than they have made in profits, a process that to anyone but a rabid philanthropist cannot long continue. When Sir John Gorst assumes it may be necessary to throw up the sponge, he is indeed a pessimist. In the first place he does not even present the hope of doing better; in the second, as an alternative to small profits and wages, he has nothing to offer. When it is remembered that he was speaking in connection with the engineering business, of which shipbuilding, our national pet industry, is a part, are we to conclude that England had better go out of business at once? Sir John spoke just as if he had been of opinion that the recent strike was a protest by the men against a starvation reduction in wages. So at least his reported speech reads, and he ought to have known better. The public at large did know better, or very soon learned the facts, and the strike was really crushed before it had existed a fortnight, and everyone saw this except the men themselves, and even they saw it sooner than their leaders, who tried to buoy up their followers by extolling the German and American subscriptions.

We hardly think that English workmen will be such fools to be caught by the high sounding "brotherhood of labour" business in the future. During the whole strike for eight hours, the selfish German workmen did not, so far as we can learn, make even the shadow of a demand for the reduction of their own 12 hours' day, which would have assisted their dear English bulldogs. They simply subscribed a few pfennig each, and raked in the wages for the work the English would not do, and unless the English workmen will study these things for themselves, and not put their lives into the hands of the first stump orator who gets up and froths, they must expect foreigners to treat them as fools.

TESTS OF THE SYNCHRONOGRAPH ON THE TELEGRAPH LINES OF THE BRITISH GOVERNMENT.*

By ALBERT CUSHING CREHORE and GEORGE OWEN SQUIER.

In April, 1897, a paper was read before the American Institute of Electrical Engineers, describing the general principles of the synchronograph and the experiments at that time completed in developing it.† Since then opportunity has been presented to make trials on actual lines of considerable length and having different distributed capacities. The tests were made over loops of varying lengths from the General Post Office, London, where both transmitters and receivers were located.

The apparatus available for experiment comprised a high frequency alternator, giving practically harmonic waves from 50 to 720 complete waves per second; actual telegraph lines with values of K R varying from 0 to 261,000 and resistance varying from 0 to 10,000 ohms; an artificial submarine cable representing within 1 per cent. of accuracy an actual cable of 180 knots in length, and also the latest types of Wheatstone transmitters and receivers, with adjustable condensers, &c.

The longest loop tried was 1,097 miles, from London to Glasgow, Aberdeen, Edinburgh, and return to London by a different pole line. This contained some iron wire and also 48 miles of underground cable, and a total value of K R equal to 261,000.

* Abstract of a report to the Postmaster-General of the United States, read before the Franklin Institute, January 19th, 1898, and published in the *Electrical World*.

† See Electrical Review, May 7th, 1897.

It was found in the course of trials with the different apparatus that it was possible to operate the Wheatstone receiver without alteration by the synchronograph transmitter, and a test was made over the longest line to compare the efficiency of the two transmitters when operating the same receiver under identical line conditions. The surprising result was discovered that the synchronograph could operate the Wheatstone receiver approximately three times as fast as the Wheatstone transmitter on any line, provided the mechanical limit of the receiver is not already reached. The Wheatstone system operated from London to Aberdeen ordinarily employs two automatic repeaters to increase the speed. Without any repeaters the synchronograph operated the Wheatstone receiver over this line practically up to its mechanical limit. By the synchronograph method of transmission it thus becomes possible to operate Wheatstone receivers at the present speeds without repeaters anywhere in the British Islands.

One of the most important results of the trials to be described has been to emphasise the probability that the sine wave possesses superiority over other forms of wave for any speed, slow or fast.

The messages are prepared for the Wheatstone transmitter by perforating paper tape with two rows of holes at the proper intervals to secure correct signals, one row on each side. In the centre, between these two rows of holes, runs an uninterrupted series of smaller holes, which serves to feed the tape regularly through the transmitter.

A characteristic of the transmitter is the fact that the contact for the electrical circuits is not made through the holes in the paper, as in some transmitters, but by small steel rods, which pass through the holes in the paper, contacts are made and broken in another part of the apparatus by means of levers. Only the positive currents cause the receiver to make a mark. A dot, together with the accompanying space corresponds to a complete wave of current. A dash with its following space occupies twice the time of a dot with its space, and corresponds to the time of two complete waves, although in reality it is a single wave with the positive portion three times as long as the negative, and thus the mark for a dash is about equal to three dots.

The chief characteristics to be noted are that the waves of impressed E.M.F. are square-topped, and those for a dash are longer than for a dot.

An essential part of the receiver is a polarised relay consisting of a permanent magnet and an electro-magnet. The armature of the receiver, to which the recording wheel is attached, is moved in one direction for a direct current and in the opposite direction for a reversed current. A small recording wheel is kept moistened with ink, and every positive current drives it against the paper, while a negative one raises it from the paper. The paper tape is driven forward by clockwork, and thus a series of marks is made upon the tape corresponding to the positive portions of any set of current waves.

In practice it is found that, when connected directly to the line and the return, and operated by the transmitter, the speed obtainable over most lines can be increased by the use of condensers shunted by non-inductive resistances and inserted in the main line. Common values of the resistance and capacity are about 8,000 ohms and 10 to 20 microfarads, which would vary according to the line.

The details of the experimental transmitter used in the synchronograph experiments were practically the same as those employed in the original experiments, and described in the first paper to which reference has been made. The messages were prepared by fastening strips of paper upon the metal surface of a large wheel geared directly to the shaft of the alternator as there described.

As it was desired to make tests over a considerable range of frequencies, the small Pupin alternator used in the first experiments was again utilised for these trials. The alternator was driven by a 1 H.P. Lundell motor, supplied from 100-volt constant potential mains, and a storage battery was available for the excitation of the rotating field of the generator. Since the generator is, in fact, four alternators of 18, 22, 26 and 30 poles respectively, and the motor could be run regularly at very slow speeds as well as high, this combination with a field excitation, which could be varied at will, permitted a wide range of frequencies at any desired voltage. Transformers were used when desired. For the most rapid speeds the chemical receiver, using the formula of Delany, was employed with the synchronograph. The paper was prepared and used in the form of sheets instead of tape.

The lines first used in the tests of August 8th ran from London *viâ* Leeds to Newcastle-on-Tyne, and return to London *viâ* York.

With no earth, messages were received with ease at a frequency of 652 cycles, or 1,304 alternations per second. This frequency was limited by the fact that the greatest number of poles to the generator was 30, and the number of revolutions to produce this frequency was 2,608, beyond which it was not then thought advisable to go for fear of injuring the machine.

With earth and a total value of K R equal to 81,518, a frequency of 165 cycles, or 330 alternations per second was reached.

To obtain a longer line with a greater value of K R, a second loop was made up from London *viâ* Leeds to Glasgow, and return *viâ* Edinburgh, Newcastle-on-Tyne, and York to London.

As before through this line without earth, K R being 31,771, a current was sent having a frequency as high as safety to the alternator permitted, viz., 652 complete waves per second, and no limit of speed due to line damping was reached, the messages being received with perfect clearness. With earth and K R = 127,082, no records were received at all on this date on account of not having at hand a suitable transformer to produce high enough potential at the slow speed of the alternator necessary. Before the next trials were made a suitable transformer was available to deal with a value of K R much larger than the above.

To test the fact that the messages were actually passing through Glasgow, and that the records were not being caused by leakage currents across the line at some point, the circuit was broken by the operator at Glasgow at a certain time, and restored five minutes later. Before and after the line was so broken the messages were transmitted readily, while during the time it was broken not the slightest record could be obtained.

An instructive experiment, illustrating forcibly the influence of increase of distributed capacity upon aerial wires, was that of suddenly plugging in and out the earth connection, thereby practically changing the capacity of the line four-fold, when at the instant the earth was connected the motor would slow down and labour under the increased load.

On Thursday, August 12th, it was decided to try the synchronograph with the Wheatstone receiver, which was at hand in the same room. This was done, and without any alteration of the receiver whatever it responded readily to each wave of current from the alternator. Messages were then correctly transmitted and received. This was done by two different methods. First, the messages were interpreted by the portions of current omitted, as described in the former paper, the omission of a single mark denoting a dot and two marks a dash, the marks themselves meaning spaces. Second, the presence of the marks was used for dots and dashes, and one mark denoted a dot, while two or three consecutive marks denoted a dash. The marks are all regularly spaced, and the eye experiences no difficulty in reading the dash, even though it is made up of two or three separate consecutive marks instead of a single long mark, since the length of the dash is of more moment than the continuity of the mark.

These preliminary tests developed the fact that messages could be received by the Wheatstone receiver in the laboratory faster with the synchronograph than with the regular Wheatstone transmitter. When this discovery was made the engineer-in-chief desired to make a more extensive series of experiments and try the synchronograph with the Wheatstone receiver over actual lines having a value of K R sufficient to reduce the speeds. As the Wheatstone receiver was to be used with the alternating current, the first thing wanted was a knowledge of its constants. The inductance of the instrument measured by the impedance method was found to be ·875 henry for a single coil and 3·46 henrys for the coils in series. When the coils were connected so as to give opposing magnetic effects the measurements gave an inductance of ·187 henry. The two coils of the receiver are wound together, the two wires being wound as one upon the spools in such close proximity that the mutual induction between the coils is at its maximum, and is nearly equal to the inductance of each coil. In such a case the inductance of the two coils in series should equal four times that of a single coil if there were no magnetic leakage, and when connected in opposition the inductance would vanish. This agrees approximately with the measurements when allowance is made for small magnetic leakage.

When the receiver coils are connected in parallel the inductance is practically the same as that of a single coil, since the two coils are like a single one having larger wire, the number of turns being identical.

Thus, with a frequency of 650 cycles per second, the reactance is many times larger than the resistance of the coil. In either case of a series or parallel connection of the coils it is 22·75 times as much.

When the receiver is used with reversing currents, such as are employed in the Wheatstone system, or with alternating currents, the impedance is the important element, and the value of the resistance makes very little difference, provided it bears so small a ratio to the impedance.*

When the synchronograph was used with the Wheatstone receiver the resistance with its shunted condenser, described above, was removed from the line, and the condenser shunted directly around the receiver. The receiver and condenser thus form a resonant circuit, and by properly choosing the condenser it is possible to increase the receiver current materially, making it larger than the line current. This is the benefit of using a condenser, but the capacity for the best effect should vary with the frequency of alternation. By knowing the inductance of the receiver and the frequency, the condenser capacity can be readily calculated. The value of the capacity for any frequency is not very critical; that is, a condenser will improve the working for a considerable range of speed.

With lines having a low value of K R, the speed of the Wheatstone system is limited to about 600 words per minute, as this is found to be very near to the mechanical limit of operation of the receiver, due to the inertia of the moving parts, the spattering of ink or other causes.

A copper aerial line having K R equal to about 30,000 will reduce the Wheatstone speed to about 400 words a minute; and when a line exceeds this it is customary to insert an automatic repeater, by which the speed is maintained over longer distances. Speeds of 400 words a minute are regularly maintained in England in commercial working, while the limit of the commercial working in the United States is considerably lower, about 200 words per minute.

The speed of the synchronograph transmitter and a chemical receiver would be greater than that with the Wheatstone receiver, because of the shorter code permissible with this receiver. There would then be no limit at 600 words due to the mechanical construction, so that the value would run up into thousands of words per minute. The speed cannot be given, as the experiments have not yet established the law of speeds for this combination of instruments.

Opportunity was presented for tests of this method of transmitting signals over the artificial cable belonging to the British

* With the receiver in circuit with the main line the inductance of the former should be considered in comparison with the resistance of the whole circuit, and its combination vectorially therewith affects the latter very slightly.—EDITOR.

Post Office, and making direct comparisons of the alternating current method with the present Wheatstone system over the same cable. This cable, which represents within 1 per cent. the real cable used from England to the Continent, to Ireland, the Channel Islands, &c., is made in 60 sections of 3 knots each, making a total of 180 knots or 207·5 miles. Each section has K equal to 1 microfarad and R = 33 ohms, making total K = 60 microfarads and total R = 33 × 60 = 1,980 ohms, and total K R = 118,800. The cable is of the type in which the distributed capacity is obtained by condensers placed at regular intervals along its length.

Through this cable, with a voltage of 110, messages were sent at a frequency of 93·6 periods, or 187·2 alternations, per second, using the synchronograph and the chemical receiver. The next experiment was with the Wheatstone system transmitter and receiver, using 100 volts constant potential, and a speed of 120 words per minute, equivalent to 72 complete waves per second, was reached by the post office officials.

From a long experience in the British service the basis which is there used to calculate the number of words per minute in terms of complete cycles of current by the Wheatstone system is 36 complete cycles = one word, or ·6 of a complete cycle of current per second equals one word per minute. This basis has, therefore, been used throughout in calculating the comparative speeds, using the synchronograph with the Wheatstone receiver, so that the comparative results given are independent of the length adopted for a dash, or indeed of the particular code employed.

The cables from England to the Continent are not at present operated by the Wheatstone system, although by so doing the speed would undoubtedly be increased; but the Hughes system, by a present international agreement, is employed. By the Hughes system the messages are printed on a tape, which can be mounted on a blank and delivered.

With the experience already gained and the constants of the Wheatstone receiver measured, a wider range of experiments was planned, to include tests over each line for speed as follows:

(1) Wheatstone transmitter and receiver.
(2) Synchronograph and Wheatstone receiver.
(3) Synchronograph and chemical receiver.

Two other lines were made up, which, being used both with and without earth, were equivalent to four separate lines. One of these was a loop from London *viâ* York and Leeds to London with values R = 2,783, K = 11·95, K R = 33, 257, and K R with no earth = 8,314.

NEW PATENTS AND ABSTRACTS OF PUBLISHED SPECIFICATIONS.

NEW PATENTS.—1898.

[*Compiled expressly for this journal by* W. P. Thompson & Co., *Electrical Patent Agents*, 322, *High Holborn, London, W.C., to whom all inquiries should be addressed.*]

18,718A. "Improvements in, and relating to, electric railways and tramcars." S. H. Short. Dated February 3rd. (Date claimed under Patents Rule 19, August 12th, 1897.) (*Complete.*)

2,433. "An improved system of adapters, to adapt all existing fittings for electric lighting to armoured, sheathed, or other concentric cables." H. F. Phillips. Dated January 31st.

2,455. "Improvements in electric contacts suitable for railway signalling and other purposes, and apparatus for use in combination therewith." R. Burn and A. C. Brown. Dated January 31st.

2,479. "Improvements in terminals for electrical connections, especially adapted to incandescence lampholders." G. Byng and H. Bevis. Dated January 31st.

2,485. "An improvement in electric arc lamps." C. Oliver. Dated January 31st.

2,487. "Improvements in apparatus for distributing electricity." H. Pengelly. Dated January 31st.

2,495. "Improved method of insulating electric apparatus and conductors." J. L Berthet, M. Mollard and L. Dulac. Dated January 31st. (Date applied for under Patents, &c., Act, 1883, Sec. 103, July 2nd, 1897, being date of application in France.)

2,522. "An improved electrical striking mechanism for bells." A. Eckstein and H. J. Coates. Dated February 1st.

2,538. "Improvements in, or in connection with, the electrical propulsion of road vehicles." G. Wilkinson and L. W. Holmes. Dated February 1st.

2,551. "An improved combined electrical dynamo and motor." T. Cooper. Dated February 1st.

2,571. "Improvements in electro-dynamic elements." C. Vallot and E. Pauze. Dated February 1st.

2,572. "Improved paper carriers and spacing mechanism applicable for use on typewriters or linotype machines, telegraphic, printing, and recording instruments." A. G. O'Farrell, J. E. Schumacher and W. R. Makins. Dated February 1st.

2,580. "Improvements in electric lighting media." H. A. Kent. Dated February 1st.

2,584. "Improvements in the manufacture of electric glow lamps." W. L. Wise. (C. Pieper, Germany.) Dated February 1st.

2,591. "An improvement in electric plating." F. T. Harris. Dated February 1st.

2,604. "Improvements in systems and apparatus for electric time control." W. P. Thompson. (The Self-Winding Clock Company, United States.) Dated February 1st.

2,618. "Improvements in supports, chiefly designed for electric incandescent lamps." L. Weldon. Dated February 1st. (*Complete.*)

2,669. "Improvements in electrical cut-outs." W. McGeoch, Jun. Dated February 2nd.

2,670. "Improvements in electrical keyholder and analogous switches." W. McGeoch, Jun. Dated February 2nd.

2,684. "Improvements in apparatus for the electro-deposition of metals." F. Fisher, Benjamin John Round, Benjamin James Round, and A. Round. Dated February 2nd.

2,723. "Improvements in electric arc lamps." H. Crudgington. Dated February 2nd.

2,734. "Improvements in, or relating to, electric incandescent lamps." A. J. Boult. (C. Duvivier, Belgium.) Dated February 2nd.

2,735. "Improvements in, or relating to, dynamo machines and electric motors." M. H. C. Shann and R. E. C. Shann. Dated February 2nd.

2,761. "Improvements in high tension electric switches." E. W. Cowan and A. Still. Dated February 3rd.

2,770. "Improvements in holders for incandescent electric lamps." G. Jaeger and H. Bender. Dated February 3rd. (*Complete.*)

2,784. "Improvements in electric switches." O. C. Immisch. Dated February 3rd.

2,788. "Improvements in electric incandescent lamps." R. B. Roxby. Dated February 3rd.

2,805. "Improvements in electrical tumbler switches." H. Crudgington. Dated February 3rd.

2,814. "A new or improved manufacture of insulated wire for electrical purposes generally." J. F. Brennan. Dated February 3rd.

2,819. "Improvements in electric cigar lighters." W. F. Kessler. Dated February 3rd.

2,849. "Improvements in electric switches." A. E. Tanner and F. A. C. Leigh. Dated February 4th.

2,871. "Improvements in electric furnaces." W. H. Graham. Dated February 4th.

2,876. "Improvements in electric lamp bulbs." J. Atherton and C. M. Downie. Dated February 4th.

2,891. "Improved announcing and recording apparatus applicable to telephones." F. B. Grunert. Dated February 4th. (*Complete.*)

2,904. "Improvements in electric heating and melting, specially applicable to the metal pots of linotype machines and the like." The Linotype Company, Limited, J. Place and M. Barr. Dated February 4th.

2,967. "Improvements in electro-depositing anodes." H. L. Haas. Dated February 5th. (*Complete.*)

2,968. "Improvements in electric switches." R Belfield. (G. Wright, United States.) Dated February 5th.

2,991. "Improved double arc lamp." W. Mathiesen. Dated February 5th. (*Complete.*)

2,998. "Improvements in and relating to the decomposition of alkaline salts by electrolysis and in apparatus therefor." J. Greenwood. Dated February 5th.

2,999. "Improvements in transmitters of Morse telegraphic apparatus for continuous and alternating currents." C. Rossi and P. Forcieri. Dated February 5th. (*Complete.*)

ABSTRACTS OF PUBLISHED SPECIFICATIONS.

[*Copies of any of these Specifications may be obtained of* Messrs. W. P. Thompson & Co., 322, High Holborn, W.C., *price, post free,* 9d. (*in stamps*).]

1896.

21,236. "An electric regulator." W. Emmott. Dated September 25th, 1896. The brightness of lamps or the strength of a current through a circuit is controlled by means of a self-induction coil. The coil may be in sections and the current may be sent direct or through one or more of the sections by means of a suitable switch; or the core may be movable within or in relation to the coil by means of a switch lever.

21,293. "Improvements in electrical door bolts." S. F. Page. Dated September 25th, 1896 The bolt is arranged to be shot or withdrawn or both shot and withdrawn by an electro-magnet. A bolt is shown which is shot by a spring and withdrawn by a magnet, the circuit of which may be closed by a person in bed, for instance. A metallic rod on the back of the bolt operates an alarm when the bolt is withdrawn. Two electro-magnets may be arranged around the bolt, one for shooting and the other for withdrawing it.

ELECTRIC TRACTION AT THE MECHANICAL ENGINEERS.

EVEN a lapse of three months since the adjournment of the discussion upon Mr. Philip Dawson's paper before the Institution of Mechanical Engineers has not proved sufficient to cool down the thirst of some English engineers and manufacturers for Mr. Dawson's blood, in consequence of what was considered on his part undue advocacy of American traction methods; and more than one of the speakers at the renewed discussion felt obliged to put in a few good words for the paper and its author, as being worthy of more praise than censure.

Probably if more real and unbiased experts in this field had joined in the discussion, it would have been clear that, as often happens, both sides were right and both were wrong; the fault with each lay in too hasty and comprehensive a generalisation.

We ourselves have been accused in more than one quarter of advocating the use of American designs and plant in electric traction work on this side; whereas, what we have always said, and what we still maintain is, that we do not need to go to the United States (in spite of the valuable and long experience they have had over there) for steam engines, dynamos, generators, boilers, tramcar bodies, switch gear, trolley wire, or numerous other essentials to an electric tramway; but when it comes to motors and controllers, as well as a series of designs for car trucks capable of enduring the severe work entailed upon motor cars, purchasers on this side may well pause before deciding upon home-made articles turned out by makers without a tithe of the experience possessed by Americans, who have gone through the costly mill of "trial and error." Moreover, these latter items are now being made in the States in such large quantities—at a low price even allowing for freight, and of high efficiency—that English makers cannot hope to compete in this direction for some time with any great measure of success.

While, therefore, the members of the Institution who joined in the debate, may have been right in criticising Mr. Dawson's advocacy of things American as of far too sweeping a character, they might with advantage be reminded that we have not as yet, in this country, surpassed, or even equalled, American methods and appliances of all kinds.

In regard to the question of engine types suitable for traction, there seems but little need to add any words to the remarks made by Mr. Mark Robinson. It is ludicrous to specify for a governor that shall govern an engine, and an engine that shall be governed, to within less than 1 per cent. of the normal engine speed. It is not as though the cars must be, or are, run with an unvarying pressure: with lighting it is different—a slight variation in engine speed tells at once upon the lights—but who knows of it when the line voltage of a tramway varies 40 or 50 volts in 500, or what practical difference does it make to the service? The cars at the end of a long line may slow off a little, but the variation is only momentary, and cannot have any serious sustained effect.

So long as an engine is not overloaded, and has automatic expansion gear, with a governor to prevent racing, it ought to work perfectly well, and the particular decimal fraction of 1 per cent. variation in speed is not worth troubling about. Even if it were, we have plenty of engine builders in this country who can turn out engines equal to, if not better, than the American-made articles, and with as good, if not better, governing powers.

Turning to one other point which cropped up rather prominently at this discussion, it may be worth while emphasising again the real reason for the want of progress in electric traction here as compared with America. One speaker seemed to think that the reason was because we have much better roads than are usual in the States; but if so, have we a greater number of public road vehicles, such as omnibuses? Certainly not, and, therefore, his argument falls to the ground at once. As a matter of fact, the average passenger-car-mileage density is, we believe, greater in this country than in the States, so that such tramways as we have are as much used in proportion as are those in America.

The true reason for greater development across the Atlantic is obviously that which other speakers insisted upon, viz., the absence of absurd legislation and official restrictions, such as those embodied in the Tramways Act of 1870, the title of which offers the choicest piece of sarcasm we ever remember to have seen:—An Act to *facilitate*, &c., the construction, &c., of tramways!! In driving this truth home, Sir Frederick Bramwell appears to have spoken at the meeting with his official muzzle removed; and the fact is worth noting that the same official referee called in to adjudicate upon the value of a tramway, &c., under the Tramways Act, should, when speaking as a private individual, criticise so strongly the results of the very Act he has practically been called upon to administer.

A strong contrast is noticeable between the remarks of practical men like Mr. Robinson, who dealt only with the points they specially understood, or were qualified to discuss, and the more or less vague and general utterances of the "professors." Why, for instance, should a man of so high a capacity as Prof. Unwin advocate the use of conduit lines instead of the trolley, and mention as an argument that 200 horses had been killed in Boston? Surely he knows the enormous cost of a conduit line, and that if one is being put down in New York, many others (in the shape of cable roads) elsewhere are being replaced by the trolley. There is only one New York, and the conditions of tramway work there are almost unique, just as they are in London. As for the horses, if a blizzard *will* persist in coming every few years, breaking down wires of every sort, it certainly seems wiser to employ a trolley system that can be easily repaired, and is usually less liable to stoppage, than a conduit line, even at the risk of shocking a few horses to death. It takes precious little current, anyway, to kill a horse, and if public convenience is preferred the horses must either go off the streets altogether or take the risk. The average horse would, we think, prefer to take the one-in-a-million chance of being shocked to death rather than the one-in-a-hundred chance of being worked to death on a tramway in a couple of years.

In concluding this notice of the discussion, a word of admiration ought to be put forward in regard to the persistence with which the subject of bicycle-wheel fly-wheels is introduced by the inventor or deviser. Should a paper be announced for any of the Institutions wherein there is the least reference to a fly-wheel, so surely does that familiar diagram appear on the wall or the blackboard, accompanied by figures and formulæ sufficient for two ordinary college lectures. Mr. Dick was always very fond of introducing King Charles's head into conversations not always connected therewith. The inventor of tangential fly-wheel spokes had more excuse for bringing up his pet subject at the Institution discussion, and he made the most of it. There is much to be said for his device, when the old-fashioned forms of fly-wheel are considered; but Mr. Robinson knocked a good deal of ground from under the feet of this idea (if it can be said to have any) by showing that the disc form of fly-wheel, with small diameter, is quite good enough with high-speed, short-stroke engines.

We shall await Mr. Dawson's written reply to the discussion with interest. He has, at any rate, plenty of points to deal with.

Storage Battery Traction.

SOME time ago we commented upon the Englewood-Chicago storage battery line, giving particulars of the power house, plant, &c., when equipment was going on, and anticipating further information after actual work had begun. Tests—of a rather qualified nature, so far as their practical value is concerned—have lately been made on the generating plant and batteries, and the figures derived therefrom are to be found in another part of this issue of the ELECTRICAL REVIEW. So far as the engine house plant is concerned, with coal at 7s. 8d. per ton (giving 10,145 B.T.U. per lb.) the net cost of fuel per kilowatt-hour at the switchboard was about ·305 of a penny. The batteries gave an apparent energy efficiency of 60 per cent., but quite an insufficient series of charges and discharges are taken for this result, and we imagine it to be the case (as we expected) that at least a year's working must be taken before any effort can be made to get at the exact state of affairs in battery working. By the end of that time the balance-sheet ought to be as good a test as any of the possibility of using battery traction with reasonable hope of success from an economical standpoint. As a rule it is an all sufficient test, but there has been in time past too great a tendency to bolster up storage battery traction by the manufacturing interests engaged, irrespective of absolute results. The battery cars appear to have required 1·41 units per car mile at the charging table, and about ·87 unit per car mile at the motors, equal to 10 lbs. of coal per car mile. The difference, ·54 unit, represents the loss per car mile in the battery. We shall not be at all surprised if further experience shows this loss to be continually greater as the battery deteriorates with use. No figures are given as to the cost of labour or maintenance, so that final judgment in regard to this instance of a storage battery worked line must still remain suspended. The line is evidently of a very level nature, otherwise we should expect motor cars weighing nearly 12 tons when fully equipped would require a considerably greater consumption of energy per car mile than that above named.

Post Office Telegraphs.—The Postmaster-General has appointed Mr. Edward May to the Controllership of the Central Telegraph Office rendered vacant by the retirement of Mr. H. C. Fischer, C.M.G. Mr. Thomas Barlow will succeed Mr. May as Deputy Controller.

ENGLEWOOD AND CHICAGO ELECTRIC STORAGE BATTERY ROAD.*

Ever since the consolidation of storage battery interests in this country, electrical engineers have looked forward with a feeling of satisfaction and vindication to the time when the storage battery would displace the uncomely overhead and expensive underground trolley. The problems which had up to that time occupied the minds of a few investigators, were now being attacked by numerous inventors desirous of producing a light weight accumulator, one which would not deteriorate rapidly, and a generally practical system of handling storage roads.

While these questions received the closest attention of electrical engineers, the steam generating and transmitting, as well as electrical machinery, were being marvellously developed. But while we heard of storage batteries performing many useful functions in central stations, the only roads worthy of mention whose cars were equipped with accumulators, were those of Berlin, Paris, Vienna and Birmingham. On the other hand, the Metropolitan Railway Company of New York, after a thorough investigation of all existing methods of street car propulsion, adopted the electric conduit system over a large network of thoroughfares.

We have watched, meantime, in conjunction with everyone interested in electric traction, ever since its inception in 1895, the progress and success of the Englewood and Chicago electric storage battery road, and now that the results of carefully executed efficiency tests have been made available, we take pleasure in presenting below some of the results and conclusions of these tests to our readers. During last summer over 20 motor cars were operated, often with trailers, and thousands of people were carried each day. The tests were conducted under actual operating conditions, no effort being made to obtain results better than might be expected in everyday service. The engines developed a total of 232 72 horse-power; the electrical output was 186 9 horse-power, showing an efficiency of 80 per cent., the average all-day efficiency being 79·3 per cent. The log of the boiler tests shows that the steam pressure was 168·3 lbs., and that 8·22 lbs. of water were evaporated per pound of combustible from and at 212° F., and that the boilers developed 149 horse-power each; 62 86 per cent. of the total calorific power of the fuel was utilised. The results of the tests on engines, dynamos and auxiliaries show that 18 lbs. of dry steam were used by each engine per indicated horse-power hour. The average output of each generator was 128·3 kilowatt, which was 67·5 per cent. of full load. The load factor was ·82, and the watt hours per pound of coal 155·2. The cost of coal was $1.90 per ton, and its cost per net kilowatt hour ·611 of a cent. The conditions of the test were not favourable, however, as the steam pressure was lower than it should have been and the vacuum was only 24·25 inches. The engines were also overloaded during the entire run and were not operated at their rated speed. The average percentage between the horse-power developed in the cylinders and the electrical horse-power delivered on the switchboard is shown to be 79·27 per cent., which is very satisfactory, and the efficiency of the generators (running 32 per cent. below their rated capacity) is 93·1 per cent. The total station efficiency from coal pile to switchboard is 5·58 per cent. As a matter of comparison we may state that the efficiency of the Chicago Edison Company's Harrison Street station, producing electrical energy for ·3 of a cent. per kilowatt hour, is only 4·61 per cent.

To make a fair test of the batteries, 110 trips were made on one day and 123 trips on another, giving a total of nearly 3,500 car miles. The results of these tests show the following:

Kilowatt hours at switchboard per car mile, 1·37 and 1·63 for the two days, respectively; pounds of coal per car mile, 9·45 and 10·50; cost of coal per net kilowatt hour, ·655 and ·611 of a cent; cost of coal per car mile, ·897 and ·966 of a cent. It should be remarked that there was a coating of ice upon the rails during the latter part of the second day. The total number of stops during four trips was 57, and the average speed of the cars was 11·84 miles per hour. Two efficiency tests of the battery give results of 58·6 per cent. and 62·32 per cent., respectively. These results, however, show the efficiency in actual service, but do not represent the possibilities of the batteries. All these results have been carefully plotted in the form of curves, including acceleration and current curves.

While the figures given are very gratifying, it should be stated that the tests do not demonstrate the best results that may be expected of storage battery traction, and were not made for that purpose. The primary object of the test was to determine where improvements could be made, and if this is kept in mind when comparing the results with those obtained on a trolley system of about the same size, it will be seen that the cost of fuel for accumulator traction of something less than one cent per car mile is very favourable to storage battery traction. After the improvements suggested by the tests have been made, and better coal than was used on the test, at a cheaper price, has been secured, the fuel cost per car mile should be brought well within one-half cent. The batteries have operated from 8,000 to 14,000 miles and are standing the service remarkably well, so that the maintenance account up to the present has been comparatively small.

The tests were in charge of Mr. George A. Damon, consulting engineer, who was ably assisted by Prof. T. P. Gaylord and a corps of students from the Armour Institute of Chicago. In conclusion we venture to express the opinion that the experience gained by the enterprising Englewood and Chicago Street Railway Company will benefit all interested and engaged in electric street railway development, and that it will lead to further improvements in accumulators, and the more extensive introduction of storage battery traction in the United States.

* New York *Electrical Engineer*.

THE VENTILATION OF THE METROPOLITAN RAILWAY TUNNELS.

We are in receipt of a pamphlet from Mr. Robert Cox, M.P., on the above subject. It appears to have been compiled by Mr. Ernest Callard, of the London Chamber of Commerce, and to be essentially the evidence before the Board of Trade Committee of Inquiry of Mr. Jas. Keith. Mr. Keith practically confines himself to positive fan ventilation by means of slow running fans placed midway of the stations, and we are glad to see that an absence of sulphurous smoke from the tunnels of the South London electric lines is not allowed by Mr. Keith to stand for ventilation.

The Metropolitan Railway may be foul with sulphurous fumes, but it is probably little worse than the South London line, which has not the advantage of germicide smoke to disinfect it. We do not believe in this purification of tunnels by choking fumes of sulphur, but an electrical line ought not to be put down without any attempt at ventilation. Mr. Callard shows that the Metropolitan Company hold their powers under their Act of 1854, which gives them full power to use any sort of motive power they like to employ, *without any approach to Parliament for further powers*. This being so, he questions the honesty of the company in procuring the insertion of inspired paragraphs in the press that they are seeking Parliamentary powers to adopt electric traction. All this is to beguile the public; as to which, however, there may be two opinions, as we shall show later.

It is certain that electric traction would prove a fair cure for the Metropolitan fumes. Being so near the surface, there would always be a change of air at the blow-holes sufficient to purify the tunnels of the only then possible pollution due to the presence of a certain number of people passing through.

The deeper-buried electric line in South London cannot purify itself, and is not even arranged, as it has been claimed to be arranged, so that the trains will assist ventilation. The trains churn the air, they do not push much out. Yet they might easily have been made to do so, and the otherwise necessary fans avoided. Any mining engineer would have shown how to ventilate the South London tunnels by the aid of a few brattices. As it stands, this line is but poor testimony to the boasted purity of electric traction.

It is worth note that on the Metropolitan line, at Gower Street platform, Dr. Haldane found 89·4 parts of CO_2 per 10,000, or over 22 fold the atmospheric normal. The committee would draw the maximum limit at 15 to 20 parts. As to the beguiling of the public by asking powers from Parliament, there is another side to the question. The company may have the legal right to use any motive power they wish to use, but rights are of little use unless supplemented by financial ability, and it is the financial ability which we understand is the real object of the Bill. Money is required to equip a railway for electric traction, and when this has been done, it will be time enough to apply mechanical ventilation, if such is needed. We do not believe it will be needed. In a shallow buried railway, the movement of the trains and the natural current caused by wind pressure acting at the open stations will probably be ample to keep pure the tunnels when these are free of the locomotive products. Such means, however, are quite inadequate to deal with deeply buried lines. At one time there was a good deal of nonsense written about piston trains, which would clear out the tunnels in front of them, and draw in fresh air behind them. As carried out with each tunnel opening into the same station at each end, the piston effect has resolved itself into a mere horizontal circulation of air from south to north by the up tunnel, and back again by the down tunnel to the south. There has been no serious attempt to let in fresh air from the surface, and to expel foul air to the surface, by any systematic piston effect of the trains. The thing is feasible enough, no doubt, and if not feasible, it ought not to have been seriously advanced. These deep tunnels are multiplying all over London, and they will have to be ventilated in some way. In the report before us, a Mr. Morrison is quoted to the effect that 1 lb. of coal burned is equivalent to the pollution of a tunnel by 500 people. This is an entirely wrong view. The amount of carbonic acid gas produced may be equivalent, but so is the amount of this gas produced from an ounce of graphite and an ounce of diamonds. The latter equivalence no more determines the market price of diamonds and of graphite than does the former measure the real pollution. It is not so much the presence of CO_2 that is harmful as the toxic poisons, the wasted organic tissues, the organic nitrogenous substances—in short, "the rich steams of sweet humanity" so ably discoursed of by Mokanna. These are what render the South London line so objectionable, and what future lines should have a care to eliminate.

MORE THIRD RAIL SYSTEMS.

It is most surprising to see the frequency with which American inventors make efforts to improve upon the details of some well known principle, where an English engineer would rather break fresh ground altogether and try absolutely new methods instead of changing parts of a mechanism.

Thus, in a recent number of the *Electrical World*, were described and illustrated a couple of so-called "third rail systems," both of which have evidently had a considerable amount of trouble and ingenuity spent upon them by their devisers, but which may safely be classed amongst the "might-have-beens." To our mind it seems really a waste of time to spend even a single hour upon working out such devices so long as the simple third rail and overhead trolley wire systems remain feasible for ordinary working conditions.

The first of the devices under notice claims to be especially suitable for elevated and suburban railways usually worked by steam. It consists of a sectional third rail with alternating live and dead portions, the mechanism for throwing over the switch contact arrangement (sending current into each live section) being actuated by frictional end pressure due to the contact shoe upon each separate section of the third rail, which has a slight amount of end play.

The only advantage of such a device is that the current is kept from an exposed rail conductor except on such portions as are covered by the car or train, and presumably this is considered to be worth the extra cost and complication of the system. But the only persons to consider (in this country at least), so far as freedom from shock is concerned, are the railroad employés who are naturally supposed to know the dangers of their work and take precautions accordingly. There is no great economy of current in keeping it within a feeder, save only on the portions of line under the trains themselves: usually the third rail itself is feeder and conductor rolled into one.

The working details of the device are, however, developed in a most ingenious way, and make one wonder what the inventor might not do if he were to attempt a contrivance on absolutely new lines.

The other device is also characterised by novelty and ingenuity. It is intended for use with a third rail in street tramway work, and embodies the use of a small set of storage batteries and a motor generator on the car of sufficient size (but obviously quite small) to actuate the magnetic switches generally employed for throwing current into the third rail sections, one after the other. This motor generator is wound to take a small current from the battery at 10 volts and convert it into a 500-volt current, so that the third rail and rail return may be introduced directly into the magnetic switch circuit.

The third rail sections are alternately live and dead, the former as a rule about 8 feet long, the latter 6 feet. With two shoes upon each car there is always one live section in circuit.

This device may also be considered well worked out in detail, but the surface contact system for street tramways has, in any case, but little chance of general adoption, even in the towns and cities of this country where some amount of prejudice exists against overhead wires.

STEAM ENGINE MECHANICAL EFFICIENCY.

A correspondence is going on in *Engineering* anent an expression of opinion by Mr. Raworth that there would be a loss of only 15 per cent. between indicated and electrical horse-power in a cotton mill, as compared with a loss of 40 per cent. between cylinder and crank-shaft in the present arrangement. Mr. Herschmann corrects the writer, and points out that Mr. Raworth's figures had reference to the waste between the cylinder and the driven shafts of the machines. Nevertheless he is sceptical of Mr. Raworth's 15 per cent. for electricity. This correspondent rightly states that the cotton spinner is in a position to use large engines of an economical kind, and that in cotton mill driving, power is taken fairly direct to machinery, and that machinery may be classed as grouped, and properly looked upon as suitable for driving from shafting. The speed of motors also is too high for direct connection to machine shafts, and generally it is concluded that cotton mill driving does not afford the best field for electricity.

There is a good deal in what this correspondent says. A cotton mill is not a large cube through which a horse-power of 1,000 or 1,200 indicated is required to be distributed. Driving is very direct from the engine fly-wheel to the line-shafts. As compared with the losses in the ropes and shafts, there would be the loss at the dynamo, in the leads, and at the motors, and it is not as though there were any particularly long pieces of shafting. It is certain that at present a mill-owner would think twice before buying electricity; he might make his own, and use electrical transmission. But in a cotton mill there is never a considerable percentage of machinery standing idle. Almost everything in a cotton mill is paid for at piece rates, and while machinery is largely self-stopping, the attendants are particularly quick to set them going again when the "ends" are pieced up. Even supposing that electricity could be cheaply purchased, there remains the question of heating. Throughout the year some heating is necessary, or may be any morning. In winter it is a *sine quâ non*.

There must be steam boilers for this alone, and this fact would always help out the generation of power on the spot. The importance of reducing frictional losses to a minimum is rendered very evident in cotton mill practice. The product of a cotton mill contains very little energy—at most that represented by the torsion put upon the fibres twisted at an exceedingly small moment of resistance. A large mill probably turns out about 1,000,000 miles of single yarn every week, containing about 1,250,000 millions of twists, which has been estimated to require, at the outside, 60 foot pounds of work per minute, or about $\frac{1}{500}$th of a horse-power. To secure this small end demands, say, 1,200 indicated horse-power, all of which disappears as friction and reappears as heat. A running mill soon warms itself to an intolerable degree in summer-time, and windows are opened.

There are those who probably hope to see electrical motors still more sub-divided than as at present. The ultimate divisibility would come in where every spindle had its own little motor; but it is not in the spindle driving that power is lost: it is in revolving the several rows of heavily weighted rollers, badly lubricated, that power is absorbed, to an extent compared with which the few lines of well-attended shafting are a small item.

As in most machinery, not much is known as to the power requisite to turn cotton machinery. The total work per spindle may be known, but we cannot learn of a roving frame being dynamometered when running complete and also with the rollers at rest, or of a spinning frame being measured for power absorbtion when run empty and when full. The difference goes into the drawing and twisting of the yarn, and is a mere nothing.

But to return to Mr. Herschmann, if the cotton spinner can himself generate a horse-power for 2 lbs. of coal, he becomes a difficult customer to deal with by an electrical company, even if this company generate with only 1½ lbs. of fuel. For electrical driving of factories the cotton mill, in fact, is one of the worst cases to deal with, and the large and widely-scattered workshops and tools of the ship yard or engineers' shop with occasionally worked heavy tools, stand as examples favourable to electricity.

THE BURNING QUESTION.

Our article under this heading on February 4th, concluded with the remark that we considered the cost of labour per ton of refuse burned, in relation to the wages paid, and the number of hours worked by the men, the most important element in the destructor question. This by no means removes the necessity of fulfilling the other conditions which we mentioned, viz., that nuisance from dust or smoke must not occur, that the refuse should be completely burned, and that the temperature should be maintained as high as possible. But as we laid such stress upon cost, we considered it our duty to make some further inquiries upon this subject; and we have received the most courteous replies from the engineers of whom we sought information.

In view of the letter from Mr. Jones, C.E., of Ealing, which also appeared in our issue of February 4th, our first desire was to compare the cost of the systems of destroying refuse and sludge mixed at Ealing and at Leyton.

Mr. Jones resented warmly the statement made in a non-technical contemporary, which has been repeated in many other journals, that the Leyton destructor was the first to deal successfully with sewage sludge, and we confess we sympathise with him. It is hard to hear such statements made after one has had a destructor doing that very thing for 15 years. Mr. Dawson, C.E., of Leyton, is kind enough to point out to us that his sludge is first pressed, whereas Mr. Jones's is unpressed.

We quite admit that pressing gives the stuff a soap-like consistency, and that it may be harder to burn pressed than unpressed; but, if so, why press it? We find that burning it unpressed is, from the point of view of cost, wholly in Mr. Jones's favour.

Mr. Dawson informs us that the cost of burning the refuse and sludge at Leyton works out to 1s. 7d. per ton for some months past, though taking only the last month it is 1s. 6½d.

To consider first the sludge alone.

We will assume that the cost of pressing is 6d. per ton of *wet sludge*. This we know to be a low estimate. The cost of burning is 1s. 6½d. per ton of *pressed* sludge. Assuming that one-third of the weight of wet sludge has been removed by pressing, this would amount to, say, 1s. per ton of *wet* sludge.

The total cost is, therefore, 1s. 6d. per ton of wet sludge for pressing and burning.

On the other hand, Mr. Jones states his cost at 1s. 1½d. per ton burned, exclusive of returns in the shape of sale of of clinker, &c.

Mr. Jones's 15 years' practice, therefore, appears to come out, as regards cost, superior to the "new departure" at Leyton. We make these remarks in the hope of eliciting further information in the comparison of the two systems.

At the same time, we do not profess to admire the low temperature system of destructors, and we believe that modern forced draught furnaces would, in Mr. Jones's hands, further secure his historical pre-eminence in sludge burning.

But if we are to pursue this question of sludge still further, what are we to say of Sir Douglas Galton's startling statement at Leyton in reference to the London sludge fleet?

We have now had an opportunity of studying his remarks at leisure in the *Leyton Express and Independent* of January 29th, which modestly refers to the destructor, in a leading article, as "*the pride of Leyton*."

Sir Douglas Galton is reported to have said:—"In the metropolis a charge of above £100,000 a year is incurred to get rid of it [the sludge] by putting it into barges, from which it is dropped into the sea. That, I must confess, seems to me a wasteful process. . . . .

"Here, at Leyton, with the assistance of Messrs. Beaman and Deas, you have done much better than London now does. You have obtained a destructor which deals in a marvellous way with the refuse sludge. You avoid the cost of barging, for after removing it from your tanks, you have only to squeeze it thoroughly, and throw it into furnaces, and then the heat from its perfect combustion assists in working the necessary machinery."

Now we have seen that the cost of pressing and burning the sludge is about 1s. 6d. per ton of wet sludge at Leyton. We obtained from the London County Council the report of their able chief engineer, Sir Alexander Binnie, on the treatment of London sewage during 1896, this being the latest report for a complete year which was available to us.

We must say that Sir Alexander Binnie has no need of any champion to defend the system inaugurated by his distinguished predecessor, and improved by himself, for we have never read a more interesting, exact, comprehensive and satisfactory statement upon any branch of municipal business than this report.

We find from it that no less than 2,178,000 tons of sludge, containing 91·08 per cent. to 91·44 per cent. of moisture, were sent to sea in that year. The average cost of conveying this enormous mass of offensive matter 50 miles out was 3·4 pence per ton for working expenses, or 4·59 pence per ton inclusive of capital and all other charges. In view of these figures, does Sir Douglas Galton seriously advocate a substitution of the Leyton process for that now in operation at Barking and Crossness?

To put it at the lowest figure, we think London will object to paying an extra charge of 1s. 1d. per ton of sludge, or, in other words, £118,000 per annum, over and above the present cost, which is £41,654.

Allowances should be made for Sir Douglas Galton, as he was the "lion" of the occasion; and, presumably, his remarks were intended for a popular audience; but lions should be careful how they roar, particularly when they are well-known scientific authorities.

To return to the question of cost per ton burned for refuse in general, we have before us a report from which it appears that at the "Lero" destructor at Leicester, which is on the natural draught, low temperature system, under the management of the designer and patentee, Mr. Biddles, there were burned, in 1896, 12,956 tons of ashpit refuse; 373 tons of trade refuse; 147 tons of fish offal; and 267 mattresses. The total wages paid to firemen were £328.

We exclude the wages paid for repairs, mortar grinding, weighing in, and rat-catching, as we believe these items are not usually reckoned in the cost per ton burned.

The cost of labour per ton burned is, therefore, according to this statement kindly furnished to us by Mr. Biddles, under 6d. per ton.

From an interesting paper by Mr. George Darley, superintendent of the cleansing department at Leeds, published on January 29th last, in our esteemed contemporary, the *Public Health Engineer*, we learn that the cost of labour at the destructor at Meanwood, Leeds, is 7½d. per ton, while we are informed that at Bradford, Hammerton Street, it is 7d. per ton. The two last mentioned destructors are on the Horsfall system, and are worked at high temperatures under forced draught.

These figures show that the cost of labour at Leyton of 1s. 6½d. per ton burned is susceptible of very great improvement. It must not be forgotten that sludge is being burned at Leyton; but we think that the weighty nature of the sludge, and the fact that 60 per cent. of it is water, and requires only to be evaporated, more than compensates for its damping effect on the fires.

Moreover, other authorities have carried out tests at Leyton on refuse only, without sludge, and the costs published tend to confirm our opinion.

We look forward to the time when, at every important destructor, the costs will be kept and tabulated as carefully and completely as those relating to the disposal of the London sludge; or to name an example more familiar to our readers, the works' costs of practically every electricity station in the country.

ELECTRICAL NEWS FROM AUSTRALIA.

[FROM OUR SPECIAL CORRESPONDENT AT SYDNEY.]

Australia has, unfortunately, recently added two more to the list of electrically caused deaths. On Sunday, September 11th, a lad named Richard Trusswell, aged 17 years, residing at Armadale, a suburb of Melbourne, challenged two companions to climb to the top of an electric light pole in Stanhope Street, Malvern, in less time than he could. The challenge being accepted, Trusswell quickly ascended the pole, and caught the wire with both hands, and almost immediately fell to the ground insensible. Medical aid was quickly summoned, but death had evidently been instantaneous. The lad's hands were terribly burnt, and one finger was burnt off at the joint. According to the evidence of his companions, sparks flew from his hands when he caught the wire, his legs came off the post, and after swaying a second or two he fell. He made no exclamation when he came in contact with the wire, but when, black in the face, he fell to the ground, he groaned once or twice, and then expired. The wire, which was insulated, was the property of the New Australian Electric Company.

The second instance occurred in Brisbane. On November 3rd, a man named Fox, foreman in charge of a gang doing repair work on the trolley line, received a shock and fell from the top of a waggon platform, and died within a few minutes, before medical aid could be summoned. The medical evidence showed that his skull was fractured, but it did not appear to be clear as to the exact cause of death: whether it was the shock, the fall, or both combined. There was no rail round the platform, and though rubber gloves appear to have been served out, they were not used. The men started work at 5.30, before current was turned on, and the accident happened immediately after 6.30, at which time current was turned on as usual for the first train to take up the regular running.

In connection with the various electric tram lines in Sydney, several contracts have been let, principally in connection with the George Street line. Tenders were called for the construction of permanent way and erection of poles in two sections, one going to J. McSweeney at £12,754, and the other to Wilmot & Morgan at £25,690, the highest tenders being respectively £18,118 and £31,820, 10 tenders being received for each; the contract for car house entrance going to H. W. Peabody for £1,200, as did also the construction of the crossing of the cable tram in King Street for £268. Messrs. G. & C. Hoskins are constructing the boilers locally, their accepted tender being for the sum of £4,718. The excavations for the power house at the back of Harris Street will cost £886, and is being carried out by C. McClure. Messrs. Noyes Bros., agents for Callender and Co., have secured the contract for the supply of feeder cables and junction boxes at schedule rates (about £7,540) for the George Street line, and also for the Rose Bay line at £459. The generators for the latter line are still lying outside the cable power house, but it is expected that they will be put in place before the end of the year, and the outside construction work will be commenced shortly. The estimated cost is £13,225. As before stated, Messrs. H. H. Kingsbury and Co., agents for the General Electric Company of U.S.A., are supplying generators for both lines.

The method adopted by the Goulburn (N.S.W.) Borough Council on entering into the question of electrically lighting the town has ended in a *fiasco*. As I mentioned in a former letter, the Council employed a consulting engineer, at an absurdly low fee, to draw up a "general specification," upon which tenders were called, with the result that so little being specified, a meeting of the electrical trades was held in Sydney to protest against the vagueness of the details supplied. First the consulting engineer was asked to give some more definite details of his requirements, and on his failing to accede, recourse was had to the Goulburn Council, who expressed themselves as highly indignant at being called upon to go to the expense of providing information, and one alderman, in defending the specification, said "the complaint came from a ring who desired the Council to expend money on information they should procure themselves." The majority of the aldermen defended the specification, "as the responsibility thrown on the tenders is a great saving to the Council." Out of the dozen or more firms who might have tendered, only two sent in.

The specification commences with a preamble to the following effect: "This specification is prepared with a view to enable electric light contractors to submit tenders to the Municipal Council of Goulburn, for the lighting of that city, on equal terms with one another, while leaving them entirely free to select those special classes of machinery and fittings which they represent or prefer. Contractors must understand that there is no intention of expressing any preference for particular types of boilers, engines, dynamos, conductors, or lamps, but they are to take the following particulars rather as statements of the conditions which they are to fulfil, and the basis on which rival tenders will be compared, &c." A map was provided, showing public lighting and the street frontages where provision is to be made for private lighting. A schedule of arc and incandescent lamps is then given, with the amount of watts required, the total being given as *66,000 watts*. Immediately below this comes the following delightfully ingenuous statement: "If the whole of the contract current of *80 kilowatts* is to be delivered from one dynamo, or if that portion of it required for the incandescent lights is to be supplied from one machine, and that for the arc lighting from another one of a different character; then there will require to be a complete duplication of the generating plant, altogether making the dynamos equal to a total of *160 kilowatts;* but should the contractor propose to supply both the arc and incandescent lights from two similar machines equal to 40,000 watts each, then a triplicate machine making a total possible output of 120 kilowatts will be sufficient as a reserve."

Not content with giving so many alternatives in the matter of generators, additional choice is given in the matter of sites, two being available at a considerable distance apart, and as one site is near the water works, with water handy for condensing purposes, the question of condensing or non-condensing engines is left for the poor unfortunate contractor to put in an alternative tender for. The power house is left entirely to the contractor's imagination and architectural ideas. In the matter of boilers the contractor is once again given a free hand. "Contractors will be at liberty to tender on either the 'internal fired,' 'water tube,' or 'multitubular' systems; and the matter of spare boiler power is arranged on the same plan as is adopted in the case of the dynamos, the contractors being permitted to put in two, three, or any other number they consider advisable;" the clause relating to boilers finishes as follows: "Although not here expressed in detail, it is to be understood that the most modern system of construction and highest class of workmanship is to be stipulated for by tenderers." In the clause relating to boiler-mountings, the following phrases occur: "The front fittings and doors are to be of handsome get up." . . . "One spare set of fire-bars *had better* be included, and two sets of fire tools." In referring to steam pipes also the phrase occurs: "These pipes *had better* be of copper." The specification is also very open-minded on the subject of steam engines. "The engines are to be of compound type, either open or closed, and may be connected to the dynamo direct or by belts. Contractors who propose to drive smaller dynamos at a higher speed by belts must set against the saving in the cost of the dynamos the extra cost of the larger building required, &c." (What does this mean?) In dealing with the switchboard, superlative wisdom is shown in the remark that "The character of the switchboard will as greatly depend upon the nature of the scheme, that absolute requirements cannot be set forth." Why, certainly! Contractors are required to supply and fix all transformers, if any, that may be required; but apparently they are at liberty to state how many will be necessary, and the sizes of same. No mains are shown on plan, but they must be provided, and must have an insulation resistance of 600 megohms per mile "when coiled on the ground," and "the sections are to be so proportioned, that when carrying the full load, the fall of potential shall not be more than $2\frac{1}{2}$ per cent. in either primary or secondary mains." (This latter information seems to show that the consulting engineer has a hitherto carefully concealed preference for alternating currents.) Coming to poles, the contractor is given another opportunity for diversion, by providing the option of galvanised tubular poles at the centres of street intersections, or iron brackets from the corners of buildings; and further, is permitted the choice of overhead or underground conductors, with the further advantage of a solid or draw-in system for the latter.

Towards the end a suggestion is airily thrown out that, after all, perhaps a continuous current transformer system might be preferred, and this is made further use of to perplex the already addled tender with its bearing on the use of open or closed arc lamps. At a low computation there would be no difficulty in sending in a hundred alternative tenders, all of which would comply with the specification. What a fortunate thing it is for the consulting engineer that only two firms have tendered, and that each have sent in only six alternative tenders for him to consider the merits of.

The Corporation of Port Adelaide (S.A.) have saved themselves all this bother by coming to terms with Mr. W. W. Crawfurd, agent for Messrs. Johnson & Phillips, who is undertaking the lighting of the town on the three-wire system with Johnson and Phillips' dynamos direct coupled to Belliss engines with a reserve of accumulators. It is understood that this work is being carried out by the same syndicate that is endeavouring to get a Bill through the South Australian Legislative Assembly with the object of lighting the City of Adelaide; the Bill is being strenuously opposed by the Adelaide Council in the belief, as they expressed it, "that the promoters were not a *bona fide* company anxious to carry out the electric work themselves, but rather a grasping syndicate wishful to secure electric rights for speculative purposes." The company, however, answered this by promptly offering to deposit £2,000 if the City Corporation would give them a contract for lighting Adelaide. In an examination in connection with this Bill the town clerk stated that the Corporation were paying between £4,600 and £4,700 per annum for 992 gas lamps. At Port Adelaide 130 gas lamps are being replaced by 24 arc lamps and 66 50-C.P. incandescents.

The question of private lighting was discussed at the meeting of the Melbourne City Council lately. A report was received from the Public Works Committee stating that Government sanction to the supply of light for public and private purposes by the Corporation had been secured, and recommending that advantage should be taken of the privilege. At charges of 5d. per unit for incandescent lamps, and £25 to £19 per annum each for arc lamps (according to the time they were kept alight) the present plant of the Council should give a revenue, when fully employed, of £5,295, besides supplying certain corporation buildings. Deducting the working expenses and other charges, this, the committee estimated, should leave a profit of £1,200. Many applications for the supply of electricity to private premises had been received, some of which were very urgent, and were being supplied. In the discussion which followed, several of the aldermen counselled delay, averring that unless the electric light improved considerably, it would be superseded by the Welsbach gas light. This idea was scouted by others, and ultimately the committee's report and suggestions were adopted.

Mr. Hesketh, the Queensland Government's electrical engineer, in reporting on the proposed electric lighting of Brisbane, states that he thinks electric lighting a proper and remunerative undertaking for the Corporation, and recommends that at first operations should be confined to the main streets of the city, using the direct-current system, with a three-wire distribution at 400 volts.

The first long distance telephone line in New South Wales, between Sydney and Newcastle, is almost completed. The connection is made by means of a cable passing through the telephone tunnel recently constructed in Pitt Street, thence into George Street North, joining the Harbour Cable at Dawes Point Battery to meet the overland line. The total length of line is close on 100 miles, and the tariff is to be 3s. for a three-minutes' conversation.

THE MEASUREMENT OF FAULT RESISTANCES WITH A VOLTMETER.

By STUART A. RUSSELL.

THE first proposal to use a voltmeter for the measurement of the fault resistance of an electric circuit without interrupting the service dates back many years; but when it was first proposed, the conditions necessary to obtain a correct result were not properly understood, and even as late as 1889, it was stated in a paper read at the Institution of Electrical Engineers that if a voltmeter was connected from one conductor to earth, the total leakage current could be calculated by dividing the voltmeter reading in volts by the resistance of the instrument. In the discussion it was pointed out that such a method could not give correct results, but no description of the proper way of using the voltmeter was given by any of the speakers.

Although the correct method of measuring fault resistances with a voltmeter was published about this time, and must be well known to many readers of the ELECTRICAL REVIEW, improper or incomplete methods are still frequently used, and the full amount of information that may be derived from a voltmeter test does not appear to be generally known. It is proposed, therefore, in this article to describe several applications of the use of the voltmeter and to draw attention to the results that may be obtained.

Two-wire Circuit.—In fig. 1 let A and B be the positive

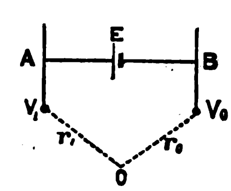

FIG. 1.

and negative conductors of a circuit having a difference of potential between them of E volts.

Let O be the earth taken at zero potential.

Let r_1 and r_0 be the fault resistances of A and B, and F be their combined resistance so that $\frac{1}{F} = \frac{1}{r_1} + \frac{1}{r_0}$.

Connect A to earth by a voltmeter of resistance G, and note the potential, V_1, of the conductor; then connect B to earth by the same voltmeter and note the potential, V_0, of B (which will be a negative quantity), and finally connect A and B and note the difference of potential, E.

$$\text{Then } \frac{V_1}{r_1} + \frac{V_1}{G} + \frac{V_1 - E}{r_0} = 0, \text{ or } V_1\left(\frac{1}{F} + \frac{1}{G}\right) = \frac{E}{r_0}, \quad (1)$$

$$\text{and } \frac{V_0}{r_0} + \frac{V_0}{G} + \frac{V_0 + E}{r_1} = 0, \text{ or } V_0\left(\frac{1}{F} + \frac{1}{G}\right) = -\frac{}{r_1}. \quad (2)$$

By subtracting (2) from (1) we get $(V_1 - V_0)\left(\frac{1}{F}+\frac{1}{G}\right)=\frac{E}{F}$,

$$\text{whence } F = G\,\frac{E-(V_1-V_0)}{V_1-V_0}. \qquad (3)$$

From (1) and (2) we also see that $\frac{V_1}{r_1} = -\frac{V_0}{r_0}$ and by substituting this value of $\frac{V_1}{r_1}$ in (1) we get

$$-\frac{V_0}{r_0}+\frac{V_1}{G}+\frac{V_1-E}{r_0}=0, \text{ whence } r_0 = G\,\frac{E-(V_1-V_0)}{V_1},$$

and in similar manner from (2) we get $r_1 = G\,\frac{E-(V_1-V_0)}{-V_0}$.

It must be noted that if the voltmeter readings V_1 and V_0 are used without regard to the direction of the current through the instrument, the sign of V_0 must be changed in these equations as V_0 itself is a negative quantity; the equation for the combined resistance becoming

$$F = G\,\frac{E-(V_1+V_0)}{V_1+V_0},$$

whilst $r_0 = G\,\frac{E-(V_1+V_0)}{V_1}$ and $r_1 = G\,\frac{E-(V_1+V_0)}{V_0}$.

As the Board of Trade Regulations stipulate that the leakage current shall not be more than $\frac{1}{1000}$th of the maximum supply current, and as other regulations fix the maximum permissible ratio of leakage current to supply current, it is desirable that the value of the leakage current, c, should be known, and we see from the above equations that

$$c = \frac{E}{r_1+r_0} = \frac{-E\,V_1\,V_0}{G\,(V_1-V_0)\,\{E-(V_1-V_0)\}}.$$

When using a voltmeter in this manner the best results are obtained if its resistance is about equal to the combined fault resistance, that is when $V_1 - V_0 = \frac{E}{2}$. If the resistance of the voltmeter is much less than that of the fault, the readings are too low down on the scale where the calibration of most instruments is least accurate; whilst if the resistance of the voltmeter is very high compared with that of the fault, $V_1 - V_0$ is so nearly equal to E that a small percentage error in the values of E or of $V_1 - V_0$ causes a large percentage error in $E - (V_1 - V_0)$ which is the numerator in the equations. A convenient plan is to have the voltmeter fitted with one or two shunts which can be used as required to get suitable readings; the value of G used in the equations being, of course, the resistance of the shunted voltmeter.

If an electrostatic voltmeter, or one of very high resistance only is available, a resistance coil of known value, S, should be obtained and the test can then be made in the following manner: connect one conductor to earth by the voltmeter and note the reading, V, then shunt the voltmeter by the resistance, S, and note the reading V′. If the voltmeter is connected between A and earth (fig. 1), and we suppose the value of G so high that $\frac{1}{G}$ is negligible, we have

$$\frac{V}{r_1}+\frac{V-E}{r_0}=0, \text{ or } \frac{V}{F}-\frac{E}{r_0}=0, \qquad (4)$$

and when the shunt S is also connected between A and earth, we have

$$\frac{V'}{r_1}+\frac{V'}{S}+\frac{V'-E}{r_0}=0, \text{ or } \frac{V'}{F}+\frac{V'}{S}-\frac{E}{r_0}=0. \qquad (5)$$

From these two equations we get

$$\frac{V-V'}{F}-\frac{V'}{S}=0, \text{ or } F=\frac{S\,(V-V')}{V'}. \qquad (6)$$

The values of r_0 and r_1 can be obtained separately by substituting in the equation $\frac{V}{F}-\frac{E}{r_0}=0$, the value just obtained for F, which gives

$$r_0 = \frac{E\,S\,(V-V')}{V\,V'},$$

and since from equation (4) we know that

$$r_1 = r_0\,\frac{V}{E-V},$$

we get

$$r_1 = \frac{E\,S\,(V-V')}{V'\,(E-V)}.$$

The leakage current $c = \frac{E}{r_1+r_0} = \frac{V\,V'\,(E-V)}{E\,S\,(V-V')}$.

Three-wire System.—Similar methods of determining the value of F may be used on a three-wire system, but under ordinary working conditions the separate values of the fault resistances of each conductor cannot be fixed. It is, however, possible to determine the minimum values that these fault resistances can have, and the maximum leakage current to earth that can exist under the conditions observed at the time of the test; and, further, by a modification of the conditions of testing, the actual values of the separate fault resistances can be determined.

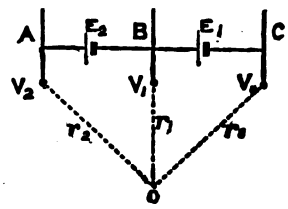

Fig. 2.

Let A, B, and C, be the three conductors, E_2 and E_1 the potential differences between A and B and between B and C, r_2, r_1, and r_0, the fault resistances of positive, neutral, and negative conductors, and F their combined resistance.

Connect A to earth by a voltmeter of resistance G and note the potential V_2 of the conductor, then connect C to earth by the same voltmeter, noting the potential V_0 of the conductor and finally measure E_2 and E_1.

$$\text{Then } \frac{V_2}{r_2}+\frac{V_2}{G}+\frac{V_2-E_2}{r_1}+\frac{V_2-E_2-E_1}{r_0}=0,$$

$$\text{or } V_2\left(\frac{1}{F}+\frac{1}{G}\right)-\frac{E_2}{r_1}-\frac{E_2+E_1}{r_0}=0. \qquad (7)$$

$$\text{and } \frac{V_0}{r_0}+\frac{V_0}{G}+\frac{V_0+E_1}{r_1}+\frac{V_0+E_2+E_1}{r_2}=0,$$

$$\text{or } V_0\left(\frac{1}{F}+\frac{1}{G}\right)+\frac{E_1}{r_1}+\frac{E_2+E_1}{r_2}=0. \qquad (8)$$

From these two equations we get

$$(V_2-V_0)\left(\frac{1}{F}+\frac{1}{G}\right)-\frac{E_2+E_1}{F}=0,$$

$$\text{whence } F = G\,\frac{E_2+E_1-(V_2-V_0)}{V_2-V_0} = E, \text{ or if } E_2 = E_1 \qquad (9)$$

$$F = G\,\frac{2\,E-(V_2-V_0)}{V_2-V_0}.$$

It must again be noted that as the potential V_0 of C is negative, $V_2 - V_0$ is equal to the sum of the voltmeter readings, if these latter are used without regard to the direction of the current through the instrument.

From these equations it is not possible to determine the separate values of r_2, r_1 and r_0; but if the values of E_2 and E_1 can be varied, we can get two equations containing only two of the three unknown quantities. This method was first suggested to the author by Prof. Rousseau, of the Brussels University; the test being made at the time of minimum output by first making the ratio, $\frac{E_1}{E_2} = K$, as large as possible, and then repeating the measurements, after having changed the pressures so that $\frac{e_1}{e_2} = k$ is as small as possible. From the first set of measurements we can determine the value of F, as shown above, and we also get equation (7), which can be written

$$\frac{V_2}{E_2}\left(\frac{1}{F}+\frac{1}{G}\right)=\frac{1}{r_1}+\frac{1+K}{r_0}. \qquad (10)$$

If now we change the pressures between the conductors and measure e_2, e_1 and v_2, we have

$$\frac{v_2}{e_2}\left(\frac{1}{F}+\frac{1}{G}\right)=\frac{1}{r_1}+\frac{1+k}{r_0}. \qquad (11)$$

Subtracting (11) from (10) we have

$$\left(\frac{V_2}{E_2}-\frac{v_2}{e_2}\right)\left(\frac{1}{F}+\frac{1}{G}\right)=\frac{K-k}{r_0}$$

or $r_0=\dfrac{E_2\,e_2\,(K-k)}{(e_2\,V_2-E_2\,v_2)\left(\frac{1}{F}+\frac{1}{G}\right)}$. By substituting this value of r_0 in equation (10) we can get the value of r_1; and r_2 can then be calculated from $\frac{1}{r_2}=\frac{1}{F}-\frac{1}{r_1}-\frac{1}{r_0}$.

If it is not convenient to vary the values of E_2 and E_1, it is still possible to determine the minimum values which any of the three resistances can have, and also the maximum leakage current to earth.

We know from (7) and (8) that

$$V_2\left(\frac{1}{F}+\frac{1}{G}\right)=\frac{E_2}{r_1}+\frac{E_2+E_1}{r_0}$$

and

$$-V_0\left(\frac{1}{F}+\frac{1}{G}\right)=\frac{E_1}{r_1}+\frac{E_2+E_1}{r_2}$$

From these equations we see that r_2 and r_0 will have their minimum values when $\frac{E_1}{r_1}$ and $\frac{E_2}{r_1}=0$, *i.e.*, when $r_1=\infty$; and, similarly, r_1 will be a minimum when either r_0 or r_2 is infinite. We, therefore, get the following values:—

$$r_2\text{ min.}=\frac{E_2+E_1}{-V_0\left(\frac{1}{F}+\frac{1}{G}\right)}=\frac{F\,(V_2-V_0)}{-V_0}=\frac{G\,\{E_2+E_1-(V_2-V_0)\}}{-V_0}$$

$$r_1\text{ min.}=\frac{E_2}{V_2\left(\frac{1}{F}+\frac{1}{G}\right)}=\frac{E_2\,F\,(V_2-V_0)}{V_2\,(E_2+E_1)}=\frac{G\,E_2\,\{E_2+E_1-(V_2-V_0)\}}{V_2\,(E_2+E_1)}$$

$$\text{or}\quad=\frac{E_1}{-V_0\left(\frac{1}{F}+\frac{1}{G}\right)}=\frac{E_1\,F\,(V_2-V_0)}{-V_0\,(E_2+E_1)}=\frac{G\,E_1\,\{E_2+E_1-(V_2-V_0)\}}{-V_0\,(E_2+E_1)}$$

according to whether V_2 is numerically smaller or greater than V_0,

$$r_0\text{ min.}=\frac{E_2+E_1}{V_2\left(\frac{1}{F}+\frac{1}{G}\right)}=\frac{F\,(V_2-V_0)}{V_2}=\frac{G\,\{E_2+E_1-(V_2-V_0)\}}{V_2}$$

The maximum leakage current to earth will occur when r_2 or r_0 is a minimum, that is, when $r_1=\infty$ and is equal to

$$\frac{E_2+E_1}{r_2+r_0}=\frac{E_2+E_1}{F\,(V_2-V_0)\left(\frac{1}{V_2}-\frac{1}{V_0}\right)}=\frac{-V_2\,V_0\,(E_2+E_1)}{F\,(V_2-V_0)^2}$$

If an electrostatic or high resistance voltmeter is employed to make the test, one conductor, say A, is first connected to earth through the voltmeter, and the reading, V, is noted; and then the shunt, S, is also connected between A and the earth, and the reading, V′ is noted. We then have

$$\frac{V}{r_2}+\frac{V-E_2}{r_1}+\frac{V-(E_2+E_1)}{r_0}=0,\text{ or }\frac{V}{F}-\frac{E_2}{r_1}-\frac{E_2+E_1}{r_0}=0 \qquad (12)$$

and

$$\frac{V'}{S}+\frac{V'}{r_2}+\frac{V'-E_2}{r_1}+\frac{V'-(E_2+E_1)}{r_0}=0,$$

or

$$\frac{V'}{F}+\frac{V'}{S}-\frac{E_2}{r_1}-\frac{E_2+E_1}{r_0}=0; \qquad (13)$$

whence

$$\frac{V-V'}{F}-\frac{V'}{S}=0,\text{ or }F=\frac{S\,(V-V')}{V'}. \qquad (14)$$

By assigning, as before, different values to the ratio $\frac{E_1}{E_2}$, the values of r_2, r_1, and r_0 can be calculated, since we get

$$\frac{V}{F\,E_2}=\frac{1}{r_1}+\frac{1+K}{r_0}\text{ and }\frac{v}{F\,e_2}=\frac{1}{r_1}+\frac{1+k}{r_0},$$

whence

$$\frac{1}{F}\left(\frac{V}{E_2}-\frac{v}{e_2}\right)=\frac{K-k}{r_0}\text{ or }r_0=\frac{F\,E_2\,e_2\,(K-k)}{e_2\,V-E_2\,v}.$$

When the values of E_2 and E_1 cannot be varied the minimum values of r_2, r_1, and r_0, and the maximum leakage current can be calculated as follows:—We have from (12) and (14)

$$\frac{E_2}{r_1}+\frac{E_2+E_1}{r_0}=\frac{V}{F}=\frac{V\,V'}{S\,(V-V')},$$

from which we see that

$$r_0\text{ min.}=\frac{(E_2+E_1)\,(V-V')\,S}{V\,V'}\text{ when }r_1=\infty,$$

and

$$r_1\text{ min.}=\frac{E_2\,(V-V')\,S}{V\,V'}\text{ when }r_0=\infty.$$

The equation (12) may also be written

$$\frac{E_1}{r_1}+\frac{E_2+E_1}{r_2}=\frac{E_2+E_1-V}{F}=\frac{V'\,(E_2+E_1-V)}{S\,(V-V')}$$

from which we see that

$$r_2\text{ min.}=\frac{(E_2+E_1)\,(V-V')\,S}{V'\,(E_2+E_1-V)}\text{ when }r_1=\infty,$$

and

$$r_1\text{ min.}=\frac{E_1\,(V-V')\,S}{V'\,(E_2+E_1-V)}\text{ when }r_2=\infty.$$

The maximum leakage current to earth will occur when r_2 and r_0 have their minimum values and $r_1=\infty$, so that

$$e=\frac{E_2+E_1}{r_2+r_0}=\frac{V\,V'\,(E_2+E_1-V)}{(E_2+E_1)\,(V-V')\,S}.$$

Either of the voltmeter methods described above can, as we have indicated, be made to give very valuable information concerning the condition of the mains; and as the tests require very little apparatus and are easily and rapidly made, it is somewhat surprising that so few central stations should be provided with fault measuring instruments as part of the ordinary switchboard equipment. The author has found the high resistance voltmeter method the more convenient in practice, and has used it in conjunction with a high resistance registering voltmeter permanently connected between one main and earth: the continuous record of the variations of earth potential coupled with the results of periodic measurements of V and V′, forming a fairly complete record of the condition of the mains.

The fault resistances measured by the above methods are those of the complete circuit, including dynamos, batteries, mains, and house circuits; and if it is desired to measure the resistance of a part of the circuit, it is necessary to isolate that part from the remainder and measure its fault resistance in some other way. This may be done with a portable testing set and battery or magneto, but by a slight modification of method, the fault resistance of a house circuit, or of any section of the circuit that can be isolated for a minute or two from the remainder, can be measured by the voltmeter using the street mains to supply the testing pressure, and thus doing away with the necessity for a special testing set and battery or magneto.

In fig. 3 let A and B be the conductors of a two-wire main, having a difference of potential, E, between them; and

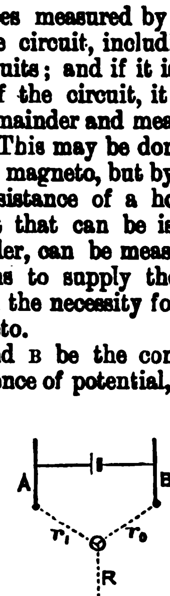

FIG. 3.

let D be a terminal, to which are connected the conductors of the house circuit or other section of the mains whose fault resistance R is to be measured, it being understood that the section under test is disconnected entirely from the live mains. Using the same notation as before, we have, when the voltmeter is connected between A and O, from equation (1)

$$\frac{E}{r_0}=\frac{V_1\,(F+G)}{F\,G},$$

and when connected between A and D,

$$\frac{E}{r_0}=v_1\left(\frac{1}{F}+\frac{1}{G+R}\right)=v_1\left\{\frac{F+G+R}{F\,(G+R)}\right\}=v\left(\frac{F+G+R}{F\,G}\right)$$

if v is the voltmeter reading and v_1 the potential of A under these last conditions. From these equations we get

$$V_1 (F+G) = v (F+G+R) \text{ or } R = \frac{(V_1 - v)(F+G)}{v} = \frac{(V_1 - v) G E}{v (V_1 - V_0)}$$

If an electrostatic or high resistance voltmeter is employed, A and D are connected by a resistance S, and the potential differences V between A and O, and V′ between A and D, are measured, then

$$\frac{V}{S+R} = \frac{V'}{S} \text{ or } R = \frac{S(V - V')}{V'}.$$

In this latter case the same result is obtained if the mains are on the three-wire system, and in the former case we have from (7)

$$\frac{E_2}{r_1} + \frac{E_2 + E_1}{r_0} = \frac{V_2 (F+G)}{F G},$$

and

$$\frac{E_2}{r_1} + \frac{E_2 + E_1}{r_0} = v_2 \left\{ \frac{F+G+R}{F(G+R)} \right\} = v \left(\frac{F+G+R}{F G} \right)$$

from which we get

$$R = \frac{(V_2 - v)(F+G)}{v} = \frac{G (F_2 + F_1)(V_2 - v)}{v (V_2 - V_0)}.$$

For this test also the high resistance voltmeter will generally be found more convenient, especially if fitted with two or three shunts, so that the value of S may be varied so as to get convenient readings. As any circuit or section of a circuit can be tested by disconnecting it for a few minutes from the live mains, this test can be employed to localise a fault, the existence of which has been indicated by the test of the complete circuit. For instance, in the case of a house circuit, each circuit leaving the distribution board can be disconnected and tested in turn, and the faulty circuit so found may be further divided up by removing the branch fuses. In a similar manner sections of a network of underground mains can be tested with very little inconvenience to customers, as each section is only disconnected for long enough to take two readings of the voltmeter.

PRESENTATION TO MR. F. H. WEBB.

It is not often that one is called upon to attend so pleasant a function as that which took place at the Whitehall Rooms on Monday evening. Still rarer is it to find an electrical gathering imbued with so marked an unanimity and with so conspicuous a desire to do distinguished honour to one associated with electrical engineering. The occasion was the presentation to Mr. F. H. Webb, the retiring secretary of the Institution of Electrical Engineers.

There was a geniality suffused over the whole proceedings, which may have been partly due to the event and partly to the presence of many fair women. There were many distinguished members of the Institution present, among them Sir Henry Mance, Mr. J. W. Swan, Sir William Crookes, Prof. Hughes, Major-General Webber, Mr. H. Edmunds, and Mr. E. Manville.

The proceedings were commenced by many of the subscribers dining together, with Mr. and Mrs. Webb as guests. Subsequently a reception was held, and shortly after 10 o'clock we proceeded to the real business of the evening.

Sir Henry Mance, as chairman of the Executive Committee of the Testimonial Fund, called upon the honorary secretary of the fund, Mr. H. Edmunds, to give a short account of the initiation of the testimonial. In setting forth the details of the scheme to present a testimonial to Mr. Webb, in recognition of his long and successful service in the interests of the Institution of Electrical Engineers, Mr. Edmunds pointed out the wide interest that had been taken in the proposal, and that it had received the support of members of the Institution in all parts of the world. They had practically received £750 as subscriptions, and in accordance with the wishes of Mr. Webb, it was proposed to invest this sum in the names of two trustees, Mr. Manville and himself. An illuminated address, having the signatures of the 1,000 contributors, was then referred to by Mr. Edmunds, the text of which is as follows:—

ADDRESS TO MR. FRANCIS HUGHES WEBB,

Secretary Institution of Electrical Engineers, 1878—1898.

February, 1898.

Dear Mr. Webb,—Upon the occasion of your retirement from the secretaryship of the Institution of Electrical Engineers, we, the undersigned members, foreign members, associates, and students of the Institution, desire to give expression to the deep sense that we entertain of personal and corporate indebtedness to you.

For 20 years you have devoted the whole of your untiring energy to that office with a single mind to the interests of the Institution; and the increase in the number of members during these years, from 800 to nearly 3,000, coupled with the soundness of the financial position to which the Institution has attained in the same period, sufficiently attest the value and the success of your labours.

In conducting the work of the office, your uniform and unfailing courtesy, tact, sympathy and kindliness, have endeared you to all with whom you have been brought in contact. And now, in presenting you with this address, together with a sum of money amounting to upwards of £600, and a diamond brooch, which we beg Mrs. Webb to accept as a token of our esteem, we earnestly hope that for many years you may be spared with her to enjoy the rest that you have earned so well, and we trust that the Institution may long be permitted to have the benefit of your experience, which has proved so valuable to it in the past.

We beg also that you will regard the autograph signatures in this album as those of true and sincere friends.

We are, dear Mr. Webb,

On behalf of the subscribers,

SIGNED BY THE MEMBERS OF THE EXECUTIVE COMMITTEE.

Major-General Webber, as one of the founders of the Institution, then spoke in eulogistic terms of the long services rendered by Mr. Webb. He had joined the Institution at a time when, as the Telegraph Society of Engineers, the number of members did not exceed 200 or 300, and when the society had not been commercially successful. The speaker briefly referred to the fact that Mr. Webb, even before he joined the Institution, had been connected with several branches of engineering. He concluded by making an eloquent tribute to the manner in which Mr. Webb had conducted the affairs of the Institution.

Then Sir Henry rose to make the presentation, and in doing so, referred to the fact that Mr. Webb had served under 19 different presidents. On all occasions he had been ever ready to listen to suggestions, whether from the council, from members, associates, or students. The chairman then handed to Mr. Webb a silver box containing a cheque, and the album containing the illuminated address and the signatures of the subscribers. In doing so, he wished the recipient many years of life to enjoy the rest he had so richly deserved.

The chairman then presented a handsome diamond brooch to Mrs. Webb.

Mr. Webb, who, upon rising to respond, was received with loud applause, referred to the difficulties of his position. He had been overwhelmed with kindness, and it was impossible for him to properly express his feelings. Speaking of his long connection with the Institution, Mr. Webb said when he accepted the secretaryship he did so with the knowledge that he was really going among friends, for many of the members of the Institution were known to him previously. He thanked the members of the committee and the members of the Institution generally for what they had done. He appreciated the honour more than he could say, and his sons abroad—and he had one in India, one in America, and one in Australia—would be proud to know of the honour done to him.

The proceedings were terminated by a vote of thanks to the executive committee.

At the conclusion of the ceremony, there was a wish expressed that arrangements might be made for the collection of a second volume of autograph signatures of members, associates, and students of the Institution, as it was felt that there must be, among the 2,000 members whose autographs were not included, many who would regret that they had lost the opportunity of expressing their sympathy with the movement. We understand that Mr. Edmunds, as honorary secretary to the Testimonial Fund, will be most happy to receive any further signatures and subscriptions that may be sent hereafter to his office, 39, Victoria Street, S.W. Both autographs and subscriptions will be handed to Mr. Webb, and the total amount received will, from time to time, be announced in the Technical Press.

CORRESPONDENCE.

Shoreditch Dust Destructors.

In view of the very kind reception accorded to me on two occasions at the Shoreditch works by Mr. H. E. Kershaw, the chairman of the Electric Lighting Committee, and by Mr. C. Newton Russell, the chief electrical engineer, I greatly regret that I should have felt compelled to offer any adverse criticism to the plan of combining dust destruction with electricity works as exemplified there.

That I am impressed with the advantages arising from the conversion into electrical energy of the heat generated in dust cremation is sufficiently evidenced by the fact that I am at present designing three such schemes.

When, however, under cross-examination on the subject by the members of the Gloucester Town Council, I felt bound to place among the *contras* the inconvenience arising from the entry of dust into the electricity works.

Hot bearings and scored commutators are very unpleasant incidents, and the visits to the Shoreditch works confirmed my opinion that in order to avoid them in combined works, extra vigilance, and, possibly, extra expenditure on cleaners, would be necessary.

Your condensed report of my hour's interview with the Gloucester Town Council is, in the main, most accurate, but one or two remarks are without their context, and I venture to supply in italics below the omitted and qualifying words.

"Personally he would rather not have the dust destructor next door to his electricity works, for the one reason that the dirt and dust made it more difficult to carry the electricity works on with a dust destructor in the immediate vicinity. Besides, they could not keep the machinery and building so smart and tidy as they could if the dust destructor was half-a-mile away. . . . . At Shoreditch the dust considerably interfered with the machinery. The works there were ill-designed *for keeping out the dust*, and if he were asked to draw up a scheme of combination he should take care that the dust destructor portion was entirely closed up from the electricity works, instead of being connected by windows and doors as at Shoreditch. . . . . he would rather not run the risk of having his smart machinery interfered with, but still he believed those difficulties might be got over, and the saving undoubtedly would be what had been stated. Mr. C. G. Clark asked if there was any possibility of the dust interfering or damaging the machinery providing the works were properly constructed . . . . the nearest approach to the works not being interfered with was at Cheltenham. There the destructor was separated from the electricity works by a promenade. They had plenty of room there, more than they wanted to take in Gloucester. He knew of no place where a certain amount of dust did not come in. When he recommended the combination he had, of course, considered the pros and cons, and if they had it they must put up with the disadvantage of some amount of dust, and that would require greater care in cleaning the machinery, because there was nothing so dangerous to electric plant as dust. At Shoreditch, *on the occasion of his two visits*, some of the machinery was disabled from that cause, but as to whether he could keep it out he would be able to tell them better when he had erected the Gloucester works."

I now learn from the two gentlemen best qualified to judge that I was mistaken in supposing that the motors driving the fans to which I referred had been disabled through the dust, and I must express my regret that I made a false inference; but when I noticed that first one and then another was dismantled, I could attribute the cause to none other than "dust," of the presence of which in the electricity works there was other evidence, rather than suppose that the plant had failed from any but extraneous causes within a few months of completion.

Robert Hammond.

The Yarrow Home.

You were kind enough in your issue of May 15th, 1896, to publish a description of the Yarrow Home for Convalescent Children at Broadstairs.

I have the pleasure to report that since the opening of this institution a little over 2 years ago, no less a number than 1,299 children have been benefitted by a stay there. It will be remembered that the Home is fully endowed and no subscriptions are required, also that it is not intended for the very poor, but for children who have been well brought up and whose parents cannot afford to send them to the seaside entirely at their own expense.

During the summer months the applications for admission are far in excess of the capabilities of the Home, but in the winter it is only partly filled, and the trustees are most anxious to maintain its utility equally throughout the year. There is little doubt that the falling off in applications during the winter may arise from the fact that the Home is thought not to be a very desirable resort during the inclement part of the year, but such is not the case. The building is thoroughly warmed and ventilated, a healthy temperature being maintained throughout; and there are play corridors within and playgrounds without.

The grounds are planted and well sheltered, and there are but very few days in the year when children cannot enjoy the fresh air even when the weather debars them from going to the sea front.

T. Fredk. Myers,
Secretary of the Yarrow Home.

73A, Queen Victoria Street, E.C.

A Protest.

I notice in your issue of February 18th, an advertisement for a shift engineer, at the princely salary of £50 a year. It certainly appears to me that the unfortunate shift engineer of the future will not only be held responsible for the working of £10,000 worth of machinery for eight hours every day, but will also be expected to "tip the chief engineer" for being allowed to do it. No doubt Mr. Boot is very proud of that passage in his report which runs: "Tunbridge Wells is the only station working on the high tension system which has not made a call upon the ratepayers in the first completed year's working." It seems probable to me that the staff were called upon instead of the ratepayers. Possibly the air of Tunbridge Wells is so invigorating that shift engineers require no dinner; or, perhaps, as it is near springtime, the happy successful candidate will lightly turn his thoughts to love—and live on that. Is it not time that, in these days of successful stations, junior electrical engineers should receive a fair day's pay for a fair day's work? Mr. Boot is evidently more successful in drawing up high-sounding reports than in learning what constitutes a "living wage." My hearty sympathies are with the successful candidate.

Disgusted.

I note in your issue of the 18th that a *shift engineer* is required at Tunbridge Wells at the enormous *salary of £50 per year*, but the applicants must have had experience of high tension working.

It is, I think, an enormity that the managers of an undertaking such as Tunbridge Wells should make such an offer. The results of last year's working show a net surplus of £887, and yet this Corporation thinks that £50 a year is sufficient salary for an experienced man in such an expensive place as Tunbridge Wells. There is no excuse of poverty or a station on which losses are being made, and I think that a stand should be made against such barefaced offers. The pity of the whole business is that they will get a man (?) at the price, and I can only hope that he will give them no more than value for their money.

Some months ago I answered a private notice at the Technical College, Finsbury, for an engineer experienced in high tension work to take charge of the running, and be responsible to the chief engineer for the satisfactory working of the plant at this station. Everything went on very well until the question of salary was reached. I ventured to hint that say 35s. a week, with a good prospect of a rise would meet the case, and received in reply a *post card* from the chief engineer, if you please, stating that they could not think of paying as much as that. I afterwards heard that they had two assistants fresh from a technical college, whom they were paying *nothing*. No wonder that the station shows such good results. I believe I could make a high tension station pay if I received labour and material gratis. But, seriously, is £50 per annum sufficient for an experienced man who has to work through the night, and has such heavy responsibility on his shoulders?

I would venture to suggest that you should refuse all such advertisements in future, and by so doing you will help to break this ring of low prices, which are less than a road-scraper can obtain from the parish.

W. Fennell.

8, Ferndale Road, Leytonstone.

NOTES.

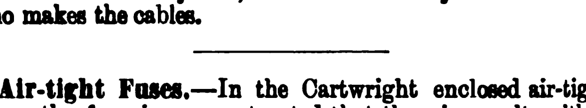
Improvements in Storage Batteries.—By means of certain improvements in battery plates, a new cell has been completed by Mr. Rankin Kennedy, which gives, we are informed, a very much greater output per pound weight than is usual. This cell has been under experiment for two years, and the object of the improvements have been to do away with the heavy grid used in battery plates, so as to render the whole of the active materials useful. Recent tests by Dr. William Peddie, D.Sc., F.R.S.E., Physical Laboratory, Edinburgh (whose figures, by the way, we should like to see for ourselves), result in the conclusion that the capacity of the new cell is 13 watt hours per pound of battery, and 32·8 watt hours per pound of positives at normal rates of discharge. The active material is not in the form of plugs, which are always liable to fall out or loosen; it is held securely in contact with conductors ramified throughout the mass. Careful tests have been made up to discharge rates equal to five amperes per pound of positives, without the least signs of buckling. The new cell will be shortly put in the market in two types, one for traction purposes, and the other for stationary wants. We hope Mr. Kennedy's battery will turn out as well commercially as it looks on paper, and if the long years of experience and knowledge of what to avoid go for anything, we anticipate that a real advance in accumulators has been made.

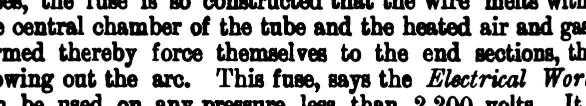
Advice to Boiler Attendants.—We are in receipt of a new issue of advice to boiler attendants, issued by the Manchester Steam Users' Association, over the signature of their new chief engineer, Mr. Chas. E. Stromeyer. In the sheets at one time issued, it was stated that the best advice the Association could give in regard to the occurrence of low water was "not to let it occur," which reminds one of *Punch's* advice to those about to marry; but there was always some, if an unconscious humour, about the Manchester Steam Users' Association, and the strain remains to-day. After a few remarks on what to do with collapsed furnaces and bare crowns, it is naively stated that, in face of these dangers, the boiler attendant may prefer to retire. Among the warnings is one to ease the safety valve before opening the manhole cover, so as to be quite sure there is no steam in the boiler. This advice is dangerous, being insufficient. Easing a safety valve is understood to imply lifting, and, perhaps, propping the lever, but the valve itself ought to be lifted; it is often heavy enough to confine steam in a hot boiler quite sufficient to lift the unbolted manhole cover and rush out in a scalding torrent. We have seen it happen.

High Speed Sentinel Steam Engines.—Messrs. Alley and Maclellan, of Glasgow, have forwarded us a copy of their new steam engine catalogue. In it are particulars of the firm's make of Westinghouse type, simple and compound engines. There are now 6,000 simple engines at work—an encouragement to the firm to build compound engines on similar lines up to 250 H.P. They have now some 12,000 H.P. of compound engines at work. The catalogue is well arranged, and the engines it describes are all shown diagrammatically, with all leading dimensions tabulated. Copies of indicator diagrams are given; these show good adjustment. All engines are made strictly to gauge and interchangeable throughout.

Dublin Cables.—In connection with the "scare" in rubber cables to which we referred in our last issue, it will be interesting to review the reported facts in connection with the underground mains in Dublin. After a number of years working without trouble, the arc light mains broke down in several places, this cable, we are informed, being small and unsuitable, apparently, for the mechanical strains it was called upon to bear from time to time. Extensions were contemplated, and the two matters were dealt with together, the Board of Trade being asked to hold an inquiry on a loan for "renewals of cable," the superintendent reporting that a complete renewal was absolutely necessary, and Prof. Kennedy, F.R.S., whose advice was sought, acting on the report of the superintendent, and, no doubt, on his appreciation of other reports on similar cables, agreeing that a complete renewal was a matter of necessity. When the Board of Trade inquiry was held it was ascertained that the money was not required for renewals of cable, but for extensions. The title of the demand was no doubt based on the theory that it would have been easier to get the loan for renewals as being pressing than for extensions, and, during the course of the inquiry, the superintendent is reported to have said that, although the cables had failed here and there, the real loss on the old cables would only be £1,300 out of the £20,000 applied for, as they wished to take out some of the old cables to enable them to change the "system." On being pressed, he admitted that an expenditure of £500 would restore the faulty cable, and they could be used again. It is difficult from the reports to reconcile these different statements, and Mr. Thompson, T.C., apparently could not, as in his examination he stated that the whole cables had been condemned by the Council, and there was never a word said about mere repair. Surely some more light should be thrown on this matter, since it would appear from the facts before us that the report of the superintendent on which Prof. Kennedy, in part, at least, would naturally rely, was not made at all in accordance with the evidence he finally gave when the question of renewals became for other reasons, no doubt, subordinated to that of extensions. The only explanation we can suggest at present is, that it was the "system," and not the type of cable, that was condemned. Still, as reported in the electrical press, the cables were stated to be in fault, possibly because the engineers who make technical reports select the system, whereas it is only the contractor who makes the cables.

Air-tight Fuses.—In the Cartwright enclosed air-tight fuses, the fuse is so constructed that the wire melts within the central chamber of the tube and the heated air and gases formed thereby force themselves to the end sections, thus blowing out the arc. This fuse, says the *Electrical World*, can be used on any pressure less than 2,200 volts. It is stated that it will not maintain an arc between its terminals when short-circuited on the mains of a 2,200-volt composite alternating dynamo. The cut-out consists of two parts, namely, the base and tube. The base is made of the best quality of Monson slate, and the tube is made of black or grey





fibre. Owing to the peculiar construction of this device, the fuse in a 3-inch tube will, it is stated, open the circuit, where other cut-outs require twice that length of fuse to operate under the same condition. This fuse has a definite length, cannot come in contact with any foreign substances, and will open the circuit in a pre-determined time on a given current. After a fuse has blown it is replaced by a new tube. Each fuse is marked with the maximum number of amperes it will carry indefinitely. These fuses are manufactured by the Shawmut Fuse Wire Company, of Boston, Mass., under license from the Goodhart Electric Company.

The Electric Migration of Colloids.—A little time ago some researches were initiated by Cöhn with a view to throwing some light upon the subject of electric migration, especially of colloids. In the first stage of the research the conclusion was arrived at that coloured ions exist, because coloured fluid follows the direction of the current during electrolysis. Nernst has also studied this subject, and our readers are familiar with most of his work. They may remember an experiment which he described in which, during the electrolysis of permanganate of potash, the MnO_4 ions moved towards the anode, and it is generally recognised now that a substance which is free to move will move in or against the direction of the current if it be electrically charged. Fine suspended solid particles, suspended in water or in turpentine, will, by reason of the static charges which they bear, move towards the oppositely charged electrode, whilst the liquid particles move towards the other electrode. More recently Cöhn, working in conjunction with Euler, found that such substances as caramel, starch and tannin, which are colloidal in character, and non-electrolytes, behave in a manner exactly similar to the behaviour of the solid particles suspended in water or turpentine; they actually move in the water towards the anode. Of course this fact has already been noticed in the case of tannin, and is the foundation of the process of electric tannin. Cöhn has also investigated the behaviour of colloids in which electrolytic dissociation might possibly take place, for example, in dialysed ferric hydroxide. The hydroxide was first purified by means of electrolysis with a silver anode, and was then submitted to a current between two layers of water. It was then observed that a dark layer moved towards the anode, whilst a lighter coloured layer moved towards the cathode. Now the layer would not pass through a parchment membrane, and hence could not contain iron ions. These observations are exceedingly interesting, inasmuch as they throw light upon a subject which is very obscure, and concerning which information is really demanded. We are glad to hear that the subject is being more fully investigated, and shall look forward to further results. The present research is described in the *Zeitschrift für Elektrochemie*, No. 4, pages 63—66.

Manufacturing Aluminium and its Sulphides.—An interesting application of electrolysis to the manufacture of aluminium, sulphide of aluminium, &c., has recently been successfully carried out by D. A. Peniakoff at Huy, in Belgium. The essential features of the process are as follows:—A single or double anhydrous aluminium salt, such as a fluoride or chloride, fused with the sulphide of an alkali or alkaline earth, together with a chloride or fluoride as a flux, yields a mixture containing aluminium sulphide, from which, in the same crucible, aluminium may be reduced, either by the action of an electric current, or by means of reducing gases (such as hyrocarbons, for example). The following formulæ present examples of the preparation of aluminium sulphide:—

(1) $Al_2 F_6 + 3 Na_2 S = Al_2 S_3 + 6 Na F.$

(2) $Al_2 F_6, 6 Na F + 3 Na_2 S = Al_2 S_3 + 12 Na F.$

(3) $Al_2 Cl_6, 6 Na Cl + 3 Na_2 S = Al_2 S_3 + 12 Na Cl.$

When the bath is constituted according to the reactions (1) or (2), if aluminium be reduced from the fused mass, the supply of aluminium sulphide is kept up by additions of aluminium sulphate and carbon; aluminium fluoride and sodium sulphate are first formed, according to the equation $Al_2 3 SO_4 + 6 Na F = Al_2 F_6 + 3 Na_2 SO_4$, and the sodium sulphate is reduced to sulphide by the carbon, with subsequent production of aluminium sulphide, according to equations (1) and (2). It is stated that even where the sulphide of aluminium produced in the bath is subjected to electrolysis, the sulphide alone may undergo the electrolytic action, and not the fluoride, as the latter requires for its electrolytic decomposition a far greater electromotive force than that which suffices to bring about the decomposition of the sulphide of aluminium. Besides, where electrolysis is resorted to, the sulphur separated from the aluminium serves, for the most part, to reduce the alkaline sulphate to the condition of alkaline sulphide, thus adding its effect to the action of the carbon.

(*Continued on page* 268.)

Bankruptcy Proceedings.—The first meeting was held last week at the London Bankruptcy Court of the creditors of John Dewhurst, electrician and sanitary engineer, 52, North End Road, S.W. The debtor, who presented his own petition, commenced business nine years ago at North Kensington, and removed about 1893 to his present premises. He attributes his insolvency to a loss of £250 sustained through the defalcations and misconduct of a former traveller. The accounts show unsecured debts £315 9s 10d, and assets £121 5s. 8d. An offer of 6s. 8d. in the £ was made to the creditors recently, but it was not unanimously accepted, and the debtor subsequently petitioned the Bankruptcy Court. No offer was now submitted, and the creditors left the estate in the hands of the official receiver to be wound up in the usual manner.

Dissolutions of Partnerships.—Messrs. F. Woolnough and H. A. Procter (Woolnough & Procter, electrical engineers, Surrey Grove, Norwich) have dissolved partnership. Mr. Procter will attend to debts.

Messrs. W. T. Burbey and H. A. Hutton (Burbey & Hutton, electrical engineers and manufacturers, 57B, Hatton Garden, E.C.) have dissolved partnership. Mr. Burbey will attend to debts.

Messrs. A. J. Fippard and C. J. Cooper (Fippard & Cooper, electrical engineers, Albert Road, Bournemouth), have dissolved partnership. Mr. Cooper will continue the business, and attend to debts.

Liquidation Notice.—A meeting of the Universal Electrical Fittings Company will be held at the office of Messrs. G. Franklin & Co., 18, Norfolk Row, Sheffield, on March 28th, at noon, to hear an account of the winding up from Mr. G. S. Greening, the liquidator.

Condensing Plants.—Messrs. Cole, Marchent & Morley, of Bradford, have issued a small pamphlet describing their standard surface condensing plants, with pumps driven by steam, electromotors, or belt. In cases where the space for the storage of water is limited the condensing plants are combined with evaporative condensers or water-cooling arrangements. There are several good illustrations of plant supplied by the firm, such as Bradford Corporation Electricity Works electrically driven centrifugal pumps, and the surface condenser and air pumps at the same station. An article by Mr. H. W. Morley on "Surface Condensers, Air and Circulating Pumps for Electricity Works," is reprinted from a contemporary. The list is a neat production.

A Directory for Exporters.—The Export Merchant Shippers' Directory for 1898, has been published by Messrs. Dean and Co., of 160A, Fleet Street, E.C. It has now reached its thirty-third year of publication, and has increased in size, until it now has nearly 1,300 pages. The contents are divided into three sections, viz., the Export Section, giving a complete list of the British exporters, with the names of their respective trading ports, and the class of goods shipped; the Trade Mark Section; and the Manufacturing Section embodying a list of traders who manufacture principally for export. There are separate sections for the various towns, Liverpool, Bradford, London, and so forth, and under these the names of exporters are given in alphabetical order. The extracts from the consular reports given under the title, "Notes on Trade," has been enlarged in the present edition by the insertion of some of the principle South American Republics, where the competition with British trade is especially keen.

Electric Drill.—On 17th inst. trials of a new electric drill were made on board the White Star steamer, *Nomadic*, at Liverpool. The Boiler Makers' Society lodged objections to its employment.

Electric Organs.—From the *Musical News* we learn that the Hope-Jones Organ Company has received an order for a large organ for St. Michael's Church, Chester Square. The instrument is the gift of a member of the congregation, and is to cost over £2,000. It will be fitted with all Mr. Hope-Jones's latest tonal and mechanical improvements. A new electric organ has also been ordered from the same firm for Ambleside Parish Church, at a cost of £1,000.

Electric Welding.—At a conversazione held at Finsbury Technical College on Friday, 18th inst., the Electric Welding Company, Limited, exhibited an automatic welding plant and a very fine collection of samples welded by their (the Thomson) process, including railway coupling links (lent by the Lancaster Railway Carriage and Waggon Company, Limited) and a complete collection of cycle parts.

Kaye v. the Croydon Tramways Company.—In the Court of Appeal on Wednesday, before the Master of the Rolls, Lord Justice Rigby and Lord Justice Vaughan Williams, the hearing was resumed of the appeal of the Croydon Tramways Company from an order of Mr. Justice Kekewich, who had granted an interim injunction restraining the carrying into effect of an agreement for the sale of the undertaking to the British Electric Traction Company. We have already referred to the case in the ELECTRICAL REVIEW. In his judgment the Master of the Rolls said that the appeal succeeded to a certain extent, and he thought the right course to adopt would be to discharge the order of Mr. Justice Kekewich, and to grant an injunction to restrain the defendant company from carrying this agreement into effect until duly sanctioned by the shareholders of the Croydon Company at a meeting duly convened for that purpose. If they chose upon proper notice, and understanding what they were about, to ratify the contract they were at liberty to do so, but it would not be right to allow this agreement to stand until that had been done. The costs of the original plaintiffs and defendants would be costs with the action, and the costs of the purchasing company would be their costs in the action. Lords Justices Rigby and Williams concurred.

Lists.—Messrs. P. C. Middleton & Co., of Aberdeen, have sent us a neat pamphlet which they are circulating, setting forth the advantages of electric over gas lighting, and giving general statements for the benefit of those contemplating the use of electric motors, electric heating and cooking apparatus, &c.

Messrs. Laing, Wharton & Down's new list of "Whardown" track tools gives illustrations and prices of track drills for drilling bolt holes, tie holes, and electric bond holes, rail saws for cutting rails quickly and accurately, and lifting jacks. These devices are being introduced for economising time and expense in track work—especially in connection with electric tramways—and at the same time considerably increasing the quality.

Messrs. Ball, Wylde & Co., of 9 and 10, Fenchurch Street, E.C., have taken up several agencies for American pumping machinery, turbines, steam and electrical machinery, &c., and have also been appointed sole agents for Great Britain by Eugen Seeligmann, of Köln a. Rh. Hansaring. We have before us a catalogue, printed in German, of the firm's manufactures in the way of electrical accessories. Prices and numerous illustrations are given of lampholders, switches, lamps, plain and fancy brackets, electroliers, insulators, casing, and a great variety of small fittings and articles.

Messrs. Handley & Shanks, electrical and general engineers, of Cork, Dublin, and Limerick, have sent us their list of electric light engines, coupled to dynamos, also gas and oil engines for electric lighting, Waverley turbines, "Taunton" dynamos, electric motors, Jandus lamp, and the improved glow lamps.

London Office.—Messrs. Henry J. Rogers & Co., of Watford, have just opened branch offices in London at 4, Bloomfield Street, London Wall, E.C. Mr. H. J. Spencer is the manager for the London district.

New Zealand Electrical Syndicate, Limited. — A petition was brought before Mr. Justice Stirling in the Lord Chancellor's Court on Wednesday for the reduction of the capital of the New Zealand Electrical Syndicate, Limited. Mr. Carson explained that the case was before his Lordship before Christmas, and was adjourned. His Lordship had expressed the wish to see some of the witnesses whom he had examined. After this he had thought proper to direct reference to an expert on certain points. It was suggested that terms might be suggested for this reference. Counsel now brought the terms before his Lordship. After counsels' speeches, his Lordship ruled that an expert electrician should be appointed as referee, and that before making his report he should hear both sides. Perhaps it would be desirable to put that direction in the order for the guidance of the referee. Counsel thanked his Lordship for his assistance in the matter, and agreed on the terms of reference of the matter to an electrical expert.

Photographic Exhibition.—The International Exhibition at the Crystal Palace, 1898, will be opened by the Prince of Wales, on Monday, April 25th—not Wednesday, April 27th.

Sell's Press Directory.—*Sell's Dictionary of the World's Press* for 1898 is before us. As usual, it is a very bulky publication, of about 1,200 pages. As the title denotes, information is given regarding the newspapers, technical journals, magazines, &c., of home and foreign countries. The newspaper man finds much of interest and utility in this directory. Not only is he informed on matters affecting national and international trade, tariffs, treaties, &c., but he has placed before him an anecdotal history of journalism, some important notes by Dr. Gordon Stables on how to keep in health, and a note of the year's events in the newspaper world. The newspaper, as an investment, and the life of the foreign correspondent, are matters which have an interest for those not connected with the journalistic profession.

Workmen's Compensation Act, 1897.—The *Western Mail*, Limited, has issued a fifth edition, revised and enlarged, of Mr. M. Roberts-Jones's handbook on the above Act. The price is 2s. 6d.

The Yorkshire College, Leeds.—The twenty-seventh annual report, 1896-7, of this college, has been issued. It gives details of the classes held and lectures given in various subjects, along with the average attendances, and notes on the financial progress.

ELECTRIC LIGHTING NOTES.

Aberdeen.—The electric lighting accounts for last year show that the income amounted to £5,707 12s. 5d., and after deducting working expenses, there was a balance of £3,111 0s. 7d. That sum had been applied—In paying interest on mortgages and loans, £1,150; in writing off as depreciation on plant, £1,024; carrying to sinking fund, £767; and leaving a surplus (carried to the reserve fund) of £169 5s. 2d.

Messrs. P. C. Middleton & Co., of Aberdeen, have been entrusted by the Town Council with the contract for the lighting of the Municipal Lodging Houses. There will be 300 lights.

Barnsley.—Mr. T. C. Miller has been instructed by the Town Council to report on electric lighting, and if such report is satisfactory, he will later design and superintend the work, subject to the approval of Mr. Bromley Holmes.

Basingstoke.—The Town Council recently referred to a special committee a suggestion to apply for electric lighting powers.

Bedford.—The electric lighting accounts just submitted show as follows:—By sale of current at 6d. per unit, less bad and doubtful debts (£12 19s. 1d.), £3,200 4s.; by sale under contracts, £13 15s. 6d.; rental of meters, £110 3s. 2d.; by public lighting to December 31st, £1,391 13s. 5d.; miscellaneous receipts, £2 8s. 11d.; total, £4,718 5s.; balance carried to net revenue account, £1,593 7s. 1d. The general balance sheet shows:—To capital receipts, £39,175 11s. 6d.; to sundry creditors, £165 2s. 8d.: to balance due to treasurer (less cash in hand, £25), £10,348 15s. 8d.; total, £49,689 9s. 10d.; by capital expenditure, £46,389 19s. 11d.; sundry debtors for current and meter rents, £1,890 19s. 11d.; net revenue account—balance at debit thereof, £1,200 4s. 6d.; stores on hand, December 31st, £208 5s. 6d. If the demand continues to increase, reductions will be made in the charges at the beginning of next year.

Brighton.—The Lighting Committee recommends that Montpelier Road and the north part of Preston Road, from Stanford Avenue to the Drive, should be lighted by arc lamps instead of incandescent, as at present, at an increased annual charge of £400.

Broughty Ferry.—The Police Commission has appointed a sub-committee to collect information *re* electric lighting.

Buxton.—Prof. Kennedy has submitted his report on electric lighting, and his estimate for the proposed municipal plant is £18,000.

Calcutta.—The Secretary of State for India recently sanctioned the appointment of an electric lighting inspector for Calcutta.

Cardiff.—The Lighting and Electrical Committee considered last week the electrical engineer's report on the condition of the cables and mains. He stated that the renewal of the cables for the arc lights, which should be carried out at once, would cost about £400. It was resolved to invite tenders for the supply of new cables.

Chester.—The minutes of the Electric Lighting Committee, which have been approved, show that a reduction to consumers of the light might be made for the current year to 5d. per unit, and for motive power to 3d. per unit.

Crieff.—The electric lighting scheme put forward by Mr. Yorke has been further remitted back to a committee of the whole Council for further consideration.

Edenbridge.—The *Kent Messenger* says that a scheme is on foot to form a company to light the district electrically. It is estimated that £2,500 is required.

Edgbaston.—St. Augustine's Church has just been fitted up for electric lighting by Messrs. Veritys, to plans and under the supervision of Messrs. Henry Lea & Son. High voltage lamps are used, and they are arranged around the capitals of the pillars.

Edinburgh.—The Electric Lighting Committee has recommended the supply of watertight chambers for the underground switching apparatus. The Committee also recommends the laying down of a new "feeder" from Dewar Place along Grove Street, and on to Merchiston (cost, £1,400).

The Embankment Lighting.—The London County Council last week adopted a supplemental estimate of £3,300 for the electric lighting of the Embankment. An estimate of £22,000 was previously adopted.

Faversham.—The Town Council will not sanction Mr. McCreel's proposal to apply for a provisional order for electric lighting, and they state that when the time comes they will do the work themselves.

Glasgow.—The Electricity Committee submitted to the Corporation last week reports from the tramways engineer, the assistant electrical engineer, and the lighting inspector on the subject of lighting the Springburn tramway route. The assistant electrical engineer recommended that the mains should be immediately laid down for supplying current for private purposes to consumers along the line of Parliamentary Road to Springburn, and in the same trench a cast-iron pipe to carry arc lighting cables. He reported that the cost of supplying and laying down the feeders and network necessary for private lighting would be about £12,566, and the arc lighting mains £1,446, making a total of £14,012. That is if both were laid at the same time; but if street lighting alone were arranged for, the cost would be £7,022, and the cost of re-opening the trench and laying mains, &c., later on for private lighting would be £9,525; total, £16,547. The first course would, therefore, show a saving of £2,535, and the corporation approved of this scheme, and the work will go forward. The arc lamps will, with a few exceptions, be suspended from the poles on both sides of the route. There will be in all 104 lamps required. Certain designs and estimates submitted by Messrs. W. McFarlane & Co. have been accepted for bases, brackets, &c. The cost for current is estimated at £18 per lamp per annum.

Grimsby.—The Council has confirmed the Lighting Committee's recommendations to ask Prof. Kennedy to report on electric lighting.

Hackney.—The Vestry, after playing with the electric lighting question for the past few years, has just considered a number of proposals submitted by parties willing to take over the provisional order. Among those who made offers were Messrs. C. & A. Sax, Imperial Electric Lighting Company, Siemens Bros. & Co., Laing, Wharton & Down, Electric Extension Syndicate, County of London and Brush Provincial Company. The Electric Light Committee, after considering the various proposals, reported that the scheme submitted by the Electric Extension Company, Limited, covered all the points which the Committee desired to see included. "They offer to collect, destroy, and dispose of the dust at 4s. per ton, to supply public and private lighting at 3½d. and 5d. per unit respectively, and for power purposes only at 2½d. per unit. They satisfied us," say the Committee, "on searching and careful questioning, that they were able to undertake the work and carry it out promptly. They are practically manufacturing firms of the highest standing (the British Insulated Wire Company and Ferranti, Limited); and they were able to show us, from contracts actually carried out by them for more than 100 public bodies and lighting companies, that their experience in dealing with such matters is of a very wide and satisfactory character. No other company tendering impressed us with anything like the same confidence as the representatives of this company did. They undertake to deposit £5,000 with the Vestry—a guarantee for the carrying out of the work at 2½ per cent. per annum. They further undertake to pay the Vestry £500 towards their expenses in obtaining and transferring the order." It is estimated that this will mean a saving of £5,047 per annum to the parish in the collection and disposal of dust. The Vestry has rescinded its previous resolutions, and the Electric Extension Company's scheme will come before it again in a few days.

Hammersmith.—The Vestry has decided to construct two new sub-stations, one in Lime Grove, Uxbridge Road, and the other in St. Stephen's Avenue, Goldhawk Road; £150 is to be expended upon finishing and furnishing the electricity works' offices.

Hampstead.—The Finance Committee has recommended the Vestry to apply to the London County Council for permission to borrow £50,000 to meet the expenditure on the electric lighting capital account.

Harbour Lights.—The Clyde Trust and the Corporation Electricity Department have been conferring as to the lighting of the harbour by electricity. The question was remitted to the officials of both bodies, with special reference to the illumination of the Prince's Dock.

Kensal Town.—The Chelsea Vestry will oppose the Metropolitan Electric Supply Company's scheme to lay mains in Harrow Road unless the company undertakes to supply electricity for Kensal Town at 4d. per unit.

Kingswinford.—The District Council has resolved to make application for a provisional order.

Leamington.—Mr. Hammond has reported to the Electric Light Committee *re* electric lighting, and he advises that it would be to the interests of the Corporation to arrange that the works of the Midland Electric Lighting Company should continue their operations until the whole of the present consumers are transferred to the new mains. Mr. Hammond reports that with an installation of 15,000 lights at 6d. per unit, there would be a profit of £3,000, sufficient for interest and sinking fund, on £50,000 capital.

Lewisham.—The Great Western Electric Light and Power Company has followed up its previous letters to the Board of Works, by saying that it is prepared to undertake the destruction of dust at cost price, guaranteed not to exceed 1s. 6d. per ton; and, in connection therewith, to take over the dust destructor recently erected, at the price paid by the board to the makers for it, and work it at once, pending the erection of electric supply works, when the combined operations would be carried on. The company also propose to introduce the Brighton system. The public streets would be supplied with 16 C.P. lamps at a cost of about 33s. 4d. per annum.

Liverpool.—The electrical engineer (Mr. Holmes) has reported that during the month of January 62,681 electric lamps, equivalent to 16 C.P., had been supplied from the Corporation mains for private lighting, and 7,924 for Corporation lighting. This showed an increase of 2,944 for the month.

Luton.—The Electric Light Committee has discussed the report by Mr. Snell on electric lighting at great length, but considers that further information should be obtained from other towns before the matter is decided. A deputation is to visit several places. Application is to be made for an extension of the provisional order from June 27th, 1898, for 12 months.

Manchester.—A Local Government Board inquiry was held on 15th inst. regarding applications by the Corporation for loans for various purposes, including £16,000 for electric lighting. Alderman Higginbottom gave some details of the undertaking.

Mexico.—The Dresdner Bank communicates that, according to telegraphic advices received from Mexico, the central station of the Mexican Electric Works, Limited, has been so far advanced that the lighting of the City of Mexico was commenced on the 14th inst., and proved a complete success. The installations for the private lighting and the supply of electrical power are making rapid progress, and it is anticipated that these parts of the works will be opened in course of the summer.

Morecambe.—At the last Council meeting there was a long and somewhat heated discussion with regard to a site for fixing a refuse destructor in connection with the electric light generating station.

Morley.—The Corporation are wanting an electrician-in-charge and a junior. See our "Official Notices."

Motherwell.—A deputation has inspected the Whitehaven electric lighting plant, &c.

Newington.—The Vestry decided last week to proceed with the electric lighting scheme, of which plans and specifications had been submitted by Messrs. Kincaid, Waller & Manville. Application is to be made to the London County Council for a £40,000 loan.

Poplar.—The Board of Trade has been asking the Poplar Board what it proposes to do with its electric lighting order. The County of London and Brush Company had been corresponding with the Board of Trade on the matter. The Poplar Board has now decided to put its order into force at once over the compulsory area.

Rhyl.—Mr. Dale recently appeared before a committee to ascertain their views as to proceeding with the electric lighting of the lake, &c. The question was deferred for the present.

Shoreditch.—At the Vestry meeting held on 15th inst., Mr. Kershaw, chairman of the Electric Lighting Committee, informed the Vestry that an accident occurred at the electric lighting station on the previous Saturday, which resulted in the district being plunged into darkness for a while. Fortunately it was not attended by any loss of life or injury to limb, although the explosion was of a serious nature. By some unexplained reason a small quantity of water—probably condensed steam—found its way into the cylinder of one of the engines, which burst, doing about £300 worth of damage. The whole cost of the damage, Mr. Kershaw explained, would be borne by the contractors, and a further report would be presented.

South Shields.—The Board of Guardians have appointed a Committee to consider the question of electric lighting for the whole of the workhouse.

Swansea.—The disposal of the tramways and the introduction of an electrical company into the town have, according to a local paper, caused a stir in corporation circles in Swansea. A sub-committee recommends that action be taken at once to carry out the provisions of the electric lighting provisional order.

It is understood that the Council has decided to proceed with the provisional order, and is consulting Mr. Manville on the subject.

Winchester.—The City Council, after receiving Mr. Ruthven Murray's report on the Electric Lighting Company's scheme, has informed the Board that it has no objection to the proposal.

Yarmouth.—The income in January from the electric light was £531 5s., of which private consumers furnished £426. After meeting the costs of production, there is a surplus of £316 12s., out of which £190 has to be deducted for capital repayments and interest charges, making the monthly net profit £126 12s. There are now 258 customers, using 11,993 lamps.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Bournemouth.—By 13 votes to 8 the Bournemouth Town Council has again resolved to oppose the two electric tramway schemes which have been on foot for some time.

Bristol.—The Sanitary Committee have held several special meetings to consider the Parliamentary Bills of the Bristol Tramway Company with regard to the extension of their system and the use of electric power, have submitted to the company a statement of the conditions on which they will advise the Council to allow the extensions and the use of electricity. The committee abandon their former demand that the electricity shall be taken from the Corporation supply, but raise several other points which may prove subjects for debate. The company are required to agree that no employé shall be employed for more than 60 hours a week. Lines on which electric traction is to be used are to be specified and the system stated. The Corporation are to have the right to, but not to be compellable to purchase the proposed power station; if the power station be purchased, the company are not to have the right of jointly using it for working tramways not purchased by the Corporation, nor are they to have the right to use posts, rails, &c., of tramways purchased for conveying energy to lines not purchased. The Corporation are to retain powers with regard to the position of posts and overhead wires and other matters as in the 1894 Act. The company are not to supply electric current to other companies or persons within the city. The Corporation may use the company's posts for electric light purposes. The company are not to be entitled to require the Corporation to supply them with electricity. No alteration is to be made in the dates at which the Corporation's power of purchasing existing tramways will arise, and the date at which the Corporation may purchase the power station and proposed extensions are to be the same as for the present horse tramways. Additional capital is to be put up to auction instead of at present being issued to existing shareholders at a price determined by the company. Safe arrangement is to be made for payment to the Corporation of an annual sum and for reduction of fares. As to this last condition, no suggestion is made as to the sum or what reductions are desired.

Mr. Faraday Proctor, the Corporation electrical engineer, is to visit Liverpool, Manchester, Leeds, Bradford, and Sheffield, in search of information to lay before the Bristol Sanitary Committee to enable them to make up their minds on the proposals of the Bristol Tramways C. mpany.

Central London Railway.—At the Sheriff's Court, Red Lion Square, Holborn, last week, Mr. Burchell and a special jury had before them a claim by the trustees of the late Frederick J. Blake, against the Central London Railway Company for £539 for the purpose of repairing the residence, No. 2, Marlborough Gate, Hyde Park, which is alleged to have suffered damage by subsidence due to the works of the railway company. It was alleged that the house in question had been structurally injured by the works of the company either primarily or by reason of the bursting of a water main, owing to the tunnelling operations. On behalf of the railway company Sir Douglas Fox and others gave evidence. It was contended that the system of tunnelling with the Greathead shield prevented any possibility of injury to adjacent buildings, and that the subsidence must have been caused by the bursting of the water main owing to internal pressure. The jury returned a verdict for the railway company on the ground that the damage was done by the bursting of the water main, for which the railway company had not been shown to be in any way responsible.

Dublin.—A question having arisen between the Council and the three United Tramways Companies as to a power station at Ringsend, it is now stated by the *Irish Times* that an agreement has been arrived at by which "In consideration of permission being granted by the Corporation to the companies, or any of them, to electrically connect their system of tramways with the company's proposed generating station at Ringsend Road for the working of their system of tramways, or any portion thereof, in connection with their lines within the City of Dublin, the said three companies shall undertake not to employ the electrical current for any purpose other than the haulage of their cars and the lighting of them, and of the standards or posts wherever it may be found necessary to do so, within the City of Dublin, without first receiving the sanction of the Corporation in writing."

Dublin and Lucan.—At a meeting of the Dublin and Lucan Steam Tramway Company it was resolved to issue debenture stock and preference shares for the purpose of providing the electrical equipment for the lines.

Dudley.—It is stated that the Electric Traction Company has accepted a tender for converting the steam tram line from Dudley to Stourbridge into an electric line, and the work is to be executed within six months from the date of its commencement.

Edinburgh.—A proposal was before the Lord Provost's Committee last week for the construction of an electric tramway from Preston Street *viâ* Dalkeith Road and Niddim, to Portobello, returning by Meadowbank and Waterloo Place. The matter was deferred.

Kirkcaldy.—The British Electric Traction Company recently wrote stating that it would be willing to take up the question of electric tramways for Kirkcaldy. The Town Clerk reported that a representative of the company had visited the town.

Leeds and Bradford Light Electric Railway.—We have on several occasions given brief notes on the progress of this scheme which, it will be remembered, is being promoted by Power and Traction, Limited, who propose connecting the two towns by means of an electric tramway on the overhead trolley system—an inter-urban line over the main highway. The population of the districts affected is over 700,000, and five district councils are interested in the scheme. The proposals came before the Light Railways Commissioners (Mr. G. J. R. FitzGerald and Col. Boughey, R.E.) at the Leeds Town Hall on 17th inst., and there were present to oppose representatives on behalf of the Leeds Corporation, Bradford Corporation, the Midland Railway Company, and the Great Northern Railway Company. With such extensive opposition it might reasonably have been expected that it would go hard with the scheme. Mr. Arthur Graham Hopkins, electrical engineer, of Westminster, produced the plans of the proposed line, which had been prepared under his direction. He stated that for 15 years he had had considerable experience in the construction of light railways. The gradients involved in the present scheme were generally easy, with one exception at Stanningley, but this was trifling to what could be done by electric traction. The object of the project was to afford more convenient and cheaper facilities for intercommunication. Mr. W. N. Stewart, of Westminster, one of the founders of the American Association of Electrical Engineers, whose experience comprised 13 years with Mr. Edison, of New York, also gave evidence in support of the scheme, which he said would have an important effect in increasing the prosperity of the districts passed through. His experience had proved to him that a multiplicity of administration operated against the success of a scheme of this description. At the close of the inquiry the chairman said: "We consider the utility and convenience to the public of this proposed light railway to be established. But the objections of the two corporations to a private company undertaking the work and management within their respective areas most certainly require very serious consideration. In the absence of Lord Jersey, we shall not make any further statement or express any further opinion to-day, but we trust that the result will be a resumption of negotiations. If it is desired, we shall be very happy to do anything in our power to facilitate a settlement." It is believed that an electric tram service at short intervals and low fares is a very important improvement on the present railway service. The decision of the Commissioners in this case is of considerable importance. It shows that they are not disposed to let schemes fall through unless there is good reason, and their offering to aid the parties in arriving at a settlement is very satisfactory.

Light Railways.—In the House of Commons on Monday, in reply to Mr. Bainbridge, Mr. Ritchie said that up to the present time 16 orders had been made by the Light Railways Commissioners, and submitted to the Board of Trade for confirmation. Of these, four had been confirmed by the Board of Trade after modification, and five others would shortly be ready for confirmation. One order had been remitted to the Light Railways Commissioners for further consideration, and in the case of the remaining six orders the time for lodging objections had not yet expired. None of the undertakings authorised made any claims for financial assistance from the Treasury or local authorities. Grants, however, had been provisionally sanctioned by the Treasury in cases which were still under the consideration of the Light Railways Commissioners.

Liverpool.—The Tramways Committee has appointed a deputation to visit Hamburg for the purpose of inspecting the tramways, and the methods of working the service and the management of the workshops.

Middlesboro'.—The British Thomson-Houston Company, Limited, is pushing forward the construction of the electric tramways. The poles are being rapidly erected. The trucks for the car bodies are expected to arrive in this country by the end of the month from America. The car bodies (being constructed at Birkenhead) are also expected to be finished shortly. The three multitubular boilers for the depôt in Bridge Road, Stockton, are being rapidly fitted up in position in the power house. The overhead wire has already arrived, and is on the ground ready to be put up, but in the meantime the company are waiting for brackets.

Nottingham.—A deputation has visited Bristol to inspect the electric tramways and the power station. It is understood that as a result of this visit the deputation will recommend the adoption of overhead electric traction throughout Nottingham.

Paisley.—An extraordinary meeting of the shareholders of the Paisley Tramways Company was held in private last week, when a resolution was adopted ratifying an agreement between the company, Messrs. A. and J. Faill, Robertson Street, Glasgow, and the British Electric Traction Company, Limited, the effect of which will be to empower the last-mentioned body to work the present tramway system by electric traction, and to carry out alterations and extensions.

Peterborough.—A local paper refers to a proposed electric tramway scheme which is being promoted for the district by a syndicate.

Salford.—The report of the sub-committee on electric traction recommends that the Council should undertake the future working of the Salford tramways on the electric overhead wire system, and that the current for working the cars should be provided by the Electric Lighting Committee. By 33 votes to 1 the Council has instructed the committee to prepare estimates of the cost of carrying out a scheme put forward for Salford. The committee's report contained the following:—"In reference to the tramlines to

Eccles, Patricroft, Swinton, and other places reached through Salford, there would be no difficulty in providing electric power to work these lines from the power station required for the Salford lines; or electric power might be supplied from any electric power station within those districts. The reconstruction of the lines to adapt them to this system could either be undertaken by their respective owners or by the Salford Corporation under special agreements. All these points presented no mechanical or electrical difficulties, and no doubt could be arranged between the several authorities on terms mutually advantageous. In order to give an approximate idea of the structural work required for this proposed working of the Salford tramways, it must be remembered that most of the existing tramlines in the borough had been in use for many years; the rails were not of the strength found most suitable for either horse-car or electric-car work, and therefore it would be requisite to provide new rails throughout, except as to some lines very recently relaid. In re-organising the tramway system it would be well to change all the existing single track routes to double tracks, laying parallel lines in adjacent streets wherever the streets were too narrow for a double track, with side spaces for cart traffic. Some additional lines of tramway, in extension or in deviation of existing lines, were also advisable. The total result, according to a plan provisionally prepared, would be that in place of their present 8½ miles of double lines and 3¾ miles of single line and crossing loops, a total of 20¾ miles of single track, they would have 12·8 miles of double track, 4·3 miles of single track used like double track in parallel streets, and 2·5 miles of single track with crossing loops—a total of 32·4 miles of single track."

Stoke-on-Trent.—The Parliamentary Committee has recommended that the Town Clerk write to the British Electric Traction Company, and to the North Staffordshire Tramways Company urging them to carry out the arrangements which were come to at the time when the Tramways Extension Order (1896) was passed, and inform them that unless they carried out their several obligations the Corporation would take such steps as they might be advised to enforce the same.

Swansea.—Shareholders in the Swansea Tramways and Improvements Company have been notified that a meeting to confirm the sale of the tramways will be held to-day, and adds that the directors have entered into a provisional agreement for the purchase by the British Electric Traction Company, Limited, of the whole of the undertaking, property, and assets of the company, on terms which they believe will be acceptable to the shareholders. The purchase price will, if this agreement be carried into effect, provide for the payment of £5 per share to the holders of ordinary shares of tramway capital, and of £10 for each preference share.

The Power Distributing Schemes.—In the opposition to the Bill of the General Power Distributing Company for electric lighting powers, Bakewell will join with Belper, Matlock Bath, Mexboro', North Darley, and Swinton.

Yarmouth.—The Yarmouth and Gorleston Tramway Company are negotiating for the purchase of the Yarmouth 'Bus Company's undertaking, including horses, vehicles and premises, their intention being to make the Yare side stables, which are situated between Yarmouth and Gorleston, a station for the generation of electricity, in order that they may be able to run electric trams between Yarmouth and Gorleston.

York.—The chairman of the York Tramways Company told the shareholders last week that they looked forward to being able to give a better service to the public by the application of electricity, without materially increasing their expenses, and they hoped that the Corporation, with whom they were in negotiation, would meet them fairly. No progress had been made in the matter, because the Corporation had such difficulty in making up their minds with regard to the electric light.

TELEGRAPH AND TELEPHONE NOTES.

Australian Cable Delays.—A joint deputation from the Melbourne Chamber of Commerce and the Melbourne Chamber of Mines has waited upon the Hon. J. G. Duffy, the Postmaster-General, and strongly protested against the delays to which cable messages were liable. The deputation furnished evidence that these delays were almost entirely traceable to the South Australian lines. Mr. Duffy, in the course of his reply, announced that the Eastern Telegraph Extension Company had offered to extend the proposed new Cape cable from the Cape to Mauritius, and thence to Albany and Adelaide, provided the Australian Governments would agree to renew their present subsidy of £32,400 per annum for 20 years.

Replying to Mr. Hogan, in the Commons last week, Mr. Chamberlain said there had been no interruption in our cable service with Australia during the last two months, but the land service had been several times interrupted. He had nothing to report as to any alternative service, which was not being pressed at the present time by any colony.

Hawaiian Cable.—Mr. James A. Scrymser, president of the Pacific Cable Company, appeared at Washington, on January 18th, before the House Committee on Interstate and Foreign Commerce to advocate a contract with the United States, whereby the company would transmit all official messages for $175,000 a year, for 20 years, from San Francisco to Hawaii, China, and Japan, with a proposition to extend it to Australia for $75,000 additional per year. He said that during the Venezuela trouble it had cost the Government $5,000 for one diplomatic message, and no one knew what the Government's aggregate expense was in this connection. According to a New York exchange he said that it would take 8,000 miles of cable from San Francisco to Honolulu.

L.C.C. and Telephone Matters.—A statement by the Highways Committee on the telephone service of the National Company was before the Council on Tuesday. The matter will come up again before the first meeting of the new Council.

The Telegraph Service.—The Council of the Associated Chambers of Commerce recently requested the Postmaster-General to receive a deputation on the subject of telegraphic communication. The Duke of Norfolk, in reply, says that the Lords of the Treasury have been consulted, and they do not consider it advisable to propose the abolition of the separate account for telegraphs. With regard to the extension of telegraphic facilities in rural districts, his Grace has given the matter special consideration, and the concessions given on the occasion of the Diamond Jubilee were evidence of the desire of the Government for the increase of such facilities. In the course of the year many new telegraph offices have been opened and costly extensions are in hand. The total number of telegraph offices of all kinds now open to the public is 10,432.

Telegraphic Communication between Calais and Dover.—In the House of Commons last week, Mr. Hanbury, in answer to Mr. Cohen and Mr. Stuart-Wortley, with regard to the mail packet from Dover to Calais having left Dover in a storm on November 29th and having had to put back, when a telegram sent from Calais to prevent her from starting had been delayed by having to reach Dover through London, said the delay did not take place on that account. It arose from an interruption caused by the storm with the line between Calais and the French landing station, about six miles off, necessitating the transmission of the telegram by a circuitous route. There was not sufficient traffic to justify the allocation of direct wires between France and Dover or Folkestone. The transmission of the telegram through London did not involve any appreciable delay. The Postmaster-General was considering whether any arrangements could be made whereby the consequences of an interruption to the normal communications would be rendered less serious than on that occasion.

Trunk Telephone Lines.—In reply to a memorial of the Associated Chambers of Commerce regarding the irregularities and delays in the trunk telephone service, the Postmaster-General has replied that the department is continuing its efforts to provide a widespread and efficient system; during the period from April 1st to December 31st, 1897, the construction of additional trunk wires, amounting to upwards of 3,000 miles, was undertaken. Some of these have been completed, and others are being rapidly constructed.

CONTRACTS OPEN AND CLOSED.

OPEN.

Belfast.—March 8th. The Corporation wants tenders for the wiring of the new police cells, Chichester Street. Electrical engineer, Mr. V. A. H. McCowan. See our "Official Notices" February 18th.

Belgium.—April 1st. The Municipal Authorities of Seraing are inviting tenders for the concession for the supply of electrical energy in the town for public and private lighting purposes during a period of 30 years. Particulars may be had from, and tenders to be sent to, the College des Bourgmestre et Echevins, Seraing, Belgium.

Berlin.—March 15th. The Municipal Traffic Deputation of the Town Council has opened a competition for the construction of several new electric tramways in that city. Exhaustive details concerning this project are contained in the *Elektrotechnische Zeitschrift* of the 13th inst., which mentions that proposals will be received by the Stadtische Verkehrsdeputation Rathhaus III, Berlin, by March 15th.

Blackpool.—March 22nd. The Corporation wants tenders for a tubular boiler, superheaters, condensers, rectifiers, boosters, transformers, lead-covered cables, arc lamps and pillars. Borough electrical engineer, Mr. R. C. Quin. See our "Official Notices."

Carlisle.—February 25th. Tenders are being invited for the erection of the central station buildings in James Street. City engineer and surveyor, Mr. H. C. Marks, 36, Fisher Street.

Coventry.—March 8th. The Electric Light Committee wants tenders for the supply and erection of engine house, separate exciting and surface condensing plant, also pipework, switchboards and instruments for extensions of the municipal electricity works. Consulting engineer, Mr. Robert Hammond. See our "Official Notices" February 18th.

Denmark.—March 12th. Tenders are being invited for the supply of the engines, dynamos, accumulators, &c., required in connection with the new central station at Frederiksberg, near Copenhagen. Tenders to be sent to the Frederiksberg Sporveis-og Electricitets Aktieselskab, Gammel Kongerie, 140, Copenhagen V., from whom particulars may be obtained.

France.—March 31st. Tenders are being invited by the Municipal Authorities of Saint Chamond (Loire) for the concession for the lighting of the public streets of the town, either by gas or electricity. Particulars from, and tenders to be sent to, La Mairie de Saint Chamond (Loire).

Glasgow.—February 28th. The Corporation wants tenders for the hire or purchase of dynamos and engines, direct coupled or belt driven, capable of providing 1,100 B.H.P. and spare power equal to 25 per cent. additional, also two rope driven dynamos to run at a speed not exceeding 500 revolutions per minute, and capable of providing 200 H.P. each at a potential of 230 H.P. The plant must be delivered by August 1st. Engineer, Mr. W. A. Chamen. See our "Official Notices" February 18th.

Glasgow.—February 28th. The Corporation wants tenders for the supply of lead covered cables and accessories for twelve months, accumulators, motor transformers, motor driven boosters and switching apparatus. Mr. W. A. Chamen, engineer. See our "Official Notices" February 18th.

Italy.—March 1st. Tenders are being invited by the Municipal Authorities of Cassino (Caserta) for the concession for the electric lighting of the public streets of the town during a period of 30 years. Tenders to be addressed to El Municipio de Cassino (Caserta), Italy. Particulars from ditto.

Italy.—March 2nd. Tenders are being invited by the Municipal Authorities of Piacenza for the establishment of a central electricity generating station in the town for lighting and power purposes. Particulars may be had from, and tenders to be sent to, El Municipio di Piacenza, Italy.

Liverpool.—March 8th. The West Derby Board of Guardians wants tenders for supply and erection of boilers, engines, dynamos, batteries, wiring, &c., for the lighting of the Mill Road Infirmary. Consulting engineer, Mr. T. L. Miller. See our "Official Notices" for particulars.

Northwich.—March 5th. The Weaver Navigation Trustees are inviting tenders for the construction and erection of the necessary electric power plant for lighting and working the new swing bridges at Northwich. Current will be supplied by the Northwich Electric Supply Company. Engineer, Mr. J. A. Saner, M.I.E.E. See our "Official Notices" February 11th.

Pembroke (Ireland).—March 5th. The Lighting Committee wants tenders for the supply and erection of various plant, machinery, &c., for electric lighting. See our "Official Notices" February 18th for full particulars. Consulting engineer, Mr. Robert Hammond.

Roumania.—March 15th. Tenders are being invited by the General Direction of the Roumanian Post and Telegraphs in Bucharest for the supply of 56,000 metres of galvanised iron and steel wire.

Shoreditch.—March 8th. The Vestry wants tenders for the supply of electric cables and sundries, also engineers' tools, ironmongery, &c. See our "Official Notices" February 18th.

Sunderland.—February 25th. Tenders are invited by the Corporation for the supply of various cables, pipes, service boxes and stoneware casings for the year. Borough electrical engineer, Mr. J. F. C. Snell. See our "Official Notices" February 18th.

The War Office.—April 27th. The Secretary of State for War is prepared to receive offers, competitive designs and specifications for the supply of portable electric search light apparatus. Particulars from the Director of Army Contracts, War Office, Pall Mall, S.W. See our "Official Notices" February 4th.

Victoria.—March 21st. The Telegraph Department of the Victorian Government Railways is inviting tenders for the supply of alternating current transformers and one main switchboard. Tenders to the Telegraph Superintendent's Office, Spencer Street, Melbourne.

Wallasey.—March 17th. The District Council wants tenders for the supply of engine, alternator, exciter, two Lancashire and one water-tube boilers, and condensing apparatus. Engineer, Mr. J. H. Crowther. See "Official Notices" February 11th.

Warsaw.—The Warsaw Municipality is inviting applications re supplying the town with electrical power for purposes of lighting, tramways, &c. Further particulars, says *Daily Tenders*, may be obtained from, and applications to, the President of the town of Warsaw.

Watford.—March 16th. The District Council wants tenders for the supply and erection of various plant for the electric lighting of the district. For details of the seven sections see our "Official Notices" February 11th. Mr. W. C. C. Hawtayne, consulting engineer.

West Ham.—March 8th. The Council invites tenders for wiring and fitting up various buildings, including the Town Hall, police court, Corporation stables, fire stables, &c. Mr. J. Steinitz borough electrical engineer. See our "Official Notices" February 18th.

CLOSED.

Belfast.—The Electric Committee has accepted the tender of Messrs. T. Parker, Limited, to supply and erect a 200-kw. steam dynamo for lighting and traction. A sub-committee is preparing a summary of all that has been done by the Council in the way of investigating the electric traction question.

Bradford.—The Gas and Electricity Committee has accepted the tender of Messrs. Cole, Marchent & Morley, of Bradford, to supply additional condensing apparatus at the new electricity works for £1,600. In view of the complaints regarding meters at present in use, a new style at £2 per meter less is to be adopted.

Leith.—The contract for boilers and accessories for the electric lighting installation has been given to Mr. Geo. Sinclair, of Albion Boiler Works, for £3,313. Messrs. Carrick & Ritchie will supply an 8-ton travelling crane for £240. We have already mentioned that the contract for the engines, dynamos, &c., is in the hands of the India-Rubber Company at £8,844. Mr. W. A. Bryson is the Corporation electrical engineer. The cost of cables and laying same is estimated at about £8,000.

Walsall.—The number of consumers has increased to 102. The following tenders for extension of the plant have been accepted, viz.:—Messrs. Bumstead & Chandler, engine, £910; Thomas Parker, Limited, for supplying a continuous dynamo and a spare armature, £1,160; and Callender's Cable and Construction Company, Limited, supplying and laying on the solid system in a cast-iron trough, three new concentric cables at the price of 19s. 6d. per yard (exclusive of the cost of excavating).

Wimbledon.—The following is a full list of the tenders sent in for the municipal electric lighting scheme:—

		£	s.	d.
Buildings.				
Messrs. Manter		2,990	0	0
" Thomas & Edge		3,261	0	0
" Lorden & Sons		3,333	0	0
" Burgess	(accepted)	3,338	0	0
" Wall & Co.		3,578	0	0
" Buller & Co.		3,720	0	0
" Jerbury & Co.		3,984	0	0
Machinery.—*Section A, Boilers.*				
Messrs. Babcock & Wilcox	(accepted)	2,482	0	0
The Southern Cross Engineering Company		2,795	0	0
The Haythorn Tubular Boiler Company		3,397	0	0
Messrs. Hornsby		3,505	10	0
Section B.—Condenser and Pipes.				
Messrs. Babcock & Wilcox	(postponed)	2,681	0	0
Section C.—Crane.				
Messrs. Carrick & Ritchie		130	0	0
" Higginbotham		132	0	0
The Bedford Engineering Company		149	0	0
Messrs. Spencer		152	0	0
" Babcock & Wilcox		155	0	0
" Taylor & Hubbard		155	0	0
Section D.—Steam Engine and Dynamo.				
The Southern Cross Engineering Company		3,980	0	0
Messrs. Parsons		4,124	0	0
" Crompton	(accepted)	4,181	0	0
The Electric Construction Company		4,368	0	0
Messrs. Easton, Anderson & Goolden		4,575	0	0
" Mather & Platt		4,629	0	0
" Siemens		4,690	0	0
The Brush Company		5,170	0	0
The General Electric Company		5,615	0	0
Messrs. Fowler		5,981	0	0
Section E.—Switchboards.				
Messrs. Edison & Swan		454	18	0
" James White		568	10	0
The Electric Construction Company		570	0	0
Messrs. Crompton		621	0	0
" Siemens	(postponed)	692	0	0
" Sharp & Piper		721	10	0
The General Electric Company		750	0	0
Messrs. Fowler		755	0	0
" Ferranti		833	0	0
Mains.				
Messrs. Henley & Co.	(accepted)	15,793	12	9
" Glover & Co.		16,127	17	4
" Callender		16,537	8	4
" Siemens		17,417	11	3
The British Insulated Wire Company		20,833	19	2
The Western Electric Company		20,950	19	10

FORTHCOMING EVENTS.

1898.

Friday, February 25th, at 6.30 p.m.—The Institution of Electrical Engineers. Students' visit to the Shoreditch electricity supply station. Applications at once to the Students' Hon. Sec. (Mr. S. Grant, 28, St. Mary Abbot's Terrace, W.) as the number will be limited to 20.

At 8 p.m.—The Institution of Civil Engineers.—Students meeting. "The Problem of Train Resistance," by C. E. Wolff, B.Sc., Stud.Inst.C.E.

Sunderland Corporation tenders due to-day.

Saturday, February 26th, at 4 p.m.—Physical Society in the Chemistry Lecture Room, Keate's Lane, Eton College. The Rev. T. C. Porter will describe:—1. A new theory of geysers. 2. A new method of viewing Newton's Rings. 3. Experiments bearing on the sensation of light. 4. A method of viewing lantern projections in stereoscopic relief. 5. Winter observations on the shadow of El Teide, with a new method for measuring approximately the diameter of the earth. 6. Temperature of the water of Niagara.

Monday, February 28th, at 3 p.m.—The Institution of Junior Engineers. Visit to the Westinghouse Brake Company's Works, York Road, King's Cross.

Last day for Glasgow Corporation tenders.

Tuesday, March 1st.—Röntgen Society. General meeting at the rooms of the Medical Society, 11, Chandos Street, Cavendish Square, W., Prof. S. P. Thompson presiding. Paper on "The Photographic Activity and Penetration of Röntgen Rays at Different Vacua," by Mr. J. H. Gardner; other papers by Mr. Wilson Noble and Mr. Hall Edwards. Mr. Isenthal will show some new apparatus.

Wednesday, March 2nd, at 8 p.m.—Society of Arts. "Kites: Their Theory and Practice," by Captain B. F. S. Baden-Powell. Prof. W. Grylls Adams, F.R.S., will preside.

Thursday, March 3rd, at 8 p.m.—Chemical Society, Burlington House. Papers to be read:—"Note on the Preparation of Dry Hydrogen Cyanide and Carbon Monoxide." John Wade, B.Sc. and Laurence C. Panting, M.B. "Production of Some Nitro- and Amido-Oxylutidines." J. N. Collie, Ph.D., F.R.S. and T. Tickle. "Production of Some Nitro- and Amido-Oxylutidines, Part II." J. N. Collie, Ph.D. F.R.S. and Miss L. Hall. "The Interaction of Magnesium and Solution of Copper Sulphate." E. Divers, M.D., F.R.S.

Royal Institution. First of a series of five lectures on "Recent Researches in Magnetism and Dia-Magnetism," by Prof. Fleming.

Friday, March 4th, 8 p.m.—At the Westminster Palace Hotel. The Institution of Junior Engineers. Paper on "An Outline of Patent Law and Practice," by Mr. Arthur H. Stanley, Fel.C.I.P.A., Member.

NOTES.

(*Continued from page* 257.)

American Dynamos.—Our friends on the other side have been most active in developing the applications of the dynamo-electric machine. But few improvements have originated in America. The modern dynamo, with all its perfections, is the product of European, and mostly British, science, yet it finds a far greater field of application in the States; and some things, although well known here and not much used, are sometimes promoted in America as novelties, and meet with considerable acceptance. A case in point at present is the introduction of what is called the multi-voltage dynamo, a form of dynamo long ago patented in this country by Kennedy, brought out subsequently by Herr Rothert in Germany, and by Mr. Sayers and Mr. Kingdon in Britain. No doubt our friends will work this style of machine "for all it is worth," but at the same time it is only fair to point out that the construction of machines to give several voltages from one armature and one commutator is well known, its principles and methods of operation are well understood, and in this country, at any rate, any manufacturer is quite free to construct, and use, and sell such machines when they are wanted. In back numbers of the ELECTRICAL REVIEW several references will be found to these multi-voltage or multi-circuit dynamos.

Rail Bonds.—Not long ago we remember coming across a reference by some would-be learned authority in electric traction to the idea that heavy rails are necessary for the new method of traction because large currents are conveyed along them! It is, of course, quite true that 80, 90, and 100-lb. rails are now used where formerly a weight of 45 or 50-lb. was considered enough; but the notion that such an increase is required for improvement of the return circuit is strangely belied by the fact that engineers responsible for electric tramways are satisfied with bonding a 90-lb. rail with two No. 0 copper bonds! Assuming that the capacity of the bonds at any joint does not exceed 25 per cent. of the maximum capacity of rail, a 90-lb. rail would require no less than three No. 000 bonds at each joint. It is evident, then, that rail and bond capacities do not correspond at all, nor is it necessary that they should. The usual rail area is enormous for the current it has to carry, and the trouble as to resistance and waste is not here but at the joints, where insufficient and irregular contacts are, we fear, frequent. A single track of 90-lb. rail has a capacity in area of steel equal to at least 2½ square inches of copper. In the *Street Railway Journal* Mr. E. T. Birdsall touches upon this point, mainly for the purpose of drawing attention to a new type of heavy copper rail bond which he has devised, suitable for soldering to the under side of the rail base. It consists essentially of a number of copper wire horseshoes, placed one above the other to the number of, say, five, with a long flat-footed sort of elliptical base cast on to each vertical series of ends. The whole thing is claimed to be cheap—costing about 6s. put into position—and possessing great flexibility. With 60-foot rails, Mr. Birdsall gives the cost of bonding as £45 per mile, single track.

Different Men, Different Minds.—Some of our contemporaries do not think very highly of the promoting and financing interests engaged just now in the development of electric tramways at various places in this country, and profess to believe that these interests are very largely bent upon making great profits for themselves out of what are to be regarded as speculations instead of investments. We are glad, however, to note that the *Railway World* has a different view of the matter, and in its last issue comments upon this subject much more favourably. Our contemporary considers that so far, with scarcely an exception, every electric traction enterprise has been initiated by genuine investors who have desired to secure an enduring success for a useful industrial undertaking. As a special instance of this praiseworthy type of promotion there is brought forward the Oldham, Ashton and Hyde Electric Tramway, the share capital for which was lately offered to the public and subscribed several times over, and we think from such well based information as has been at our command, that the statements of our contemporary are justified. It is much to be hoped that this happy condition of affairs will long continue, and that we shall not in regard to electric traction see any of the disastrous methods only too common in the early days of horse tramways, when financiers bought or obtained concessions cheaply, sold them at high figures to subsidiary companies, and then left the latter to struggle on as best they could with enormously inflated capital accounts.

Electricity on Warships.—The following letter from "Velox" appeared in Wednesday's *Times*:—

The explosion on board the cruiser *Maine* has startled the world. No doubt it will lead to very full inquiry, but at this inquiry other considerations and tests beyond those which are commonly accepted should be brought into notice. Our modern war vessels are fast becoming threaded by wires, hidden away in every direction. Very large currents of electricity circulate through these wires and also in the dynamos. The common care is to see that all the electrical communications are well insulated, and with good insulation the matter and consideration ends. But ought it to do so? It is well known that insulation has no retarding effect upon induction, and that when large currents are in circulation, or meeting arrest, the induced electricity extends for many feet beyond the insulation. Hence we have only to supply some other material—such, for instance, as a length of wire rope, a length of chain, or even a collection of shell or other metal cases—suitably placed, and a spark may be obtained at many parts of the ship. The thought certainly rises whether these powerful currents ought to be employed on board vessels which carry gunpowder and dynamite. The latter is an unstable compound and may, beside, be affected by these induced charges. It certainly seems to me that our modern warships have as much to fear from these electrical actions as they have to fear from the enemies' shot.

Lectures.—On behalf of the Literary Society in connection with Marylebone Presbyterian Church, a lecture was delivered on Wednesday evening, last week, by Mr. F. Tandy, A.I.E.E., upon the subject of "Electric Waves," with special reference to signalling through space. Numerous experiments, and illustrations by limelight, demonstrating the possibilities of telegraphic signalling between two points without connecting wires, were shown by Mr. Tandy, assisted by Messrs. G. E. and R. J. Taylor. Interest was added to the lecture, by some actual recorded signals being on view, that had been transmitted recently between Alum Bay (Isle of Wight) and Madeira House, Bournemouth, an approximate distance of 14 miles, which had been kindly supplied for the lecture by Signor Marconi. Mr. Tandy had the loan of apparatus from W. H. Preece, Esq., C.B., engineer-in-chief at the Post Office.

Before the Shipley Textile Society on 14th inst., a paper was read by Mr. A. R. Foster, of Bradford, on "Will Electricity Advance the Loom?"

Before the Glasgow Technical College Scientific Society on 12th inst., Mr. E. H. Judd read a paper on "High Speed Engines for Electric Lighting." He gave interesting figures regarding the engines employed in London and the provinces. Taking London with 19 electricity stations, of 16 of which the lecturer had information, containing 176 engines, there were 116 Willans, 10 Belliss and 18 other types, giving a total of 32,182 H.P., or 70 per cent. of the total horse-power in these stations, supplied by high speed engines. In the provinces, of 604 engines in electric light stations, 357 were high speed.

Prof. S. P. Thompson lectured on "Electric Motive Power" at Carpenters' Hall, E.C., on Monday last week.

Under the auspices of the Dundee Institute of Engineers, Mr. A. G. Seaman lectured at Dundee, on 18th inst., on "Underground Systems of Electric Traction."

Electricity in Municipal Engineering. — Mr. R. Bowens, writing to the *Electrical World*, finds fault with the power department of municipalities. He finds, especially in western towns, that water supply is often obtained from distributed wells each provided with its own steam plant of the direct acting and therefore wasteful description. In place of so many separate plants and attendants he would collect all power at one central station with a minimum of attendance, and distribute therefrom electrical power to the outlying stations to drive the pumps. In many towns, especially where there is some water storage, the pumping can be chiefly done by day so as to provide load for the lighting plant of a municipal light station and a regular economical rate of work can be maintained. Electricity is also recommended for sewage sterilisation on the Hermite or Woolf systems. In one case, for a population of 30,000, the power required was only 15 H.P., and the cost per annum barely 13d. per head, and this would be halved if the electricity came from one central station. The necessity of regularity in burning refuse makes very convenient the use of power in pumping, so as to maintain a constant demand for steam the whole 24 hours through. For small towns, in which many things are municipalised, there is much to be said for the author's suggestions. Indeed, in London, there might be much done to economise fuel and expense all round, could men only agree to mutual economies. Could one only see all the power generation of London in the sweep of one's eye, there would be visible many men banking up boiler fires and doing their best to check steam raising. Others would be equally busy trying to keep steam against a heavy draught, there would be seen electrical station boilers lighting up at night and pumping stations shutting down, and generally about twice the fuel burned that need be, and quadruple the labour expended. There would be seen clouds of steam blowing to waste in the air, and thousands of houses half warmed by extravagant laborious fires that might be nicely warmed from waste heat. In fact, no one realises the economy that would be possible were municipal authorities half alive to their duties and responsibilities. Merely for pumping, sewage treatment and street lighting, our author considers that a refuse burner, perhaps assisted with good fuel, would find a fairly steady load for every hour of the twenty-four.

Institution of Mechanical Engineers.—On the second evening of the recent meeting of this Institution held in London, Mr. Johnson occupied the chair, and the proceedings were opened by Sir Douglas Galton moving a vote of thanks to Mr. Bache on his retirement after many years' service to the Institution. The speaker referred, says *Engineering*, in feeling terms to the devotion to his duties which, for so long a period, the late secretary had displayed, and he felt sure that the good wishes of all members of the Institution would follow Mr. Bache in his retirement and well-earned rest. For many years to come he hoped that Mr. Worthington, who, he was sure, would prove so able a successor, would be able to consult his predecessor in times of difficulty such as were sure to arise in the conduct of every institution. The motion was seconded by Mr. Jeremiah Head, who said that it had been his lot to become President at a crisis in the history of the Institution, the tiding over of which was one great turning point in its career. He was the first president who served after the appointment of Mr. Bache as secretary. There was, unfortunately, a great deal of friction at the time, and if there had been a secretary of less good feeling and of less common sense the results might have been disastrous. The position was so strained at one time that Mr. Head had almost despaired of grappling with it, and had thought of resigning his post. It was then that the loyal support accorded to him by the secretary was most felt, and, happily, by the good offices of their friends and by the exercise of self-restrain and sound common sense, they had passed through the crisis successfully. He had much pleasure in seconding the resolution. The President next invited any member from the body of the hall to speak on the motion. In reply, Mr. Bernard Dawson, Mr. Hawksley, and Mr. Oughterson added their recognitions to the valuable services rendered by Mr. Bache during his long career of 43 years as a servant of the Institution. The motion was then carried with acclamation. Mr. Bache thanked the members for the kind way in which they had passed this vote. The incident was one of a series of kindnesses such as he had constantly received from the members of the Institution. The work of his lifetime had been a great pleasure to him, and he would say now, that if he had to start in life again and could select his career, he would choose no other position than the one he had filled. He could not answer all the kind things that had been said of him by Sir Douglas Galton and Mr. Head in proposing and seconding the motion, nor to the no less gratifying remarks of Mr. Dawson, Mr. Hawksley, and Mr. Oughterson. He would, however, make one reference to what Mr. Head had said about the trying time they had passed through when that gentleman was president of the Institute. Mr. Head had attributed too much to him; and, indeed, it was the sterling character of the president that had carried the Institution through that difficult and trying period. He cordially thanked the meeting for the way in which the vote had been carried, and would be pleased to assist the Institution to the fullest extent of his ability, should his advice or assistance be required by Mr. Worthington, who, he felt sure, would so ably fill the position to which he had been appointed.

Old News.—Our French contemporary, *L'Electricien*, informs its readers that a Russian engineer, whose name is not very formidable—no worse, at least, than Romanow—has invented a new form of electric suspension railway. Moreover, he has devised three types of it—one for mails and parcels, a second for goods traffic of medium weight, and a third for heavier goods or for passengers. Figures as to cost of construction, working expenses, &c., are also given, but in a form which cannot be understood. However, they do not affect this remarkable discovery (!) of a "telpher" system; which is, apparently, exactly what could be seen at work in this country 10 or 15 years ago.

X Rays in Medical Work.—The statement that at a Liverpool hospital X rays were utilised in no less than 57 cases during the year 1897, is followed up by the treasurer of the St. Thomas's Hospital, Albert Embankment, who says, in a letter to the *Times*, that at St. Thomas's as many as 416 patients passed through the X rays department during the year. So great is the pressure of work, that an assistant to the officer in charge is about to be appointed.

To Battery Makers and Users.—An interesting offer now being made by an American house for the purpose of popularising the Willard storage battery is worthy of attention from battery makers in this country. The firm requests anyone interested in storage batteries for whatever purpose, and especially for large power or lighting plants, to investigate the mechanical and electrical construction of the Willard cell. Inquiry is invited and scientific tests courted, and the company undertakes to supply anyone with the means by which he may investigate for himself the merits of the battery, and for the purpose of such test and comparision a single cell of any size is offered at half the net price. An investigation of cells which have been in use from two to five years is invited. There is no better recommendation for apparatus than to place it before the public for free and full investigation, and our American friends appear to appreciate the truth of this in the present instance.

W. T. Glover & Co., Limited.—Under our "New Companies" this week will be found a notice of the registration of this company, with a capital of £200,000, to take over the business of the well-known cable and wire manufacturers, Messrs. W. T. Glover & Co.

Electricity Meters.—A course of five lectures on "Electricity Meters" is to be given at the Finsbury Technical College, by Mr. Louis J. Steel, A.I.E.E., commencing March 3rd. See our "Official Notices."

Personal.—We notice in the *Bulletin Hebdomadaire of Posts, Telegraphs, and Telephones*, that it is probable that M. Raymond, the actual administrator of telegraphs in France, will retire shortly from the public service, and will be succeeded by M. Wünschendorff, who is well known to the English telegraph world. M. Wünschendorff at present is one of the inspectors general of French telegraphs. M. Raymond will be a difficult man to follow on account of his knowledge, industry, and urbanity.

NEW COMPANIES REGISTERED.

International Engine Patents Development Company, Limited (56,144).—Registered February 17th with capital £3,750 in 1s. shares, to acquire the assets and liabilities of New and Mayne, Limited, to adopt an agreement with New and Mayne, Limited, and D. F. Basden, its liquidator, and to carry on the business of mechanical, electrical, and general engineers, engine builders, and manufacturers of oil, steam, or electrical motors. The subscribers (with one share each) are:—O. Lloyd, 38, Montpelier Road, Brecknock Road, N.W., gentleman; J. W. Baldwin, 39, Northway Road, Loughboro' Junction, S.W., clerk; J. P. Bennett, 274, Ivydale Road, Nunhead, S.E., clerk; A. M. Mallett, 47, Bawdale Road, East Dulwich, S.E., clerk; S. F. Patmore, 8, Alvington Crescent, Dalston, clerk; A. Robinson, 8, Stone Buildings, Lincoln's Inn, solicitor; J. Shinkey, 13, Model Buildings, Gray's Inn Road, W.C., clerk. The number of directors is not to be less than three nor more than five. The first are R. Hunt, W. Shrimpton, and A. G. New; qualification, 500 shares; remuneration, £300 per annum divisible. Registered office, 33, St. Swithin's Lane, E.C.

Gas and Electric Light Consumers' Protection Association, Limited (56,088).—Registered February 14th with capital £1,000 in £1 shares, to establish and carry on a system of periodically inspecting the registering indexes of gas and electric light meters. The subscribers (with one share each) are:—W. H. Robbins, 8, Linacre Road, Willesden Green, journalist; J. Cristol, 7, Richmond Road, Bayswater, financier; F. Thomas, Roeborough Park, Harrow, journalist; W. C. Daniels, 39, Chardmore Road, Stoke Newington, merchant; D. Davies, 50, Brondesbury Road, Kilburn, accountant; J. Cottrell, 83, Balmoral Road, Willesden Green, editor; F. C. Evans, 52, Queen Victoria Street, E.C., solicitor. Registered without articles of association by F. E. Evans, 52, Queen Victoria Street, E.C.

W. T. Glover & Co., Limited (56,124).—Registered February 16th with capital of £200,000 in £1 shares (100,000 £5 per cent. cumulative preference), to acquire the business carried on by H. Edmunds and G. B. Samuelson, at Springfield Works, Salford, Lancashire, as W. T. Glover & Co., to adopt a certain agreement, and to carry on the business of manufacturers of cables and lines for electrical purposes, electrical engineers, and contractors, manufacturers of electrical apparatus, and suppliers of electricity. The subscribers (with one share each) are:—H. Edmunds, 71, Upper Tulse Hill, S.W., electrical engineer; G. B. Samuelson, 7, Cadogan Gardens, S.W., electrical engineer; W. P. J. Fawcus, Derwent Bank, Keswick, engineer; J. Morton, 132, Waterloo Road, Manchester, manager; J. W. Moore, 28, Devonshire Street, Higher Broughton, Manchester, accountant; R. Taylor, 1, Weaste Road, Weaste, Manchester, cable maker; S. Hartford, 17, Woodland Avenue, Higher Broughton, traveller. The number of directors is not to be less than three nor more than five; the first are:—H. Edmunds, G. B. Samuelson, W. P. J. Fawcus, and H. P. Holt. Qualification, £2,000; remuneration as fixed by the company. Registered by Rowcliffes, Rawle and Co., 1, Bedford Row, W.C.

OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

Salisbury Electric Light and Supply Company, Limited (41,414).—This company's annual return was filed on January 8th, when 1,307 shares were taken up out of a capital of £20,000, in £1 shares. £1,013 15s. has been paid, and £293 5s. is in arrears.

Railways' Electric Supply Syndicate, Limited (52,812).—This company's statutory return was filed on November 13th, when 7,000 shares were taken up, and issued as paid, out of a capital of £10,000 in £1 shares.

Silicon Electric Lamp Syndicate, Limited (47,238).—This company will not be proceeded with, as the patent for the acquisition of which the undertaking was formed have been otherwise disposed of, and the name of the company will be struck off the register.

Rand Central Electric Works, Limited (48,712).—This company's annual return was filed on January 7th, when the capital of £300,000 in £1 shares was taken up in full; 25,000 shares are considered as paid, and £275,000 has been received.

Single Wire Multiple Telephone Signal Company, Limited (16,857).—This company's annual return was filed on December 24th, when 374 shares were taken up and paid for in full out of a capital of £5,000 in £10 shares.

Smithfield Markets Electric Supply Company, Limited (53,354).—This company's statutory return, made up to November 29th, was filed on December 11th, 1897, when 73 shares were taken up out of a capital of £100,000 in £5 shares. £1 per share has been called, and £7 paid.

Taylor & Tucker Art Metal Company, Limited (28,892).—This company's annual return was filed on January 17th, when 4,400 shares were taken up out of a capital of £5,000, in £1 shares, and paid for in full.

Telescriptor Syndicate, Limited (47,685).—This company's annual return was filed on January 14th, when 39,507 shares were taken up out of a capital of £40,000, in £1 shares; 35,000 are considered as paid, and £4,507 has been received.

Sussmann Electric Miners' Lamp Company, Limited. (47,821).—This company's annual return was filed on November 30th, 1897. The capital is £80,000 in £1 shares (1,500 deferred, 39,250 preference, and 39,250 ordinary). 1,500 deferred, 27,073 preference, and 28,488 ordinary shares have been taken up. 1,500 deferred, 17,950 preference, and 17,943 ordinary shares are considered as paid. £1 per share has been called on the others, and £19,247 has been paid, leaving £421 in arrears. £191 has been paid on 376 forfeited shares.

Thompson, Ritchie & Co., Limited (35,835).—This company's annual return was filed on January 14th. The capital is £5,000 in £10 shares (200 preference). All the preference and 140 ordinary have been taken up, and 100 preference and 70 ordinary shares are considered as paid; £10 per share has been called on the rest, and £1,700 has been received.

Townsend, Tamplin & Makovski, Limited (53,914).—This company's statutory return was filed on January 6th. The capital is £20,000 in £10 shares (1,000 "A" and 1,000 "B"). 350 "A" and 401 "B" shares have been taken up, and 401 of the latter are considered as paid. £10 per share has been called on the rest, and £3,650 has been received.

Automatic Electric Railway Signal Company, Limited (37,636)—This company's annual return was filed on December 23rd, when 5,940 shares were taken up out of a capital of £10,000 in £1 shares; 4,300 shares are considered as paid, and £1 per share has been called on the others. £1,647 10s. has been received, including £7 10s. paid on 15 forfeited shares.

African Trans-Continental Telegraph Company, Limited (37,855).—This company's annual return was filed on January 4th, when the capital of £140,000 in £1 shares was fully subscribed. £116,450 has been paid, and £23,550 is in arrears.

Amazon Telegraph Company, Limited (44,532).—This company's annual return was filed on January 20th, when the capital of £250,000 in £10 shares was taken up, and paid for in full.

Electrical Copper Company, Limited (48,068).—This company's return was filed on January 18th, when the whole capital of £500,000 in £1 shares (150,000 preference) was taken up. The ordinary shares are considered as paid, and £1 per share has been called on the others. £148,266 10s. has been paid, and £1,733 10s. is in arrears.

CITY NOTES.

National Telephone Company.

The twenty-first ordinary general meeting of the National Telephone Company, Limited, was held on Thursday, last week, at Cannon Street Hotel, Mr. James Staats Forbes presiding.

In moving the adoption of the report, the Chairman said that knowing as they did the very great difficulties by which they were surrounded in carrying out the telephone business, they felt that the figures were exceedingly satisfactory, and they trusted that those present and those absent who had studied them as either affecting the past half-year or the past year, and who carried their knowledge back to former years, would be as satisfied as the board were with the progress the concern was making. They would observe that the growth of the business in the half-year had exceeded by £67,600 the receipts of the corresponding half of 1896. The working expenses had increased reasonably in relation to the large increase of the receipts themselves, and the accounts showed that the net result for the half-year, after deducting the Post Office royalties amounting to £46,000, was an increase of £23,474. In respect of subscriptions already received for services to be rendered in the coming year—that was to say, the year they were now in—they had the large sum of £473,586 in hand, an increase of £58,872. The available balance, £156,435, would enable them to do certain things, namely, to pay a dividend at the rate of 6 per cent. per annum, less income-tax, on the first and second preference shares, 5 per cent. per annum, less income-tax, on the third preference shares, and 6 per cent. per annum, free of income-tax, on the ordinary shares. That was really the long and short of the whole business; that was the outcrop of the working for the half-year. They would see by paragraph No. 6 that they proposed to transfer £40,0^0 to the reserve fund, and to carry the balance of £10,034 forward. That £40,000 that they carried to the reserve was £5,000 more than half-year than they had been in the habit of carrying to that fund for some time past. They next came to the capital expenditure—a very serious matter, but not unduly serious, seeing the progress of the business. They had expended the sum of £267,375 on capital accounts, which was a pretty good lump for one half-year; but it was only, after all, the embodiment of a growing business. In the half-year they had erected 5,633 additional exchange and private lines, and besides that there had been considerable expenditure in what really came to a transformation of the system from overhead to underground wires. The overhead system was attended with enormous difficulties, which rather increased. They imposed upon the company certain risks from time to time which not only caused a great deal of liability, but a great deal that was harassing in working the undertaking. The underground system was free from those contingencies. It was costly, of course, at the beginning; but as it secured greater efficiency in the conduct of the service, and at the same time safeguarded the company against serious risks, such as damage to the property from snowstorms, and dislocation of the service, they had come to the conclusion that the sooner they could substitute the one system for the other, the better it would be for the public and for the company. They had no powers over the streets, and had been confronted with great difficulties in making the change; but, happily, the difficulties experienced in that direction originally, had to a great extent been overcome, owing to patience, great diligence, and a great deal of interest, which the directors in various places individually exercised, together with the energy of the general manager, engineers and officials, and some of the more important centres had been enlightened enough to listen to arguments, and to enable them, upon something like reasonable terms, to carry out those transformations in those great centres. The result was that the moment these works were finished, there was a very perceptible improvement in the service, and an immediate decrease of the actual ground for complaint. They had to pay the great Corporation at Manchester the compliment of admitting that they were the first to realise that their duty was not to the company, but to the public, and several other places had followed suit. There were now many places where they were suffering greatly from the want of those facilities. London was one of them, but they were not without hope that London would follow the lead of Manchester, and also other great towns, in view of the great and growing importance of this service, and that they would grant reasonable facilities, without which it could never be made perfect. Between December 31st, 1896, and December 31st, 1897, there had been an increase of £113,800. They had paid the Post Office in royalties £89,238, being an increase of about £10,000 over the corresponding year, the net income had increased by £103,800, and the working expenses had increased by £74,900, which was rather a larger proportion of the gross income than was quite agreeable, although if challenged they should be able to defend it. The net result for the year showed an increase of £28,929. One was constantly being told how bad the service was, how costly it was, how extravagant the whole foundation was, and how much better it could be done by other people, and they justified the statement by certain figures. Either they must be living in perfect illusions, and must be absolutely densely ignorant of what they had to do, or else the other gentlemen outside must be somewhat ill-informed. He was afraid they were ill-informed. The popular theory was, that in London they could get a magnificent telephone service for about £20, and in the country for £5 or £6. That was not their experience, and they had had now a good deal of experience in the working of the business. In the year they had increased their subscribers' wires in London by 2,671, and, after all, wire was a factor. In all other centres of the United Kingdom the increase had been 9,110. That made the total increase in the year of 11,781 exchange wires, and brought the total, on December 31st last, up to the respectable number of 17,371 wires in London, and of 88,817 in all the other places, or a total of 106,188. That seemed a satisfactory progress. It was 18 per cent. in London and 11·43 per cent. in other places, or 12·48 upon the mean. The 1,219 wires in London cost, in actual cash, £53 12s. 8d. apiece to erect them, and the 4,414 in the country £45 16s. each, and that money had all to be found and buried in the earth, or put into the air, before they got a sixpence of return upon it. Now what became of those fallacies they had had drummed into them by a great many people—adventurous persons—and, what was more singular, by reputable organs which directed the public intelligence? Those figures could not be controverted, but they were inconvenient for certain people. Now, as to the awful rapacity of the company in regard to its charges: the average subscription in London for the whole year was £14 10s. 6d., and in the country £8 10s. 10d. That did not seem to be such a very extravagant charge, in any case, nor was the disproportion in London so great as they made it out to be, when they considered that London cost £53 12s. 8d. each wire, and more, to work, as against the cost in the country of £45 15s. The fact was, they wanted four or five years' subscriptions in hand to pay the first actual cost before a single telephonic message could be sent. The Post Office royalties came to no less than £89,000 of hard-earned sovereigns. What would be the effect if the Chancellor of the Exchequer could be persuaded to forego the royalties? Well, it would have the effect of taking £1 12s. 10d. off the London subscription, and thereby reduce it to a shade over £12, and it would take 18s. 2d. off the subscriptions in all other places. All that was conveniently ignored, and they were told that they should go to Stockholm or Norway, or some remote parts of the world for parallels. Circumstances had arisen which had seriously affected the comparison for the whole year, because in the year ended December, 1896, they had some portion of the trunk revenue, whereas that trunk revenue had entirely disappeared in the year ended December 31st last. They had, however, made up the loss sustained, which was a considerable figure. He did not know whether the substitution of the dual trunk system for their old one had improved the general convenience. In some places it had, but in other places they heard complaints that it was not quite so good as it used to be when the company was the sole worker of it. Of course, there was now a multiplication of delicate operations, anyone of which might fail and cause inconvenience or delay.

Lord Harris seconded the motion, which, after some remarks by Mr. Hastie, was agreed to.

The Kensington and Knightsbridge Electric Lighting Company, Limited.

The directors' report states that during the year the number of houses and shops connected with the system has increased from 1,325 on December 31st, 1896, to 1,620 on December 31st, 1897; while the number of lamps calculated on the usual basis of 8 candle-power has increased from 119,955 to 137,953. Additional capital required by the company during the year has been raised by the issue of £1,160 4 per cent. debenture stock, producing £1,240 and 2,000 second preference shares, offered to the shareholders at a minimum price of £6 per £5 share, were subscribed for, producing £12,219 12s. 6d. The directors have strengthened the renewal account by transferring to it £8,061 7s. 1d., making the total amount placed to that account £20,497 13s. 10d. After providing for the above amount, and paying the dividends on the 6 per cent. first preference shares to June 30th, 1897, on the 5 per cent. second preference shares to September 30th, 1897, and an interim dividend at the rate of 8 per cent. per annum on the ordinary shares for the first half of the year, the balance standing to the credit of the net revenue account for the year 1897 is £7,263 11s. Of the above sum, £1,450 has been appropriated to the payment of the first preference dividend to the end of the year, and £300 has to be set aside to meet the portion of the dividend on the second preference shares accrued to the same date, leaving £5,513 11s., out of which it is proposed to pay a further dividend on the ordinary shares, at the rate of 12 per cent. per annum for the past half-year, making, with the interim dividend paid to June 30th, 10 per cent. for the year. This will leave a balance of £1,163 11s.

Bristol Tramways Company.

The half-yearly meeting of this company was held last week, the chairman (Mr. W. Butler) presiding.

The Chairman, in moving the adoption of the report and the declaration of a dividend at the rate of 6 per cent., said: Our receipts from the tramways' department show an increase of £9,494; this is, of course, largely made up of receipts from additional lines opened during the half-year, though by no means an inconsiderable portion of it is contributed from the horse lines, on which in consequence of better weather and increased service we have received more money. On the expenses side we can hardly give any minute comparison, as the amount of work done during the half-year so far exceeded that of the corresponding period. Under the heading of "horseing and traffic expenses" you will observe that the one item showing a large increase of nearly £3,000 is "wages of staff," which now amounts for the half-year to over £20,000. With regard to the items under the heading of "general expenses," these too have increased somewhat, consequent upon the additional business: the same remark applies to "renewals and repairs." We shall find that the repairs and maintenance of our tramway permanent way and rolling stock will cost very much more now that we have a large proportion of our system worked by mechanical power. The balance of net revenue is £16,859, against £12,378 in the corresponding half, being an increase roundly of £4,500, but this is as it should be, seeing that our total capital expenditure is £100,000 more than it was at this time last year. We have now had between two and three years' experience in the working of electric lines, and to-day, out of a total route length of 20 miles, no less than 8½ miles are worked by us as electric lines, leaving 11½ miles of horse lines, so that we have got practical acquaintance in not only the receipts, but the expenditure side of the account. It will be seen from our balance-sheet that, notwithstanding this large proportion of electric lines, we are no more than holding our own in the way of dividend-earning capacity. Many who have been shareholders for years past know that the normal working expenses were about 80 per cent. Since the advent of electric traction on nearly half our system we have managed to reduce the average to 75 per cent. We are generally credited throughout the country—at least in tramway circles—with being able to work a tramway as economically as most people, but I may tell you that our experience of electric traction, after 2½ years, goes to show that our working expenses in that department cannot be reduced below 60 per cent.

The chairman then proceeded to criticise the attitude taken up by the Electricity Committee of the Corporation, and eventually the report was adopted.

G. R. Blot & Co., Limited.

A statutory meeting of this company was held at Cannon Street Hotel last week, Mr. Thomas Parker in the chair.

The Chairman said the future of the company was well secured owing to the fact that they had orders in hand and in view, and a very effective staff to carry out the requirements of the company. The capital of the company had been largely subscribed by English and French shareholders, and there were amongst both some very influential people. The French company, La Compagnie des Accumulateurs Electriques Blot, had been very successful, and has just received an order from the "Secteur" of the Champs Elysées, for a battery of 10,000 ampere-hours, discharging at the rate of 2,000 amperes per hour, one of the largest batteries in the world (if not the largest). Those who knew something of accumulators will understand the magnitude of this one, and he questioned if there was so large a one at present built. The company had 15 tons of plates to handle per week, so that we had every reason to hope that they will do quite as much at their factory at Wednesfield. The directors were proceeding as quickly as possible with the erection and fitting out of our new works near Wolverhampton, and in a few weeks would be able to commence delivery of accumulators on a large scale. The new company had everything in its favour: works admirably situated, with every facility for cheap transport by canal, railway, and the like. The freights being so reduced and rent so cheap, it was more than probable that handsome dividends would soon be paid. Situated as their works were right in the very heart of the electrical world, there was every reason to hope for a favourable result.

Elmore's French Patent Copper Depositing Company.

Mr. J. H. Duncan presided, on Wednesday, at Winchester House over a meeting of the first mortgage debenture holders of the above company to consider a proposal for the purchase of the founders' shares of the Société Française d'Electro Metallurgie, which constitute, practically, the main asset of the company. The sale of the shares would enable the sum of 6s. in the £ to be paid to the first mortgage debenture holders in discharge of their debt.

The Chairman said that for many months he had been trying to get an offer for the founders' shares of the French company which would be acceptable from their point of view. It had taken him many months to work from one figure to another until he got in the neighbourhood of £10,000, and then he thought it worth speaking to them about. They would remember that the company was taken out of liquidation at the time they sold to the French company under a scheme provided by the Court, which gave to them, as creditors, a first charge, represented by debentures for £35,000. Practically the one asset they then had in their hands was the bulk of 5,000 founders' shares, and certain rights upon the French company, viz., that after 10 per cent. had been distributed to the French shareholders, there should be a certain surplus coming over to them—he thought it was about 35 per cent. of the surplus profits to come to them. He did not know whether any of them was sanguine enough to think there would be any surplus coming. They took it simply as it was offered; they had had £60,000 from the company in other ways, and they had to take it. As a matter of fact, the Frenchmen had had to raise an immense amount of capital; they had had two increases of the capital, and were talking about a third, and had found that to work up a copper business, they had to pour a good deal of solid gold into it. A French company paying 10 per cent. was a *rara avis*, and it would be well to build a museum to put it in. He did not think that 10 per cent. would ever be put, and seeing a chance of getting something solid for the debenture holders, he thought it his duty to do so. They had a small amount of £600 in hand, and a few bonds, worth £1,000, and they had also £800 of shares in the company. Altogether, after paying certain liabilities and expenses, they would have left about £12,900. In the circular they suggested that 6s. should be paid to the debenture holders, but that would only take £10,300, and the sum they had would really pay 7s. 4½d. He would move that the 6s. be paid, but it was open for them to propose more.

Mr. Shummer seconded the motion.

Mr. Holmes moved that 7s. 4d. be paid.

Mr. Saunders said he would like to move that an honorarium be given to the chairman, who had worked so hard for the debenture holders.

After discussion, it was agreed that 7s. 4d. in the £ be paid, but that 5 per cent. should be divided for the amount to be paid to the debenture holders *pro rata*, and presented to the chairman for his valuable services.

The India-Rubber and Gutta-Percha Company, Limited.

An ordinary general meeting of this company was held at Cannon Street Hotel on Wednesday, the Hon. Henry Marsham presiding.

The Chairman said that, in accordance with the wish expressed by shareholders, the debtor and credit side of the balance-sheet had been expanded; the contingent liabilities were also set forth. The turnover in the general business had been greater than that of any previous year, and the first six weeks of the present year showed a still further increase. On the other hand, very keen competition was met, and the desire to keep up the quality of goods made their task an arduous one. The rise in the price of rubber had had the effect of compelling the principal manufacturers to notify increase of prices in rubber goods. Their steamers had been employed during the year, and the works at Silvertown and Persan were being kept in a state of efficiency. After referring to the strike, which closed one department of their works, the chairman said that the normal condition of things had been restored. The great fire at Melbourne had destroyed their agency there, but the agent had informed them he had secured fresh offices, and their claims would be shortly made on the fire offices.

He concluded by moving the adoption of the report, Mr. Silver seconded.

General Trevor objected to the form of the auditor's certificate, and asked if it could not be altered. After some discussion the board promised to bring the recommendation of the shareholders to the auditors.

The resolution was then adopted, and the retiring director and auditor re-elected.

W. T. Henley's Telegraph Works Company, Limited.

The report of the directors states that of the £50,000 additional capital authorised by the extraordinary general meetings held in the spring, the directors limited the present issue to £25,000, reserving the remainder for future needs. The whole of the £25,000 was taken up by the shareholders or their nominees at 60 per cent. premium, enabling the reserve to be increased by £15,000. After negotiations with the local authorities (protracted for several years), Victoria Road, which intersected the works at North Woolwich from east to west, has been legally closed, and its site added to the company's property, which now lies within a ring fence. This great advantage was not obtained without the payment of a sum of £2,000 to the Woolwich Local Board of Health to be applied to some purpose of public utility. The annexed accounts show that during the past year a net profit has been made of £29,584 19s. 7d. After payment of debenture interest and income-tax, and making ample allowance for depreciation of buildings, plant, machinery, &c., there remains £23,936 5s. 7d., making with £14,294 6s. 7d. brought forward from last year a total of £38,230 12s. 2d. From this sum has to be deducted the £500 voted to the directors at the last general meeting, leaving £37,730 12s. 2d. available for distribution. The directors have transferred £7,500 to the reserve fund (in addition to the £15,000 premiums above mentioned), and they recommend the payment of the following dividends, viz.: on the preference shares 7 per cent., including the interim dividend of 3½ per cent. paid on September 1st last. On the ordinary shares at the rate of 12 per cent. per annum, including the interim dividend of 3 per cent. also paid on September 1st last. These payments will together amount to £22,941 0s. 7d., leaving £14,789 11s. 7d. to be carried forward.

Manchester Carriage and Tramways Company.

A special general meeting of this company was held in Manchester last week for the purpose of considering a Bill proposed to be introduced into Parliament in the present session to enable the company to work their tramways by mechanical power, and for other purposes.

Sir J. J. Harwood said that the common sense of the Bill was that outside Manchester and Salford there were a number of local authorities interested in some way or the other in tramways. If they were to determine that their tramways should be worked by electricity, it would be necessary for someone to find the electric current. The authorities would probably not provide it themselves. If they did, he dared say it would be all right for those who were intending to work the tramways. The Manchester Tramways Company had a very large interest in tramways outside the city and outside the borough of Salford, and if it should be found necessary to put down appliances and erect buildings for generating electricity, this Bill would enable them to go to the outside authorities and say that if they did not intend to produce the power for themselves, the company had power to produce it for them, and they could enter into a mutual arrangement with each other. If the authorities, on the other hand, decided to create the power for themselves, the company might try to arrange to use it.

The Bill was approved by the meeting.

The Notting Hill Electric Lighting Company, Limited.

The directors' report states that the expenditure on capital account at the date of the last balance-sheet stood at £99,104 17s. 6d., and during the past year a further sum of £14,079 7s. 10d. has been expended, chiefly accounted for by £11,769 13s. 11d. for mains. The total capital expenditure is, therefore, £113,184 5s. 4d., which is £3,184 5s. 4d. in excess of the capital issued. The balance due at the beginning of 1897 on the preference shares, £3,160, was called up and duly paid during the year, thus making the whole share capital of £100,000 fully paid up.

As announced in the report of 1896, the sum of £10,000 was raised by the issue of 4 per cent. first mortgage debentures maturing in 1931, and redeemable in 1907 at the option of the company by paying the debenture-holder a bonus of 5 per cent. These debentures were issued at the price of 106 per cent., and the applications were considerably in excess of the amount required. In accordance with the debenture trust deed, the amount of these first mortgage debentures is limited to 50 per cent. of the share capital actually issued and paid up. At present, therefore, there are £40,000 of debentures available for additional expenditure. The capital expenditure during the current year is estimated at £7,000, for which further debentures will be issued.

The following table shows the progress of the company:—

				£	s.	d.
1891	Lamps	6,056	Loss	554	18	6
1892	"	9,438	Profit	112	6	1
1893	"	12,153	"	1,481	7	1
1894	"	15,669	"	2,101	17	8
1895	"	20,307	"	3,227	14	10
1896	"	25,716	"	4,736	9	8
1897	"	33,000	"	6,854	1	2

The directors have set aside £1,000 for the depreciation and reserve fund, and have paid a dividend of 6 per cent. on the ordinary preference shares for the year ending December 31st, 1897, amounting to £1,767 14s. 4d. After payment of interest and leasehold redemption a balance is left of £3,884 18s. 1d., out of which the directors recommend that a dividend be declared on the ordinary shares at the rate of 6 per cent., less income-tax, which will absorb £3,871 4s. The sum of £401 16s. 2d., being the premiums received on the issue of £10,000 first mortgage debentures, after deduction of the legal and other expenses, has been written off the preliminary expenses account.

The company has hitherto supplied current at the standard pressure of 100 volts, the price charged being 8d. per unit. In March last the directors decided to supply current at a pressure of 200 volts, at a charge of 6d. per unit, less the usual rebates for long hours. It is not proposed to disturb existing contracts on the old basis, but every facility is given to those desiring to change. A contract has been entered into with the National Electric Free Wiring Company, Limited, which will enable intending consumers to obtain current without initial outlay for wiring or fittings. This only came into force at the latter end of the year, and already 17 houses have been connected on these terms. Very considerable inconvenience has been caused to the engineering staff by the non-delivery of the new and additional machinery ordered in the early part of last year, owing to the labour troubles in the engineering trade. Fortunately the company were able to meet all demands on them without any accident or break-down. Great credit is due to the manager and the staff generally for their care and energy during this very anxious time, which happily is now passed.

Blackpool and Fleetwood Tramroad Company.

The half-yearly meeting of this company was held in Manchester last week, Mr. G. Richardson, deputy-chairman, presiding.

The Chairman said that the balance-sheet showed the company had expended £82,000 on capital account up to January 17th, and they had got a small amount back by the sale of materials. He hoped that at the next annual meeting they would be able to present a satisfactory revenue account from the receipts they would expect to get on the opening of the line. The progress of the works had been satisfactory so far, and they had every expectation that the line would be opened for a great portion of the summer traffic. They had got all the rails down from the Glynn into Fleetwood. The works that were not progressing so quickly were those which the Corporation had in hand. The weather had been very bad, and they had had to contend with it. When the line was finished they would have a tramroad at a very low cost. It was stated that by June the line would probably be open right from Talbot Road Station, Blackpool, to Fleetwood. The meeting authorised the issue of £40,000 debentures.

Telegraph Construction and Maintenance Company.

The report of the directors states that the accounts for the year show a net profit of £61,131, after charging the interest on the debentures. To this sum must be added £39,940 brought forward from last year, making a total of £101,071. From this amount is deducted the interim dividend of 5 per cent., paid July 20th, 1897, amounting to £22,410, leaving £78,661 to be dealt with. Of this sum the directors propose to distribute a dividend of £1 4s. per share, absorbing £44,820, being at the rate of 10 per cent., and making, with the amount already paid, a total dividend for the year of £1 16s. per share, or 15 per cent., free of income-tax, leaving £33,841 to be carried forward to the next account.

Scarborough Electric Light Company.

The sixth annual general meeting of this company was held last week at Scarborough. Mr. George Alderson-Smith, J.P., presided, and in moving the adoption of the report and balance-sheet, said the company during the past year had spent more money than previously, but it had had an effect which was satisfactory. In Scarborough they were handicapped by the price of coal. In Leeds £17,000 of current was produced with a coal bill of £875; in Scarborough the current amounted to £5,300, and the fuel to £1,138. Perhaps a small destructor might be placed on the premises of the company, and as it was only a matter of time before the Corporation purchased the undertaking, it would be doing something towards the future.

Mr. J. B. Simpson seconded, and the report was adopted.

A dividend of 5 per cent. was declared.

Cape Electric Tramways Company.

The statutory meeting of this company was held on Wednesday at Winchester House, Colonel Sir Charles Euan Smith in the chair.

The Chairman, in speaking of the history of the company, said it was formed for the purpose of taking over, as going concerns, the tramway companies then existing at Cape Town and at Port Elizabeth. The company took over these tramways in good working order, and has since made many extensions and improvements, and the whole system is now worked by electric power. Since July 1st, 1897, until the completion of the six months ended December, 1897, the Cape Tramways Company has carried 3,300,000 passengers, which aggregates about 30 times the total population of Cape Town and its suburbs. For July last the traffic receipts showed the gross total of £5,587, but since then the earnings have steadily increased, and the total traffic receipts for December last amounted to £8,815, and January's total shows a further increase, the receipts amounting to £9,400. After giving further details of the system, the chairman said, for the six months ended December, 1897, 869,559 passengers have been carried on the Port Elizabeth system, and they have paid £11,984 in fares. Their receipts for last July—the first month of their operations—were £1,397, and the total receipts for December amounted to £2,734. Having regard to the earnings of the tramways, the directors were able to declare an interim dividend of 2½ per cent. on the last six months' working, notice of payment of which will be given in the usual course.

After further remarks the meeting terminated.

County of London and Brush Provincial Electric Lighting Company.—The directors have decided to recommend payment of a dividend on the preference shares for the six months ended December 31st last, at the rate of 6 per cent. per annum, less income-tax, carrying forward £10,000 to next account. The transfer books and register of members will be closed from 1st to 14th prox., both days inclusive, preparatory to the payment of the preference dividend. The ordinary general meeting will be held on 14th prox., at 2 p.m., at Winchester House.

Buenos Ayres and Belgrano Tramways Company.—The transfer books will be closed on and after to-morrow for repayment at par with accrued interest on 1st prox., of the stock held by proprietors who have not accepted the option of conversion into the 5 per cent. debenture stock of the Buenos Ayres and Belgrano Electric Tramways Company, Limited.

Stock Exchange Settlements.—The Stock Exchange Committee has (1) appointed Wednesday, March 2nd, a special settling day in Electric Construction Company, Limited.—£111,100 4 per cent. perpetual first mortgage debenture stock, and has ordered same to be officially quoted.

Telegraph Construction and Maintenance Company.—The transfer books will be closed from the 21st inst. to the 1st prox., inclusive, preparatory to the payment of dividend.

British Electric Traction Company.—The letters of allotment and regret in the issue of 10,000 6 per cent. cumulative preference shares were posted last week.

TRAFFIC RECEIPTS.

The Bristol Tramways and Carriage Company, Limited.—The receipts for the week ending February 18th, 1898, were £2,399 2s. 8d.; corresponding period, 1897, £2,088 7s. 11d.; increase, £310 14s. 9d.

The City and South London Railway Company.—The receipts for the week ending February 20th, 1898, were £1,051; week ending February 21st, 1897, £1,044; increase, £7; total receipts for half-year, 1898, £8,565; corresponding period, 1897, £8,717; decrease, £152.

The Dover Corporation Electric Tramways.—The receipts for the week ending February 19th, 1898, £104 13s. 9d.; total receipts, February 19th, 1898, £747 17s. 11d.

The Dublin Southern District (Electric) Tramways Company.—The receipts for week ending Friday, February 18th, 1898, were £385 7s.; corresponding week last year, £484 1s. 8d.; decrease, £99 14s. 8d.; passengers carried, 65,874; corresponding week last year, 73,303; aggregate to date, £2,863 12s. 8d.; aggregate to date last year, £2,947 10s. 8d.; decrease to date, £83 18s.; mileage open, 8 miles.

The Liverpool Overhead Railway Company.—The receipts for the week ending February 20th, 1898, amounted to £1,320; corresponding week last year, £1,320.

The Western and Brazilian Telegraph Company, Limited.—The receipts for the week ending February 18th, 1898, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £2,819.

INSTITUTION OF ELECTRICAL ENGINEERS.

On the Manufacture of Lamps and other Apparatus for 200-Volt Circuits. By G. Binswanger Byng, Member. (Paper to be read February 24th, 1897.)

In the progress of electrical industry, manufacturers have become accustomed to sudden demands arising from a discovery or a successful experiment, and I propose to deal with apparatus which manufacturers are called upon to make to meet the requirements of the latest innovation—*i.e.*, the distribution at a potential of 200 to 230 volts. Central station engineers have thus arranged their three-wire system, relying upon makers to successfully alter lamps and minor fittings incidental to such a change. Their expectations have been fulfilled in a measure only. The ultimate success of the high-pressure system will depend largely upon the verdict of the consumer, and he will give it in its favour only if his fittings, in points of efficiency, economy, safety, convenience, and appearance, approach the standard which he can obtain by means of the lower voltage system.

It is, therefore, of importance that the central station engineer should assist the manufacturer to arrive at such perfection. His instructions, so far, have hardly gone beyond the demand to supply him with fittings to conform in appearance to the 100-volt system. It is true each central station has issued rules, but they are of little help to the manufacturer, and their very disconformity shows that there is neither unanimity nor correlation of ideas between the engineers in charge.

What is wanted is to have a thorough interchange of opinion of engineers, contractors, and manufacturers. The latter would then know theoretically how far they may satisfactorily depart from the present practice, and thus save much time and money in adventitious experiments; and this also might tend to produce some degree of standardisation—much to be desired in the interest of all who have the success of the new system at heart.

With this object in view I bring this paper before you, and I think I can best serve the purpose by describing the chief appliances now upon the market, or under manufacture at my works, pointing out the existing deficiencies, and giving you my views upon the attainment, as far as possible, of higher perfection.

Incandescent Lamps.

Most important in connection with this subject is the incandescent lamp.

The lamp manufacturers have been compelled to supply 200-volt lamps at a given candle-power and efficiency, in the same size bulbs as are used for 100-volt lamps. With flashed carbon the manufacturers meet with the great practical difficulty of properly disposing their long, thin, 200-volt filament in the same space as their shorter and thicker 100-volt filament, and therefore most of them solve this problem by resorting to a filament of much higher specific resistance than would be given by the flashing operation.

Unflashed Filaments.—Such a lamp is ready to the maker's hand by simply taking his ordinary carbon filament as it exists before being flashed—that is to say, before it is reduced by a fresh layer of carbon being deposited on the surface of the original filament.

The higher specific resistance of an unflashed carbon enables one to easily get over the difficulty of size of bulb, as such a filament will give the necessary resistance by taking a shorter length. Such filaments have also a greater emissivity, owing to the darker and rougher nature of their surface than that of flashed filaments; consequently they require a less amount of surface per candle-power, and therefore the mass of an unflashed filament, at a given candle-power and efficiency, is less than that of the flashed filament.

The filaments of high-voltage lamps largely used to-day are therefore, in other words, faster converters of energy into heat and light than flashed filaments of the same candle-power and efficiency, although the watts supplied to each be the same.

On comparing the behaviour of such 200-volt lamps with that of 100-volt lamps, the roughest of tests shows that there is a far more rapid falling off of candle-power during life with the former than the latter. At the same time the efficiency of an unflashed lamp decreases in a given number of hours by a far greater percentage than is the case with the flashed lamp. Mr. Robertson has made a series of life and efficiency tests on high-voltage lamps. They show that in the average unflashed 200-volt 16-C.P. lamp the percentage loss of candle-power in 600 hours is about 42 per cent., and the average drop of efficiency is about 35 per cent.

These two quantities seem to cover the chief practical merits desirable in an incandescent electric lamp—*i.e.*, the lamp which has the best percentage retention of original candle-power during its life, together with the best average percentage retention (or increase) of original efficiency during its life.

These tests show that these most desirable points, which have been worked on diligently for the last 13 years, have had to be thrown on one side in order to bring about the possibility of using the same sized bulb for a given candle-power at 200 volts as at 100 volts.

Tests of the behaviour of unflashed high-voltage lamps show that such lamps sometimes increase in candle-power during the first 100 hours or so. This also happens with badly carbonised or badly flashed 100-volt lamps (noted by Prof. Ayrton in some of his recent lamp tests), owing to the initial lowering of their resistance in consequence of their not having been properly carbonised in the first instance; and this is often accompanied by a great alteration in the character of the surface (emissivity) of the filament. The carbonising or baking progress is therefore still going on in the lamp, and the two above-mentioned changes coming together mask the fact that a great deterioration of the filament has taken place; but a period is quickly reached when this fact is no longer masked. This period is when there is no further decrease of resistance; but the surface deterioration still goes on, and thus soon brings about a large percentage fall of candle-power, and on the slightest increase of voltage there is now a tendency to increase resistance. These changes seem to be initially owing to the fact that the (unflashed) high specific resistance carbon is far more volatile than is the case with a good flashed carbon.

A microscopical examination of a flashed and unflashed filament, after each has been running 100 hours, shows that the surface of the flashed filament is still quite smooth and shiny, whereas the surface of the unflashed filament has become very dull, sooty, and often full of small pit-holes. These pit-holes and soot form a large increase of surface; which therefore increases the emissivity of the filament, and consequently lessens its candle-power, as the watts supplied keep the same.

The property of an unflashed filament becoming so rapidly less efficient (increasing in watts per candle-power) acts as a preservative, because the increased emissivity lowers the temperature. This lowering of temperature decreases both the tendency to volatilise, and also to further great change of resistance. This power of self-preservation leads to such a filament giving some satisfaction to the general public, for the latter is satisfied when it obtains a good average, or sometimes an excessively long-life lamp; but this is a very false economy, as it is only purchased by a very great falling off in actual efficiency.

Mr. Robertson's experience with carbon filaments seems to point to the fact that *it is impossible to obtain a carbon filament of high specific resistance without its being accompanied by at least the defect of greater volatility*. In other words, the lowest specific resistance carbon is the best, because it is less liable to evaporation, and therefore it gives the best retention of original candle-power and efficiency, and it is also mechanically stronger.

The specific resistance of many of the present types of 200-volt lamps is about 3,500 to 5,000 microhms per cubic centimetre, whereas it is easy to obtain flashed carbons whose specific resistance is as low as 2,400 microhms per centimetre; and even as low as 300 is possible, but not practicable.

Gases.—Another important consideration to bear in mind as to whether the high or low specific resistance carbon is the best, is that the high specific resistance filaments retain their occluded gases in a far more persistent degree than is the case with the low specific resistance flashed filaments.

It is probable that the occluded gases arising from the carbonisation of the filament are, by means of the flashing process, driven off to a large extent; and, in addition, the more dense and impervious nature of the flashed surface prevents the filament from absorbing the gases during its subsequent handling or treatment. This absorption is a property possessed by all carbon bodies in some proportion, varying with their density.

This greater power of unflashed carbon to absorb gases and to retain what it has absorbed, than is possessed by flashed carbon, leads in many instances to sudden deterioration of the vacuum in a finished lamp, accompanied by short-circuiting as soon as the pressure and the condition of the residual gases in the bulb has reached its most conductive point.

The consensus of opinion at the present day of the average types of high-voltage lamps undoubtedly points to the fact that a large percentage are expected to short-circuit as soon as they are put up, and I have heard several engineers say that they expect about one in twelve to go in this way.

From these causes, and others relating to the treatment of filament pointed out above, there seems to be no doubt that the average 200-volt lamps have a shorter life than 100-volt lamps. The above experiences have led Mr. Robertson to design all high-voltage lamps that are not restricted by size with well-flashed carbon filaments, and such lamps compare favourably with lower voltage lamps.

Horizontal Burning.—Another question which is very important in considering 200-volt lamps is that of horizontal burning, and contractors should take special notice of this. There is no doubt whatever that almost all the present-day 200-volt lamps are only suitable for burning in a vertical position. As soon as any other position is adopted defects become prominent. The long thin filament soon drops on to the bulb and cracks it. Also electrostatic attractions, owing to higher voltage, cannot be resisted by the long thin filament, and this is an additional cause of the filament approaching the bulb.

The effect of electrostatic attractions on long thin filaments is even noticeable with lamps burning in a vertical position. Such lamps have to be designed with the object of making their filaments more rigid, and to be thus able to withstand the effects of gravity and electrostatic attractions exerted by the charge on the bulb; and this is the chief point which makes high efficiency 200-volt lamps so difficult to produce. There is, therefore, a tendency, in trying to avoid the defects just mentioned, to make 200-volt lamps as low in efficiency as possible.

Leading-in Wires.—Another fault that exists with the bulk of the present forms of high-voltage lamps is that, owing to the same size bulb being retained, no greater separation can be given between the leading-in wires of the lamp. This is a special difficulty with high-voltage lamps which contain two filaments, as in this case the same size cap is used, and four wires are passed through the sealing point instead of two, and they are therefore more crowded together. This question of distance apart of leading-in wires is a vital one, both in the manufacture of the lamp and in its after use. In the case of unflashed carbons this becomes a still greater defect, owing to small distance combined with probably greater gaseous emanation.

The higher the voltage, the sooner are these defects made manifest. Even with 100-volt lamps there is, under certain conditions, a tendency for current to jump across from pole to pole, owing to the remanent gases in the bulb attaining a high state of conductivity. The greatest conductivity of the remanent gases which lead to sudden short circuiting appears to be when the pressure is about 0·01 mm. But, by reason of a continued discharge taking place in all lamps, there seems to be a tendency for the residual gaseous molecules to arrange themselves in a straight path between each pole. Through such a path discharge will take place even in a better vacua than 0·01 mm.

This leakage current (sometimes called the "Edison effect") which leads to short circuiting is very prominent during manufacture of high-voltage lamps, and to avoid it, greater care is required as the voltage increases.

If the size of a bulb for a high-voltage lamp is to be restricted to the present dimensions, there is no doubt that the best lamp would still be that which has a single filament, were it not that other vital questions step in.

Electrostatic effects also increase with the voltage, and several most promising patterns of lamps, from all other points of view, have had to be put on one side on this account.

As to the best forms of cap for high-voltage lamps, preference will naturally be given to those in which the poles can be kept furthest apart.

If a B.C. or E.S. cap were on a larger scale, there is no doubt that considerable benefit would accrue. The simplest holder, with the least moving parts and for always making the best contact, is undoubtedly the Edison screw, which, in the cases of excessive vibration, can be made with a locking device.

The slightest want of insulation in the cap between the poles eventally leads to a large leakage current between them or the cap and one of the poles, and in many cases this is suddenly established to such a large degree as to result in the complete fusion of the lamp cap, and sometimes the holder. In such cases a non-metallic lamp cap seems to offer great advantages, and has, in my experience, removed complaints on this score.

Standard Voltage.—From a lamp maker's point of view, a fixed standard of voltage and efficiency would only lead to an increased cost in manufacture, and the present practice of varying efficiencies with voltages, running in the case of low-voltage lamps from 95 to 120, and in the case of high-voltage lamps from 200 to 230, tends to keep the lamp at a lower cost than if these efficiencies or limits of voltage were more restricted.

On the other hand, voltages which lie outside these limits are a source of great expense to the manufacturer. It would, therefore, tend to cheapen lamps if a standard of voltage were adopted which lay exclusively between the above or even smaller limits, but at varying efficiencies.

Combination Filaments.—In order to get over the difficulty of size of bulb, &c., many filaments (beyond the unflashed pure carbon derived from cellulose in some form) have been introduced which have a high specific resistance. This can only be obtained by using a less dense form of carbon than has hitherto been found most satisfactory in low-voltage lamps.

A form of high specific resistance filament that has been tried is where the carbon has been admixed with various oxides, borates, and silicates of the earths. In addition to mixtures, electrolytic and chemical deposits of these bodies on the surface of carbon have also been tried; but, although it is a simple matter to obtain baked carbons containing these bodies, either incorporated with the carbon or on the surface thereon, it is quite another matter to obtain a finished lamp containing these bodies in a form to be of any practicable use. The difficulties met with are apparent as soon as the lamp is incandesced while undergoing exhaustion.

If such lamps be incandesced to a temperature exceeding about 5 watts per candle-power, there is a gradual separation by evaporation of these bodies from the carbon, and their resulting deposition on the surface of the lamp bulb.

The temperature of incandescence of the filament, in order to obtain any advantage which might be derived from the "luminescence" of the rarer earths is apparently greater than 5 watts per candle-power; and as, as above stated, it has been found impossible to so evacuate a lamp as to leave any of the "luminescent" bodies incorporated with the filament at temperature higher than 5 watts per candle-power, the object sought for is consequently defeated.

From the above, it seems that, with our present knowledge, the best form of 200-volt lamp is that which has a well-flashed low specific resistance pure carbon filament in a large bulb, with a well-insulated moisture-proof cap allowing the poles to be placed at a reasonable distance apart. It should consist of a single filament, and be so disposed in the bulb that it can withstand the disturbing effects of gravity and electrostatic charges on the bulb.

I wish to mention here that my co-director, Mr. Robertson, has given me great assistance in the remarks I have made upon lamps.

Switches.

I come now to the matter of adapting switches, wall plugs, ceiling roses, lampholders, and minor fittings.

I do not apprehend any difficulty in changing existing types from the present standard of use to conform to the higher standard, yet maintaining the same appearance and size, and, when sufficiently in demand, approximately the same cost. The chief alteration will be in the increased break, and better insulation of the two poles. In smaller articles, such as combined switches and lampholders, the difficulty, if any, is more apparent. A discussion bearing upon the subjects involving the use and construction of double-pole switches, length of break, standardisation of terminals, position of fuses, the carrying capacity of contacts, &c., would be, to my mind, of great value.

(*To be continued.*)

TESTS OF THE SYNCHRONOGRAPH ON THE TELEGRAPH LINES OF THE BRITISH GOVERNMENT.*

By ALBERT CUSHING CREHORE and GEORGE OWEN SQUIER.

(*Concluded from page 244.*)

Under the latter condition the synchronograph and Wheatstone receiver sent 666 words per minute, corresponding to 266·4 complete waves of current per second. The coils of the receiver were joined in parallel, and no condensers were used. Voltage, 175. In this line, where the mechanical limit of the Wheatstone receiver is reached before the speed is limited by the total value of K R of the line, it is seen how the perfect regularity, equality and shape of the sine waves materially increased the speed of the Wheatstone receiver.

With the synchronograph and chemical receiver the alternator was run higher than before, until a rate was attained of 1,446 single impulses per second.

With the line earthed the Wheatstone transmitter and receiver sent 360 words per minute with a voltage of 100. The synchronograph and Wheatstone receiver sent 540 words per minute, voltage 200. The receiver coils were in parallel, and a condenser was shunted across the coils. No limit was obtained in this experiment.

The longest line as yet tested, of 1,097 miles, was then made up, from London to Aberdeen *viâ* York and Edinburgh, and return *viâ* Glasgow and Leeds. A portion of the line north of Edinburgh was iron wire upon the same poles, going and returning. With no earth the total K R was 65,304.

Wheatstone transmitter and receiver sent over this line 185 words per minute, voltage 100. Synchronograph and Wheatstone receiver sent over this line 540 words per minute, voltage 215. Synchronograph with chemical receiver sent at frequency of 723 or limit at which it was safe to run the alternator. This result was higher than expected from the approximate law indicated by the preceding trials, and a reason for this was sought. The line was broken at Aberdeen, and records were still received. It was then restored at Aberdeen and broken at Glasgow, when, as before, no record was obtained. The cause of this was thought to be the inductive effect of that portion of the line beyond Glasgow, where the iron wires going and returning were unavoidably upon the same poles.

With an earth connection the total K R was 261,215, and the Wheatstone transmitter and receiver sent over this line 46 words per minute, voltage 100.

The synchronograph and Wheatstone receiver sent over this line 135 words per minute, voltage 85, coils in series $L = 3·46$, condenser of 5·75 microfarads shunted across coils.

The Transmission of Intelligence in Great Britain.

One of the reasons for going to England was to become conversant with the method of conducting the telegraph and telephone business in conjunction with the general postal service in a country where these three departments are under the control of the Government.

In the prosecution of this, as in the experiments themselves, every facility was afforded by the Government officials.

It is recognised that to draw correct conclusions upon the general subject of the transmission of intelligence requires men of experience in dealing with such matters, who give the subject their attention for a considerable period. Some of the principal facts, however, seem to be so clearly defined in their relation to others that we feel warranted in making some observations thereon.

The telegraph revenue and expenditures have increased with approximate uniformity. In 1872 the revenue was about $18,200,000, and the expenditure about $14,500,000, while in 1896 the revenue was $69,700,000 and expenditure $70,500,000. These two items have nearly coincided during 25 years, showing that the telegraph business is conducted on the whole to meet the expenses only and leave no profit. In some years the expenses are greater than the revenue, and the account shows a deficit. This has been the case for the last five years, but it has been gradually decreasing for three years, and in 1896 was only $168,000.

The number of telegrams forwarded from telegraph offices in the United Kingdom in 1871 was 9,850,177, and in 1896 was 78,839,610. In 1896 the ratio of the number of letters to telegrams was 18·5.

The charge for transmitting ordinary telegrams is a half-penny, or one cent per word, including the address, independent of the distance. The minimum charge is 6d., or about 12½ cents. The telegraph is used to a much greater extent for transmitting news in England than in any other country; for instance, in 1896, 5,915,646 telegrams were transmitted at the press rates for newspapers, clubs, &c. The average weekly number of words contained in these telegrams was about 13,650,000. The average length of each telegram is therefore 120 words. The explanation of this is found in the reduced rate given to the press after 6 p.m., which is at present but 6d. per 100 words. This press matter is handled almost entirely by the Wheatstone automatic system, automatic telegraphy being more advanced than in any other country in the world. There are as many as 447 sets of Wheatstone instruments in use in Great Britain, and for press messages pneumatic perforators are used, and a number of duplicate strips are prepared at once, and thus the same press news may be sent out on eight or nine different lines from London at the same time. Many of the lines, which are ordinarily operated by hand, are equipped with Wheatstone instruments. These are switched in whenever the traffic for the particular line becomes too great for hand transmission. They are also much employed for temporary lines where an unusual volume is to be handled in a short time, such as in sending the enormous amount of racing and sporting news required.

The telephone service in England is not entirely under the control of the Government. The trunk lines are so controlled and operated, leaving to private companies the service in local districts. Some of these trunk lines were transferred to the Government on March 25th, 1896, by an agreement with the National Telephone Company.

In a country where the three great branches of intelligence transmission, the mail, the telegraph and the telephone, are under one management, special advantages to the people are obtained which are not given when these departments are separated. In England messages may be telephoned:

1. For transmission over the postal telegraphs and delivery as telegrams.
2. For delivery as express letters.
3. For transmission and delivery as ordinary letters.

The telephone may also be used for obtaining the services of Post Office express messengers.

As indicating the increased demands for communication between England and the Continent, the following extract from the last report of the Postmaster-General is given: "The large increase in the number of telegrams passing over the Government cables to the Continent, and in the number of conversations on the telephone circuits between London and Paris, has rendered it necessary to consider the advisability of improving the means of communication. With the cordial co-operation of the German post office, experiments were made with a view to improving the carrying capacity of the cables to Germany by the method of duplex working, which has been employed with success on some of the Anglo-French cables; but, owing to the greater length of the Anglo-German cables the results obtained were not sufficiently successful to justify the adoption of the system for practical working. Arrangements have now been made for the laying of three additional cables to the Continent, two to France, and one to Germany. These cables, each of which will contain four conductors, will afford a much-needed relief to the traffic; and it is expected that this new cable to Germany will prove suitable for duplex working."

A YEAR'S BOILER EXPLOSIONS.

When the Boiler Explosions Act came into force some years ago the Board of Trade reports on explosions were looked on by experienced men as very amusing documents. "Iron bound in red tape" might have been humorously applied to these reports and to the inspectors responsible for them. How men supposed to have experience of steam boilers could make such reports was a matter that puzzled all of us, and it does not appear that the annual report—the 15th—is much better than of old. In the 12 months the Board of Trade rakes together 80 explosions, causing 27 deaths and 75 injured, a reduction on the average of the whole 15 years, though very near the average. Great Britain possesses the best record, we should imagine, but our allowable pressures are low, and the marvel is that explosions in the United States, where pressures are so very liberal, are not far greater than they are. Only 23 explosions out of the 80 were held to require formal investigation. We must add that very paltry matters constitute a boiler explosion in the eyes of the Board of Trade. We do not think they have included broken glass water-gauges, but they came very close to this and included blown fusible plugs.

Looking through the list only 12 explosions appear to be attributable to ignorance or neglect of attendants, which would seem a powerful argument against the folly of licensing attendants by examination. In this day we are examined to death. Educate—by all means educate—but do not shut out plain horse-sense as the Americans term it by examining. As well examine a sea captain in drawing-room manners because he dines with ladies at the saloon table as examine a boiler attendant to three places of decimals.

Steam pipes, both of copper and cast-iron, continue to give way. We cannot understand why copper should still carry so much credit. Either brazed or solid it does not seem so very reliable. The report advocates lap-welded wrought-iron pipe. It is advocated to hoop them or wire them when of copper. The *Engineer* would hoop or wire all pipes say at 2 inches intervals. If a seam opened it could not be longer than 2 inches. Pipes which burst seem

* Abstract of a report to the Postmaster-General of the United States, read before the Franklin Institute, January 19th, 1898, and published in the *Electrical World*.

so readily to tear for some feet and let out huge volumes of steam. A 2-inch hole gives the men a chance of escape and time to shut off the boiler stop valve. Why the Board of Trade should so insist on the hydraulic test is a marvel. The hydraulic test is something of a fool's test and cannot displace inspection or safeguards. Boilers tested to-day by hydraulic pressure are more than likely to pop off next day—being never strengthened by the test—often an excessive one. In New York policemen go round with a van and a pump, damaging boilers by pressure and giving safety certificates. Steam piping seems to have belonged neither to boilers nor to engines, hence the neglect to manufacture it properly and to put it in place properly with provisions against strains and against rigidity.

Steam piping ought to be as carefully laid out as the engine, and every proper provision made for its drainage. So many recorded explosions are due to that wasteful class of small vertical boilers, that we may well anticipate a considerable reduction of the now apparently irreducible annual minimum as soon as electrical power transmission has wiped out the need for small verticals. Of the 23 formal investigations there were nine of vertical boilers, three horizontal, one Rastrick, and four locomotive type. Obviously there is a field for electricity in abolishing some of the nine verticals. Next year the average will be much the same. Other nine verticals are getting ready to fill next year's bill. Doubtless one of them has gone already.

CONTRIBUTIONS TO THE THEORY OF ALTERNATING CURRENTS.*

By W. G. RHODES, M.Sc. (Vict).

[ABSTRACT.]

THIS paper is divided into two parts. Part I. deals with a method of finding the steady values of alternating currents in any circuits or systems of circuits, without having to perform integrations of differential equations which may be somewhat complicated.

It is assumed, however, that the electromotive forces and electric currents can be represented as simple sine (or cosine) functions of the time.

The method consists in applying the fact that if a simple harmonic function is differentiated twice in succession the result is proportional to the original function. By the application of this principle the determination of the steady values of the currents is reduced to solving a set of simultaneous *simple* equations.

After introducing the method by solving some simple problems, it is applied to the following:—

(a) The determination of the equivalent resistance, R, reactance and impedance, I, of a parallel circuit of n branches, taking into account mutual induction, when each branch may contain resistance, capacity, and self-induction.

The result is written

$$R = \frac{A_0 C}{C^2 + p^2 B^2}, \quad L = \frac{A_0 B}{C^2 + p^2 B^2}, \quad I = \frac{A_0}{\sqrt{C^2 + p^2 B^2}},$$

L being the equivalent self-induction, where A_0, C, B are certain functions of the resistances, self-inductions, capacities, and mutual inductions of the several circuits.

(b) The determination of the currents in the n circuits of an air core transformer having one primary coil and $n - 1$ secondary coils.

In addition to solving the problem, the conditions for resonance in the primary circuit are obtained and discussed, and special attention is given to the case of a transformer having only one secondary coil.

(c) The determination of the outputs of n alternators working in parallel on a non-inductive external circuit.

PART II.

This part is devoted to the consideration of the effects of higher harmonics in E.M.Fs. and currents on the values of the impedances and reactances of circuits.

The problems considered in Part I. are again discussed on the assumption that the impressed potential difference is of the form

$$E = E_1 \sin(p\,t - \theta_1) + E_2 \sin(2\,p\,t - \theta_2) + \ldots + E_m \sin(m\,p\,t - \theta_m).$$

It is also shown that periodic E.M.Fs. and corresponding currents can in all cases be represented by simple sine curves having the same root mean square values, and suitable phase positions depending on the time constants of the circuits and on the periodicities of the harmonics present.

* Communicated to the Royal Society by Arthur Schuster, F.R.S. Received January 4th—Read February 10th, 1898.

ANTHRACITE TESTS.

L'Industrie Electrique reports some tests made at the central station in the Place Clichy, Paris.

Numerous tests of all kinds of fuel have already been made with a view to smoke prevention. Coke has been tried and abandoned, both because of high price, and because its acid fumes damaged the tubes of the boilers. A municipal commission, which was appointed to consider the subject, has not yet rendered a report. Recently, however, M. A. Lalance has communicated to the Société Industrielle de Mulhouse, certain results obtained with English anthracite at the station in the Place Clichy. He had previously tried the Langer smoke preventer, so much used in Austria, and had furnished six boilers with this apparatus, using a coal named St. Charles from the Charleroi basin, which when considerably dampened, gave but little smoke, and no further complaints were made, but the mechanism necessary was delicate, and wear was so rapid as to necessitate regulation every second or third day. Searching for other and better means, he heard of the use of anthracite in London and arranged two boilers with grates of Richard's type, perforated with conical holes, and with a draught aided by three steam blowers in each closed hearth-pit. These grates are, in fact, simply perforated plates, and enable fine anthracite to be burned. The changes necessary to be made to a boiler are trifling. The fire thickness should be 3 to 4 centimetres. It is found easy to maintain pressure by draught regulation. Cardiff anthracite is described as burning quite smokelessly, and the management of the fires is easy, as with coal, and no dust is made.

The tests made by M. Heckel were for the purpose of seeing whether the numerous advantages of the coal were in any way counterbalanced in cost. The tests extended from April 5th to 16th last, and the arrangement of the plant was such as to permit either of two generators of 350 kw. each to be driven with steam from two boilers with the Langer smoke preventer, or from the two boilers burning the anthracite. No note needed to be made of water used or evaporated. So much electricity was manufactured, and so much fuel in each case was needed to do this. In fine, St. Charles coal, costing at works 28 francs per ton, was burned on the Richards grate, and anthracite, costing 34 francs per ton, was also used. The 34 francs was made up of cost, of octroi 7 francs 20 cents, and of cartage 3·50 francs.

The mean of three anthracite tests showed a fuel cost of 7,787 centimes per kw.-hour. The mean of three tests with the St. Charles coal on ordinary grates and with the smoke preventer gave a cost of 7,382 centimes per kw.-hour, and two tests with the same coal on the Richards grate with forced draught showed a mean cost of 7,458 centimes. The difference is not large, and evidently weight for weight the Cardiff coal is the better fuel, and if its price could only be reduced to 32 francs, it would stand even as to cost, and would besides have all its other advantages. Our contemporary would like to see a direct service from Cardiff to Paris, which would enable Cardiff anthracite to be not only the most pleasant fuel, but also it would show a small first cost economy.

THE DIESEL OIL ENGINE.

THE *Engineer* translates from *Zeitschrift des Vereines Deutscher Ingenieurs* a description of Diesel's oil engine or Rational Heat Motor. Diesel claims that his motor better utilises the heat supplied to it than any other motor. Thus while the best saturated steam engines give 12 per cent. efficiency, small condensing engines give only 5 per cent., which is not encouraging. This, however, is quite an unfair way of stating the case, and takes no account of the thermodynamic possibilities on which basis progress of steam engineering has not been so very hopeless. In a steam plant the boiler efficiency is 80 per cent., the engine cannot work without loss, and so a triple expansion Sulzer engine plant of 700 H.P. with steam superheated to 350° C., shows 13 per cent. mean heat efficiency, and this cannot be much extended for steam engines, for only 30 per cent. of the heat received by an engine can theoretically be turned to work.

The great drawbacks to steam are the heat lost in its generation, the low theoretical efficiency, a defect which cannot possibly be amended, the sensitive nature of steam in respect of its easy condensation, and the influence on it of its immediate surroundings as the cylinder walls.

The object of the author's research has been to improve the utilisation of heat. First, he experimented with ammonia at a large range of temperature, and found that wide temperature ranges required wide ranges for pressure also, to allow suitable expansion. This conclusion he applies to all vapours, for otherwise the vapour would be superheated at exhaust, and some portion of heat is thereby wasted. He considers it impossible, theoretically, to determine the pressures necessary to utilise the superheat, but approximates it at 50 to 60 atmospheres, and ammonia being difficult to handle at such pressures, air was tried as a simpler agent, and the same theoretical results were obtained and conclusions drawn. The air was first treated in closed vessels, with heat applied and withdrawn externally, but it became clear that the air could be compressed, and heat generated in the cylinder itself, as already performed in other internal combustion motors. In what he claims as a new process of combustion, Diesel emphasises the difference between the temperature of ignition and that of combustion. The temperature of ignition is lowered by pressure. Hitherto the temperature of combustion, which is higher than that of ignition, has been produced after ignition—by and during the process of combustion. This seems too obvious, at first sight, to gainsay, but Diesel has evolved a new system of combustion, which he calls "rational." It demands four essential conditions. First, the temperature of combustion must be produced before combustion, and independently of it, and it must be produced by the mechanical compression of air. This is seen to be in conformity with Carnot. Secondly, the air must be adiabatically compressed, and not isothermally, as demanded by Carnot, thus attaining to the temperature of combustion at 40 or 50 atmospheres—a much lower pressure than if compression be at first isothermal. By avoiding the theoretical 100 to 200 atmospheres required in the theoretical cycle, an impossible working cycle is replaced by a possible one. The air being now at the temperature of combustion, the combustible is injected into it in such manner that the heat developed by the combustion is at once converted into work. The piston, in fact, moves with the fuel ignition, and combustion adds very little or nothing to the temperature in the cylinder.

The fourth essential is somewhat contrary to preconceived ideas, which have been that excess of air for combustion should be minimised. Diesel's method, however, demands a large excess of air, but an amount carefully determined for each fuel. To carry out his system, Diesel proposed a four-cycle process, worked with three cylinders; the two outer ones being motor and combustion cylinders, and the inner one being for compression, expansion, and exhaust. The outer cranks are at 180° from the middle crank. Air is drawn into the central cylinders, partially compressed, and sent to the receiver. The two plunger pistons then draw in air on the first down stroke, and deliver it compressed to the requisite pressure on the up-stroke. On the next down stroke the combustible is admitted, and burns as the piston descends. Powdered coal has been proposed, but pulverised oil has been alone found practicable. Admission of combustible only lasts one quarter of the stroke, after which expansion occurs, exhaust then takes place into the central cylinder, the piston of which is driven down and compresses the air beneath it. On the return stroke the exhaust of this cylinder escapes to the atmosphere; thus the whole process is completed in two revolutions of three pistons or four strokes.

It is claimed that the boiler efficiency is equal to unity, the possible theoretical efficiency is from 50 to 70 per cent., and thus double that of the steam engine; the gases produced do not condense like steam—some of them must do, for they are steam—and there is no loss of heat in passages and pipes; but the mechanical efficiency must be lower, because of the high compression, and this has been argued to more than outweigh the advantages. But Krupp joined the supporters, and a 12-horse engine was made to test the question, and subsequently another and improved engine of same size, and as a result of the tests made, a 20-horse engine was next made, but it had a single cylinder only, and generally resembled an ordinary petroleum engine, being single acting and water jacketed; this latter being a source of loss not yet overcome, or apparently hoped to be overcome. This engine has undergone many tests by representations of Krupp, Sulzer, and Deutz, and by Profs. Schroter, Gutermuth, Sauvage, and others, and all seem to agree that the new motor has the highest efficiency of any motor, the efficiency being double that of steam and half as much again as other internal combustion motors.

The oil consumption is only ½ lb. per brake H.P.-hour under normal working conditions. An advantage is that no explosions are missed and combustion is complete so that no dirt collects on the internal surfaces. Nor is there ignition apparatus of any kind. The trials by Profs. Schroter and Gutermuth show a heat efficiency per I.H.P. of 34 to 35 per cent. It thus appears that Diesel's views have been confirmed, and the motor is a solitary example of an engine built to theory and living up to it, whereas in other things the theory is deduced after the practical man has shown a thing to be possible.

The exhaust gases were practically invisible and odourless, proving complete combustion, and their analysis showed for full power a mean air excess of 26 per cent., and at half power of 160 per cent.

The thermal efficiency is found to increase with lesser powers, and the economic efficiency only fluctuates between 22 and 16 per cent. The following table may be of interest. It is a summary of tests made in February last, and embraces four trials. The tests were made in Augsburg:—

Diameter of motor piston	...	9·8 inches.
Stroke " "	...	15·7 "
Diameter of air pump	...	2·7 "
Stroke " "	...	7·8 "
Calorific value of oil ...	...	18·370 B.T.U. per lb.

THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.

(*Concluded from page* 238.)

"A New Electrode for Use with the Static Machine," was presented by Dr. Lucy Hall-Brown, New York, who sent a communication on the subject. An efficient spray current could be administered by means of a wire brush on a handle, consisting of about 400 fine steel wires arranged like a small whisk.

Dr. Bergonié, of Bordeaux, France, sent three short communications, entitled:

(*a*) "A New Localising Electrode to Prevent the Diffusion of the Current."

(*b*) "Palliative Treatment of Tic Douloureux of the Face."

(*c*) "The Action of the Röntgen Rays on the Vitality and Virulence of Koch's Bacilli in Cultures."

These were translated and read by Dr. F. Schavoir, of Stamford, Conn.

The localising electrode consisted of eight or 10 narrow electrodes, connected alternately with the positive and negative poles. The current must have an extremely high intensity in order to become diffused.

In the treatment of tic douloureux, he uses a large electrode on the face, and an indifferent electrode to the dorsal region. A continuous current of 50 volts and 30 to 50 milliamperes is employed, and the periods of ascension and diminution last from seven to 10 minutes. The maximum intensity should be maintained for at least 20 minutes. As the cases had been kept under observation for several years, he could say positively that the treatment always brought relief from intense pain, and sometimes after a considerable time caused its permanent disappearance.

The author described in detail the manner in which his investigations into the action of the Röntgen rays on the tubercle bacilli had been conducted, and concluded, from his experiments, that the exposure of the culture for one hour did not destroy the virulence of the culture, but retarded its evolution, and also that the vitality of the cultures was not modified.

"Report of the Committee on Electric Light for Diagnosis and Therapy, and the Röntgen X Rays," by Dr. F. Schavoir, Stamford, Conn. With the static machine the rays produced were far more penetrating and steady, and the radiographs could be taken with a much shorter exposure than by other means; many and great improvements had been made in vacuum tubes, and that a marked increase in transparency had been secured in the fluoroscope by the substitution of barium platino cyanide for the tungstate of calcium.

The President read his address, which briefly reviewed the history of the Association, and suggested several changes which would increase the value and usefulness of the Association, and lessen the work of the executive. On motion of Dr. Charles R. Dickson, it was resolved that the Executive Council be directed to consider the suggestions contained in the President's address, and also the matter of the revision of the constitution and bye-laws; that their report be mailed to the members at least one month prior to the next meeting, and that notice of such amendments is now given.

On motion of Dr. R. J. Nunn, it was decided to hold the eighth annual meeting in the City of Buffalo, N.Y., and the second Tuesday in September and two following days were chosen as the date.

The following officers were elected for the ensuing year:—

President.—Dr. Charles R. Dickson, of Toronto, Canada.

First Vice-President.—Dr. F. Schavoir, of Stamford, Conn.

Second Vice-President.—Dr. Caleb Brown, of Sac City, Iowa.

Secretary.—Dr. John Gerin, of Auburn, N.Y.

Treasurer.—Dr. R. J. Nunn, of Savannah, Ga.

Executive Council.—Dr. Robert Newman, of New York, N.Y.; Dr. W. J. Morton, of New York, N.Y.; Dr. W. J. Herdman, of Ann Arbor, Mich.; Dr. W. T. Bishop, of Harrisburg, Pa.; Dr. G. Betton Massey, of Philadelphia, Pa.

The customary votes of thanks were passed, after which the retiring president appointed Drs. Newman and Nunn a committee to conduct the newly elected president to the chair.

Dr. Dickson, on receiving the gavel, addressed the meeting in a particularly happy vein, and requested the hearty co-operation of each member to make the meeting in Buffalo an unqualified success. He would announce his appointments of the committees on the investigation of scientific questions without unnecessary delay; he declared the meeting adjourned, to re-convene at the call of the executive council.

THE NORTHERN SOCIETY OF ELECTRICAL ENGINEERS.

The annual dinner of the Northern Society of Electrical Engineers was held at the Grand Hotel, Manchester, on Thursday evening. Mr. J. S. Raworth, the president of the society, occupied the chair. About 70 gentlemen were present, including Messrs. H. Edmunds, John Ely, W. P. J. Fawcus, J. Nasmith, Harry Pollitt, Alderman J. J. Meakin, T. Browett, J. F. L. Aspinall, J. H. Holmes, C. H. Wordingham, H. Lindley, H. Alabaster, Percy Rosling, J. Hardie McLean, J. Slater Lewis, E. L. Madgen, E. M. Lacey, J. B. Atherton, J. Atherton, S. V. Clirehugh, and Geo. W. Lowcock (the hon. sec. of the society).

The Chairman said letters of apology for inability to attend had been received from the Lord Mayor of Manchester (Alderman R. Gibson), Alderman Hopkinson, Mr. J. Taylor, and other gentlemen.

"The Queen" having been toasted with musical honours,

Mr. Aspinall, locomotive engineer of the L. and Y. Railway Company, in proposing "The President and the Society," said their society, he understood, was going to do something to help the locomotive engineers. The locomotive engines still existed, but they were, of course, to be superseded, and trains were to be run more conveniently than by the locomotives of to-day. He did not know how it was to be done, but that no doubt would be pointed out. Personally, he wanted to see the day when the chemist and engineer would provide a storage battery from which they could get out of it

96 per cent. of the work they put into it, and do what they did with a gas-holder. It was delightful to see the electric cabs running about in London. He did not believe in the oil motor. As had been said, "It barked like a dog, and stunk like a cat." He hoped the electric gentlemen would produce something that would get rid of the difficulties to which he had just alluded.

The President, in reply, said success depended entirely upon themselves. It was a very remarkable fact that a long spell of bad trade often did more good to the trade affected than a spell of prosperity. Should it happen in the spell of prosperity which he saw looming (he would rather say beaming, for he did not like the word "looming") in the distance upon them that they were not able to take it up and fulfil the demand, then the very fact that they would not be able to meet it would offer a chance to their competitors on the other side of the German and Atlantic Oceans to come in and show English customers what they could do in the very midst of Manchester. He did not think the locomotive engines would be done away with; he was of opinion that the locomotive engineer would be able to apply electricity himself, and not leave it to the electrical engineer to do it for him. He thought that the driving of railway engines by electricity was within practical range. In the black country the Pumping Commission, which did the pumping for all the pits, had held a meeting in Birmingham, and the promotors had said they could supply electric energy at 1d. per unit. That made those who had steam engines contemplate disposing of them for the new energy. It rather frightened local authorities who now supplied such energy at 8d. and 9d. per unit. Therefore, there was likely to be opposition, but they in Lancashire must reduce the cost of the electric supply. In Manchester, under certain conditions, they could get it for 1½d. per unit. (A Voice: "At Bradford for a 1d.") They, in this city, were getting down to that. With a sufficient output, there was no reason why they should not supply electric energy at 1d. per unit. They must follow the example of America. The public must be supplied with what the electrical engineers knew they wanted before they asked for it, and then a market would be created for their manufactures. It was also proposed that they should add associates to their Society in the shape of the principal cotton spinners and machinery manufacturers of the country, in order that they might put to practical use the knowledge which the Society possessed.

The toast list also included "The Retiring President (Mr. C. M. Dorman) and "The Guests," responded to by Alderman Meakin and Mr. Nasmith.

During the dinner, and afterwards, a glee party, under the direction of Mr. J. H. Greenwood, entertained the company with songs, glees and sketches.

THE TELEGRAPH TROUBLES.

The Clerks' Point of View.

By CHAS. H. GARLAND.

(*Continued from page* 167.)

There are two claims made by telegraph clerks with respect to the maximum salary. The first is that they have a right, under existing circumstances, to rise to £190 as operators and without the intervention of arbitrary and practically insurmountable barriers. The second is that this maximum should be raised, as it is insufficient under the changed conditions of service and environment. The point to which they wish it raised is £230 per year in London, and £200 in the provinces. The first claim I dealt with in my last article; the second I will now discuss.

This claim for £230 as a maximum in London is no fanciful claim, fixed with no consideration for the circumstances which regulate wages, but is a fair estimate of the value of a telegraph clerk's work at the present day. Quite apart from the question of changing environment, the work itself has so far changed that a higher degree of skill is required, there is a far greater strain on the operators, imposed by the tremendously increased mass of work to be dealt with, there is a demand for greater general intelligence and higher educational qualifications, and technical training is almost a *sine quâ non*.

Let us hear what Mr. W. H. Preece, F.R.S., the Engineer-in-Chief, has to say on this increased demand upon telegraph clerks. "The progress of telegraphy has been phenomenal. That progress has been marked by a steadily-increasing demand for the exhibition of technical knowledge and skill on the part of the artisans and operators engaged in the engineering and commercial branches of telegraphy in this country, and we are able to bear witness to the fact that those concerned have responded to this demand in a way that does them infinite credit. A standard of technical knowledge that was exceptional in the telegraph service a few years ago, is now the rule, and the time is not distant when we shall look in vain and without regret for the engineering or commercial employé who has no knowledge of the principles of the science."

The same high authority has also summarised in a form which I will not attempt to improve upon, the actual requirements. "We require that all telegraphists," he says, "at some time of their career should possess an acquaintance with the principles and the laws of electricity as applied to telegraphy and telephony, and with the mechanical construction of the apparatus that they handle. They should also comprehend the nature of faults that occur in apparatus, and evince the ability to remove these faults, and generally to secure the maintenance of the apparatus. There is no doubt that this knowledge on the part of the staff very much increases the efficiency of the service. In days gone by an immense amount of time was lost in repairing faults, owing to the fact of the only persons who could repair faults being the engineering officers, who had to be sent for; whereas now, owing to the advance of technical knowledge, the clerks are able themselves to remove slight faults at once; the result is, that delays are removed, the service has better supervision, the work is simplified, and generally the condition of our apparatus and our lines is very much better than it used to be. I should like to say this, that whatever tends to promote rapid service means increased business to the Department. There is no doubt that the number of messages that are sent by telegraph depends almost essentially on the rapidity with which they are sent and delivered, and, therefore, technical knowledge being acquired by the staff, means an addition to the revenue of the Department, and therefore justifies the Department in incurring some expenditure in improving the staff and service." These lengthy quotations are justified by the important and unimpeachable testimony they bear to the difference of requirements now, and at the time when Mr. Fawcett fixed £190 as a fair remuneration for the work of a telegraph clerk. The increase in the mass and complexity of the work is borne out by the Postmaster-General in his 41st Report. "The growth of the whole business (of the telegraphs)," he says, "since 1870 (from less than seven to more than 71 millions) has been more than 10-fold. The number of offices has increased from 2,000 to nearly 10,000. The system, including submarine cables, now consists of about 35,000 miles of line, as compared with 15,000 in 1870, and about 215,000 miles of wire, as compared with 60,000, while the number of instruments has increased from 4,000 to over 26,000." This was written in 1895, and the increase during the intervening period has kept pace. With all this development, the work and strain of the individual clerks has also vastly increased. Speaking personally, I can say that each man works immensely harder, and more continuously now, than 15 years ago, and the difficulty of remaining clear-headed and steady amid all the rush and whirl of these millions of messages, the manifold complexities of circulation, the mysterious faults and imperfections of the new and delicate apparatus, increases to an enormous extent the wear, tear, and worry of a telegraph clerk's life.

The greater amount of work turned out cannot be attributed to the improved apparatus alone. As Prof. Marshall justly observes in his "Principles of Economics" (p. 316), "The more delicate the machine's power, the greater is the judgment and carefulness which is called for from those who see after it." And from the single needle and the Morse inker of 17 years ago, to the Wheatstone transmitter, with an attainable speed of 600 words per minute, and a working speed of 400 words per minute (*vide* Postmaster-General's 41st Report), or the Delany multiplex of to-day, what an increase in this demand for judgment and carefulness. The percentage of nervous complaints demonstrates the truth of this.

What increased reward does the Department offer for this increase in the quality and quantity of the work? Does not the "model employer" set an example in this matter? Far from it. By what appears to us to be a tampering with our rights, our prospects have been actually reduced. I showed in my last paper how the obtainable maximum as an operator had been reduced from £190 to £160. What wonder, then, that telegraph clerks are discontented? and what wonder if this gnawing discontent should unconsciously affect the output? I can assert truthfully that no formulated intention of restricting the output has ever gained any power among the staff, and the Postal Telegraph Clerks' Association has always discouraged such methods; but does not discontent unconsciously militate against the highest results? And under the conditions I have detailed discontent is inevitable.

It has been the custom of those opposed to us to speak glibly of the market value of our work and to assert that the present salaries—that is, the salaries with the reduced prospects of promotion—are sufficient, nay, liberal. The market rate of a man's work, as I understand it, is the point at which it is fixed by the influence of open competition, and except where powerful unions stand in the way, it is the lowest rate at which men can be induced to perform the work. In the case of a State monopoly, where there is no open competition to determine the rate, it is hard to say how this market rate is arrived at. The best method of determining a rate appears to me to be a consideration of the salary which will attract a class of men and women sufficiently well educated to come up to the best requirements of the department in the matter of efficiency, and also a salary sufficient in amount to retain the services of the most highly-skilled and efficient men in the Department. Sir Lyon Playfair, speaking before the Ridley Commission on the question of the fixing of the rates of pay for civil servants, takes practically this view. He says: "One thing that guided us very much in the terms which we offered was, that we took a great deal of evidence as to what the outside world gave for positions somewhat similar, and we found that civil servants were on these terms paid more liberally, and we could get the *élite* of the men outside who did similar work." This is undoubtedly as it should be. The rate should be such as to get and keep the *élite* of the profession in the service of the State. The *Daily News* of January 29th, 1895, said: "It is now acknowledged that to give high wages, and thus attract the pick of the market, coincides with sound policy as well as with the humane principles which ought to guide our civil administration." The Rt. Hon. James Bryce, M.P., speaking to a deputation of Aberdeen telegraph clerks on November 24th, 1897, said: "The State . . . . . ought to go upon the principle that it would not pay more than the market rate, but, that it would pay the best market rate." The present salaries and prospects held out to telegraph clerks are not consistent either with keeping the *élite* of the profession in the service of the State when opportunities of escape are offered, nor are they consistent with the principle of paying the best market rate. Nor, as the conditions of service become known, and the real nature of the prospects exposed, does the fierce competition for the places continue. Since last year's public notice of the telegraph clerks' position the number and quality of the candidates for the position has fallen immensely, as the Civil Service Commissioners' returns will show, and when the case is more fully understood there will be a still greater falling off. The *élite* of the class which would otherwise become telegraph clerks know they can put their educational abilities to a better and more profitable use.

The cable companies' scales are much higher than the Post Office scales for similar work, with the result that the best men are attracted from the postal service whenever the opportunity offers. To take only one instance: the Eastern Telegraph Company offers a scale of £50 by £12 to £204, as compared with the postal scale detailed in my last article, with its slow progress to the practically insurmountable barrier placed at £160. In Germany, where the cost and standard of living are very much lower than here, and where the service is slower and less efficient there is a maximum for the lowest class of operators of £162, and in Holland, where the same cheapness exists, a telegraph clerk can get £183 by the time he is 40 years of age.

So far are the conditions of service in cable companies and Colonial Governments superior to the postal conditions, that the advertisement of a vacancy invariably secures a rush of the very best operators. In a small office, like Newcastle, for example, 50 of its best men will apply for four positions under the Transvaal Government. Nearly the whole of the Preston staff will apply for one position in the Eastern Company, and such examples could be supplied *ad nauseam*. The result of this is, that the companies draw off many of the best men, and much of their success is to be attributed to the class of operators thus obtained.

How are the Post Office authorities meeting this increased demand on their men and the increased pay offered outside? By lowering the prospects and increasing the hardships of service; by reducing privileges and curtailing leisure. These things I believe to be not so much the fault of individual administrators as the fault of the system. An administrative system is the strongest of conservative structures, and when that system has been built up on unsound economic principles it requires more than the ordinary reforming spirit to break through it. And the principles underlying the present postal management are not those sympathetic and humane principles which should guide an administration which stands in the position of model to all other employers.

The demands of telegraph clerks are no straining after ideals. The scale which they ask is as follows:—The present scale as far as £50 per annum, and then by increments of £7 10s. to £140, thence by £10 to £230. This is for London. For the provinces the scale is lower, with a maximum of £200. It is an eminently reasonable demand. In a further paper I will defend the demand for changes in the lower portion of the scale. At present, suffice it to say that the clerks only ask that the £230 maximum should be granted under certain conditions. Upon reaching the Fawcett maximum of £190 they say: "We will be submitted to a test in theoretical and practical telegraphy and telephony, and will pass an examination in magnetism and electricity." By this means the department can assure themselves that the men who advance have kept pace with the conditions essential to the performance of the highest class of work in the most efficient manner. It is possible to stop men of bad conduct at any point in the scale, and the demand is, therefore, that men of unimpeachable character and high merit only should pass the £190 point, which Mr. Fawcett fixed for operators pure and simple. On the suggested scale a clerk would not obtain £190 until after 19 years' service, and the maximum, after having passed the tests explained above, after 23 years' service.

By adopting this scale, the Department would ensure that essential factor in efficiency—a contented body of workers; it would put itself in a position to retain the *élite* of the profession in its service; it would make its scales nearly equal to the best market rate paid for telegraph operators, and it would approximate more closely to its proper position in the first flight of employers. Surely, with the evidences one can adduce of the immense advantages to the community of an administrative policy, guided by such principles, and attaining such results, the day should not be far distant when the reasonable demands of this important body of public servants will be conceded.

(*To be continued.*)

SOME NOTES ON SINGLE-PHASE MOTORS.

By A. C. EBORALL.

(*Continued from page* 173.)

In regard to the winding, it should have as small a self-induction as possible, and is preferably of copper strip placed edgeways in the tunnels. A three-phase star-connected winding is often used, the common junction being made on the iron work of the rotor. Apart from the question of self-induction, it is generally inadvisable to use more than one conductor per slot, because, in order to comply with one of the conditions stated above, such windings are frequently very irregular. That this is so may be seen from an inspection of fig. 10, which is a six-pole rotor winding with one conductor per slot.

The simple short-circuited form of rotor described above is only used for small motors, its employment above 6 H.P. for low frequency, and 4 H.P. for high frequency motors not being attended with satisfactory results. Imagine a single-phaser with such a rotor being started up by means of any phase-splitting device. With the rotor just beginning to move, the slip is equal to the frequency of the supply current in the stator, and the whole arrangement is practically a short-circuited transformer. Large currents circulate in rotor and stator, and the torque would be enormous if it were not for leakage. The presence of the air-gap directly promotes leakage, which means that the rotor currents have a great lag in regard to the stator induction, and hence the motor will have very little torque, although drawing large

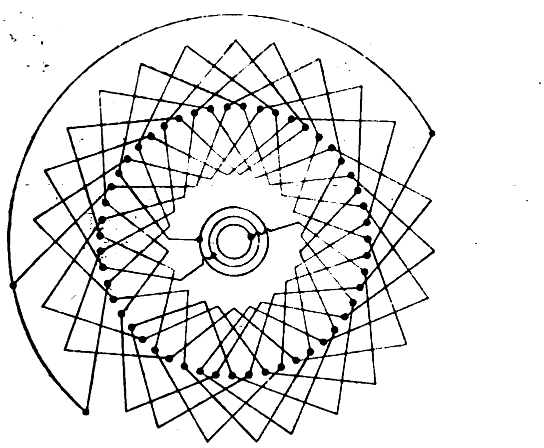

Fig. 10.

currents from the line. To sum up, then, the disadvantages connected with the employment of a simple squirrel cage rotor for motors of any size:—

1. A large wattless current is drawn from the mains, greatly disturbing the circuit on account of the voltage drop in the lines and generator, and also on account of the great demagnetising effect which it produces on the generator fields.

2. The large rotor current exerts a very powerful demagnetising effect on the stator, choking back the induction, and hence reducing the torque.

3. The rotor current being nearly wattless, it is out of phase with regard to the induction produced by the stator, and consequently the torque produced is insignificant.

4. Much of the impressed pressure may be lost in the stator coils to overcome resistance, and

5. The motor is liable to burn out.

Of course, as soon as the rotor begins to move, the rotor currents decrease, owing to the slip decreasing, and they will continue to decrease until the motor approaches its speed limit, determined by the stator poles and frequency of supply.

Thus for motors of any size, it becomes necessary to reduce these large wattless currents, both for the sake of the supply system, and to secure effective starting of the motor. The best way of decreasing the wattless current in amount, and also of bringing it more into phase, is to put a non-inductive resistance in series with the short-circuited part at starting, cutting it out as the rotor runs up to speed. This means that the short-circuited part must be wound with a regular winding, its ends being connected to slip-rings on the shaft, as mentioned above—or the ends may be connected to a resistance placed in the body of the rotor, which may be short-circuited by an external device when the rotor has got up speed.

The former plan of having the resistance exterior to the motor is on the whole preferable to the latter, as it allows the resistance to be varied, and gradually cut out, which does not disturb the circuit so much.

The resistance for this purpose must be as non-inductive as possible; if not, it may still further increase the lag. A three-phase winding is always employed on the rotor, this having the minimum of dead points, and the rotor resistance is generally star-connected, to correspond to it.

This insertion of a non-inductive resistance into the rotor is very effective. It cuts down the current in amount, and therefore limits the demagnetising effect, and at the same time this rotor current is brought more into phase (and hence the stator current also), and as a result a greatly increased torque is produced. The other harmful effects enumerated before are in consequence either greatly reduced, or obviated altogether.

Assuming the motor to be started with two currents o frequency, n, and differing 90° in phase, the *starting* torque is

$$\frac{2\, n\, \mathrm{K} \cos \phi}{\text{Rotor impedance}},$$

where ϕ is the lag in the rotor bars, and K a constant depending on the strength of the magnetic field, and on the winding of the rotor.

$$\text{As } \cos \phi = \frac{\mathrm{R}}{\sqrt{\mathrm{R}^2 + 4\, \pi^2\, n^2\, \mathrm{L}^2}} \qquad \text{(Fig. 6)}$$

the expression for the starting torque becomes

$$\frac{2\, \pi\, \mathrm{K}\, \mathrm{R}}{\mathrm{R}^2 + 4\, \pi^2\, n^2\, \mathrm{L}^2},$$

which is a maximum when $2\, \pi\, n\, \mathrm{L} = \mathrm{R}$.

Hence to get the best results, the value of the starting resistance plus the rotor resistance should be equal to $2\, \pi\, n\, \mathrm{L}$ ohms, and should be capable of being decreased as n decreases. Single-phasers are never started with two currents differing 90° in phase, and hence in practice it is usual to make the value of the starting resistance somewhat less than this.

The effect of resistance in the short-circuited part of a single-phase motor supplies the reason for several points of construction that might otherwise not appear. When describing the construction of rotors with simple short-circuited bar-winding, it was stated that the rings at the ends are made of considerably smaller section than the total section of the active bars. This is simply to enable the motor to start effectively, the resistance of the copper rings, with such large currents as they would carry at starting, being quite sufficient to enable this to be done.

There is, however, another factor entering into the case. At any given load on a motor, the torque is proportional to the product of the induction in the air-gap and the current in the rotor conductors; and therefore, the impressed stator pressure being constant, the rotor must run at such a speed that the slip allows enough pressure to be generated in the bars to overcome the resistance of its conductors. The slip is really somewhat greater than this, on account of leakage and pressure drop in the stator. It therefore follows that for a given torque the slip is nearly proportional to the resistance of the rotor, and hence that the effect of giving a certain amount of resistance to the rings, and of working with high current densities, is to cause a corresponding drop in speed of the motor, and must not be carried too far. To make a motor synchronous, all that has to be done is to put a lot of copper in the rotor conductors, and what is done in practice is to use very few bars, and work with a low current density. This construction of rotor implies a "notched" field, which further contributes to a synchronous tendency. Such motors must be run up to practically synchronism before they will go in, and take a large current, their no-load current also being high, perhaps 50—60 per cent. of the full-load current. They will carry but very little overload, their power factor also being small. Such motors are very rarely asked for—their only application would seem to be for driving rectifiers. The Pollak rectifiers running at Frankfort and Zürich are driven by motors of this type built by Messrs. Brown.

REVIEWS.

Formulaire Physico-Chimique. Par Donato Tommasi. Paris: Librairie Industrielle, 30, Rue du Dragon.

This book is a compilation of 475 pages containing a vast number of data, and much practical information, useful to physicists and chemists, and, in a less degree, to engineers and manufacturers. Chapter I. treats of fusion, solidification and vaporisation; Chapter II. of the solubility of gases, and of mineral and organic solids; Chapter III. is devoted to refrigerating mixtures; Chapter IV. to the expansion of solids, liquids and gases; Chapter V. to the phenomena of capillarity; Chapter VI. to the densities of solids, liquids and gases; Chapter VII. to thermo-chemistry and the law of thermal constants; and, lastly, in Chapter VIII, information will be found on the spheroidal condition of bodies, the dissociation of ammoniacal salts, the nascent condition of bodies, the electromotive force of the principle voltaic couples, the capacity of certain accumulators, and the composition of some varnishes, mastics and cements.

A table of great utility to the practical man in pyrometry, since it gives fixed points of temperature, at small distances apart, from 954° to 1,775° C, is that relating to the Prinsep alloys of silver with gold and platinum.

The data relative to the liquefaction of hydrogen, oxygen, nitrogen and atmospheric air are derived from the researches of Wroblewski and Olszewski. No mention is made of Prof. Dewar. The formula of Nordenskjold for the solubility of salts, in terms of their solubility at a given temperature, is quoted; but is not explained in such a way as to render it available to the non-mathematical worker. We notice that in the table giving the degree of cold produced by the mutual reaction of solids the minus sign is accidentally omitted in the case of the mixture of sodic carbonate and manganic nitrate, which is capable of lowering the temperature to − 26° C. The data given on p. 195 relative to the increased expansion of wires—excepting in the case of hard steel—when a given temperature is produced by the passage of a current, instead of by ordinary means of heating, may be useful to some of our readers. The same may be said of the table on p. 229 giving the weight, at 15° C., of one drop of various liquids, or the number of drops to 1 gramme, when 20 drops of distilled water weigh 1 gramme. The densities (or specific gravities) of alloys of lead and antimony are given on p. 240; and a knowledge of them may sometimes save the trouble of a chemical analysis.

The tables giving the percentage of real acid in solutions of hydrochloric, nitric, sulphuric, and chromic acids of given density, will be of value to the electro-chemist; but, even in this work, the mistake of omitting to state the temperatures to which the given densities are to be referred has in some cases been made. Nor, in regard to Anthon's table (p. 273) is it mentioned that the sulphuric acid, of which various proportions are to be added to 100 of water to obtain a dilute acid of a required density, must be of the very inconvenient specific gravity 1·86—inconvenient, because the density of oil of vitriol at 15° C. (59° F.) is 1·8455, whilst that of H_2SO_4 is 1·8426. Correct tables are given of the percentages of caustic potash, and soda, in solutions of various densities.

The chapter on "Thermo-chemistry" is unsatisfactory from the point of view of the electro-chemist, who may seek in vain for the heat of constitution of the compounds, such as $PbSO_4$ and PbO_2, in which he is most interested.

On p. 380 is given a table of the capacity in ampere-hours of 1 kilogramme of plates in various accumulators. For the Laurent-Cely elements this is given as 9 to 10 ampere-hours; for the Dujardin, 15 to 18; for the Julien, 15 to 20; and for the Tommasi, 25 to 30.

The work ends with a description of two kinds of electrolytic cartridge which, the author states, may be advantageously substituted for gunpowder or dynamite for blasting in oal mines.

Light: Visible and Invisible. A series of lectures delivered at the Royal Institution of Great Britain, at Christmas, 1896. By Silvanus P. Thompson, D.Sc., F.R.S., M.R.I. London: Macmillan & Co., Limited, 1897.

This publication, in book form, of Prof. S. P. Thompson's Royal Institution lectures on light is well worth reading. This most fascinating, as well as the most exact of physical sciences is treated by an enthusiastic and gifted lecturer; and though the conditions of a popular lecture do not admit of exact demonstrations, and an immense subject is skimmed over in a few pages, the reader is left keenly interested, and stimulated to seek more information elsewhere. No doubt the style suffers from its lecture-room origin, and the colloquial form is occasionally irritating; but, taken as a whole, it attains its object, and may well stand with Kempe's "How to Draw a Straight Line," Vernon Boys's "Soap Bubbles," and some other volumes which owe their origin to the same source, the theatre in Albermarle Street. Prof. Thompson's method of treating geometrical optics by considering changes in the curvature of a wave surface, is more philosophical than that by considering changes in the directions of rectilinear rays, and we accept his assurance that it is of practical advantage in teaching. Unfortunately, in teaching some sciences, notably mechanics, the most philosophical course cannot conveniently be followed. The chapter on rays emitted from vacuum tubes is particularly interesting, and gives a clear and concise account of the state of knowledge at the time the lectures were delivered; but the distinctions drawn by Prof. Thompson between many different kinds of cathode rays would not, we think, be generally accepted. As is often the case in books of this kind, the appendices, in which particular points of interest are discussed in detail, are the cream of the whole.

ON SOME RECENT INVESTIGATIONS IN CONNECTION WITH THE ELECTRO-DEPOSITION OF METALS.*

By J. C. GRAHAM.

So far as the author of this paper is aware, there has been no very satisfactory examination made into the conditions which are necessary for the rapid deposition of metals from their solutions by means of the electric current.

The experiments which are described in this paper appear to throw some light on the subject.

When an electric current is passed through a strong solution of sulphate of copper, the copper is deposited in a very perfect condition so long as the current density does not much exceed 200 to 300 amperes to the square metre. According to Donato Tommasi † the following are the figures:—

Poids déposé en grammes par heure et par $d\ m^2$.	Intensité du Courant en amp. par $d\ m^2$.	Nature du dépôt de Cuivre.
12	10·2	Très bon.
50	42·7	Sablonneux sur les bords.
124	106·	Mauvais sur tout le Contour.

And Tommasi adds, "Suivant H. Fontaine, pour bien opérer, il ne faut pas en pratique dépasser 1 ampère par décimètre carré de surface de Cathode, lorsque les anodes sont en cuivre chimiquement pur."

The deposit here spoken of appears to be the very good sort of deposit which is requisite for electrotyping and similar purposes, for it is beyond doubt that much denser currents can be used if the smoothness of the face of the deposit be not the principal object aimed at.

The author of this paper has made many inquiries of copper depositors for the purpose of ascertaining what is the maximum current density which is actually used by them in the practical deposition of copper, and has been unable to obtain any definite information. But so far as it is possible to form a judgment, the current density is not the same in all depositing trades, and very seldom exceeds about 300 amperes to the square metre of cathode surface.

The fact is, that the current density at which copper can be thrown down so as to obtain a good deposit depends very largely upon the thickness of the required deposit. A current density which would give a good deposit of $\frac{1}{1000}$th of an inch thick would give a very bad deposit $\frac{1}{50}$th of an inch thick, because every minute imperfection becomes enormously exaggerated as the process goes on. And this tendency to exaggerate original imperfections becomes much more marked as the current density is increased.

This effect, due to the time element, makes it very difficult to use exact language in speaking of the character of the deposit.

The effect of current density may be described in general terms as follows:—If the density be about 100 amperes to the square metre, the deposit is quite smooth and of a very pale salmon colour. If the density be increased, the surface, although still of a good colour, begins to get rough, and feels to the touch something like emery paper; if the density

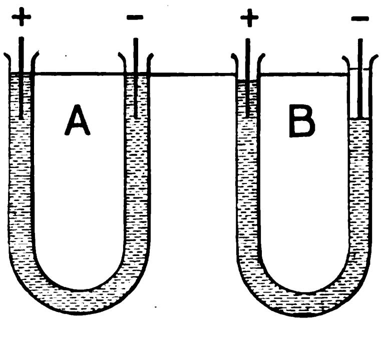
* Communicated to the Royal Society.

† "Traité Théorique et Pratique D'Electrochimie."

be further increased the deposit soon becomes discoloured, and if it be still further increased, hydrogen begins to appear in quantity on the cathode, and the copper is thrown down as a non-coherent chocolate-coloured mud.

The development of hydrogen may very well be accounted for, if it be assumed that the copper atoms in the electrolyte, which are immediately adjacent to the face of the cathode, are, in the case of dense currents, thrown down on the cathode more rapidly than they are replaced by the ordinary circulation of the electrolyte and by diffusion. If they are thrown down more rapidly than they are replaced, a time must soon come when the current has to force its way through the hydrogen molecules, which are adjacent to the cathode, and then hydrogen will be generated on the face of the cathode as well as copper.

It appeared to the author that it was not improbable that the generation of hydrogen was the most formidable obstacle in the path of rapid deposition, and that a rapid circulation



of the electrolyte over the surface of the cathode might possibly prevent the generation of hydrogen by maintaining a sufficient path for the current through copper molecules.

Some circulation is no doubt taking place in every bath where electro-deposition is in progress, and in some cases it is promoted by waving the cathodes to and fro, and probably also the atoms composing those molecules of the electrolyte which conduct the current change places and waltz round one another, according to the commonly accepted theorem, but the following experiment appears to point to the conclusion that this waltzing action is not accompanied by any movement of the waltzing atoms towards the electrodes.

A U tube was taken filled with an acidified solution of sulphate of copper, as shown in Diagram A, and a copper anode and a copper cathode were dipped into the electrolyte at the two open ends of the tube. This form of tube was adopted so as to prevent any circulation taking place. A very small current was then passed through the solution from the electrode marked + to the one marked −, and continued for two or three days. At the end of this period the electrolyte on the cathode side was in the condition shown in Diagram B. As far down as the cathode reached, all the copper in the solution had been taken out by deposition on the cathode, and immediately below the lowest point of the cathode the solution appeared to be unchanged. No change whatever had taken place round the anode so far as the eye could judge.

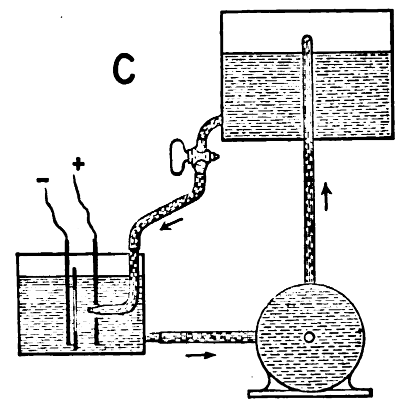
If the waltzing action had been accompanied by any movement of the atoms towards the electrodes, one would imagine that just as each atom of copper was thrown down on the cathode another atom of copper would have waltzed into its place, and consequently that no change in the electrolyte would have been expected in the neighbourhood of the cathode, but that a change might have been expected in the neighbourhood of the anode, especially if the anode had been made of some insoluble substance.

The experiment was, therefore, repeated with a lead anode substituted for a copper one. The same change was again noticed round the cathode, but no change was noticed round the anode, which could be observed by the eye.

The waltzing action does not, therefore, appear to have any appreciable effect in preventing the gradual exhaustion of the copper atoms on or near to the face of the cathode.

Mechanical circulation appeared, therefore, to be necessary to renew the copper atoms on the face of the cathode; and the next point which was investigated was whether the current density could be materially increased if, by means of a forced circulation, a continuous supply of copper atoms could be maintained on the face of the cathode.

To determine this, the apparatus shown in Diagram C was tried. In it the electrolyte was pumped up into a tank about



40 centimetres above the level of the electrolyte in the depositing bath. From this tank it was allowed to flow down a pipe, and out at a jet (below the surface) directed against the face of the cathode.

By these means a tolerably violent circulation of the electrolyte over the face of the cathode was obtained.

(To be continued.)

SOMETHING TO LEARN.

Englishmen do not, as a rule, know half as much of the United States as they ought to, advantageously to themselves; but we need not pride ourselves very greatly on our ignorance on this side. There is, or appears to be, quite as much amongst Americans with regard to conditions and facts in Great Britain; and we notice this more especially in connection with the prospects of electric traction on this side.

There is, no doubt, a great deal of business to be done, but some of the American technical papers give their readers very misleading information; and it seems a pity that garbled accounts should cause unnecessary trouble and expense. For instance, if a local authority in England considers the question of municipalising the tramways, a note on the subject probably appears in some of our trans-Atlantic contemporaries, implying that the said local authority is in the market for material. Forthwith circulars and price lists—perhaps even agents or representatives—appear on the scene, only to find out that two or three years must elapse before any orders can be given; and even then that home-made material will have the preference.

A recent example of this same "want of completeness," to put it mildly, occurs in the last issue of the *Street Railway Journal*, where a table is given purporting to comprise the principal cities of the British Isles and their tramway systems. Opposite to a number of these (perhaps 20) is printed the word "None"; and amongst those towns which are accordingly to be exploited for tramways are such as Hull, Salford, Bolton, Preston, Burnley, Huddersfield, Gateshead, Leith, Rochdale, St. Helens, West Bromwich, Bury, Wigan, Hanley, Devonport, Hastings, and Barrow-in-Furness. Out of all the lot, we believe that it can only be said of one that tramways do not yet exist, so we are somewhat puzzled to imagine where on earth the *Street Railway Journal* gets its information from.

It is, however, instructive to refer to some other figures supplied by our contemporary (with which we have no occasion to quarrel), to the effect that the British Isles possess about one mile of street tramway for every 40,000 inhabitants. In the nearest equivalent American area there is one mile of tramway for every 2,400 inhabitants, and the proportion of railroads is nearly the same, being one mile to every 1,800 inhabitants in Great Britain and one to 660 in the equivalent American area. We cannot, therefore, plead that many of the American street railways (*i.e.*, interurban and suburban lines), are represented with us by ordinary railroads.

Although the list of British towns without tramways drawn up by our contemporary is not to be relied upon as perfectly accurate, there is, nevertheless, nothing for us to boast about in the matter of tramway mileage.

THE NEW LYNN INCANDESCENT LAMP.

The *Electrical World* (New York) for January 29th, contains an article on an improved incandescent lamp which is being manufactured by the Lynn Incandescent Lamp Company, Mass. The mysterious commencement of the article leads one to expect improvements and novelty of a striking order. The company, has, in the course of its business of renewing burnt out lamps of different makes, taken note of all the weak points and defects of such lamps, and as a result of this special knowledge and observation, has turned its attention to producing a lamp which should embody all the good points of the best, without their defects. As might have been expected, the new lamp is pronounced to be unequalled "in the important qualities of uniformity, long life, and maintenance of candle-power."

Passing from the general to the particular, we come to a description of some of the special features and processes employed in the construction of this lamp—a description that is likely in places to provoke a smile on the faces of those acquainted with the details of lamp manufacture.

"In the construction of its new lamp, the company does not use cellulose filaments. It believes that the 'flashed surface' on the filament is the necessary factor, and therefore uses a material of higher specific resistance than cellulose, and one which admits of the greatest possible amount of 'flashed surface.' It has been the effort of the company to meet the demand from critical consumers for a uniform, efficient and high grade lamp, equal to its renewed lamp in life and sustained candle-power. One of the principal factors of the success of the Lynn Company in the manufacture of its lamps is its method of producing high vacua. On January 4th this year, Letters Patent were issued to Mr. E. F. Dwyer, the president and manager of the company, on a process of producing high vacua, which consists, substantially, of removing the main portion of the gases contained in the lamp bulb by pumping. A current is then passed through the filament and the exhaustion continued. A 16 C.P. lamp is run at about 32 candle-power, which brings the filament to an extreme white heat and excludes all the occluded gases contained in the filament. This is a new feature of lamp factory practice, the old idea being that the lamp would be strained if run above the normal candle-power; this would be true if the lamp were finished. The blackening of the bulb of the lamp is due to the condensation of the volatile carbon given off by the filament, and also from small particles of carbon thrown off mechanically, and by burning the filament to this extremely high temperature, all of these gases are thrown off and carried away by the pumps, the whole carbon becoming one homogeneous mass.

"But going back to the method of exhausting the lamps, the gases remaining in the lamp bulbs are mainly those which were purposely added during the process of exhaustion. As the lamp cools this remaining vapour condenses upon the cooler portions as a solid, leaving an almost absolute vacuum in the bulb. . . . . . . An important factor of the process is a mechanical pump which rapidly produces the necessary rough exhaustion. This pump in itself will, it is said, exhaust lamps equal to a mercury pump and can be used without the chemical process, but the latter saves much time and, as stated above, gives the almost perfect result."

From this not particularly lucid description of Mr. Dwyer's method of exhaustion, it is gathered that certain chemical bodies, which are capable of producing vapour at a high temperature, are introduced into the lamps whilst raised to high incandescence and during the running of a mechanical pump; and that by reason of the almost complete condensation of the chemicals on cooling, a peculiarly high vacuum is produced. This method of procedure is not new, however, having been patented in this country by Prof. Dewar in 1893—which patent, it may be remarked, anticipates in many important respects the now largely used Malignani process of chemical exhaustion. An article discussing this point was published in the Electrical Review last May. It may, of course, well be that Mr. Dwyer uses a different chemical, or chemicals, to those proposed or used by others, which gives him superior results. If so, no claim to this effect is made. It is to the principle of the process, so far as we can understand it, that attention is called.

NEW PATENTS.

[*Compiled expressly for this journal by* W. P. Thompson & Co., *Electrical Patent Agents,* 322, *High Holborn, London, W.C., to whom all inquiries should be addressed.*]

ELECTRICAL REVIEW.

VOL. XLII. | MARCH 4, 1898. | No. 1,058.

CONTENTS:

THE ELECTRICAL REVIEW.

Published every FRIDAY, Price 4d.

The Oldest Weekly Electrical Paper. Established 1872.

TO BE OBTAINED BY ORDER FROM ANY NEWSAGENT IN TOWN OR COUNTRY.

OFFICE:—4 LUDGATE HILL, LONDON.

Telegraphic Address: "AGEKKAY, LONDON." Code A B C.

Telephone No. 963 Holborn.

ALL Letters should be addressed to the Proprietors, H. Alabaster, Gatehouse & Co.

ADVERTISEMENT RATES ON APPLICATION.

The "Electrical Review" is the recognised medium of the Electrical Trades.

SUBSCRIPTION RATES.—In *Great Britain*, Post Free per Year, 19s. 6d. To *all other countries*, per Year, £1 4s.

BINDING.—Subscribers' numbers bound, including case, for 4s. each volume.

CASES.—Cloth Cases for Binding can be had, price 2s. 6d. each.

READING CASES, to hold from One to Twenty-six Numbers until the Volume is complete for Binding, can now be had from the Publishers, Price 6s. or Free by Post (in Great Britain), 6s. 6d.

FOREIGN AGENTS.—*New York:* D. VAN NOSTRAND, 23, Murray Street. *Paris:* VEUVE J. BOYVEAU, 22, Rue de la Banque. *Berlin:* ASHER & Co., 5, Unter den Linden.

Cheques and Postal Orders (on Chief Office, London) to be made payable to Mr. H. ALABASTER, 4 Ludgate Hill E.C.

A STRIKE LESSON.

THE latest issue of the *Amalgamated Engineers' Monthly Journal* contains an article dealing with co-operation, which our contemporary considers to be worth more than passing notice. So far as we ourselves can learn, co-operation has not been a huge success in its principal home—Lancashire. We are at least aware that there is a good deal of surprise expressed by people generally as to the very considerable amassment of property by many managers of "co-op." stores, whose salaries could never account for a tithe thereof.

The article in question recognises the need of capital in any industry. No industry can be carried on without capital, nor is capital of the slightest use unless present in sufficient quantity, and backed by a sufficiency of patience to await fructification. The A.S.E. ~~writer~~ speaks of capital being banded together to do battle for privilege and monopoly, to control even Government, and boycott the small employer into subjection. *Engineering* thinks the words privilege and monopoly have got a bit twisted. The fight was rather over the question of the Union's privilege of ordering how employers should conduct their works. Any monopoly claimed was claimed by the A.S.E. for its own members' exclusive right to certain work, while boycott may be left to the reader's imagination.

The article urges men to become their own employers, to devote their surplus capital to co-operation—it is something that any surplus is admitted. Unlike *Engineering*, however, we do not quarrel with the quality of free spending of the working man, though we may quarrel with some of the directions of his expenditure. If a man saves and invests his savings, he helps on industry and reaps the benefit both directly and indirectly. If the workman does not save he must be helping trade very directly, but the huge prosperity of the big brewers seems to negative the idea that, as a rule, the free spender is helping himself very much, as there is very little labour in brewing. Few towns so small as Burton turn out so large a nominal value of product. *Engineering* recommends saving in beer and "baccy," in order to secure at once capital to start a works big enough to employ a fair proportion of the men in a given factory who should elect to go on the saving plan. Efficiently managed, and with profits ploughed in, men might soon all become their own employers. But jealousy and mistrust are great enemies to co-operation. Efficient management would demand a better wage than the ordinary workman, and the manager's post in a co-operative factory, owned by the men who would have to obey the, perhaps, servant manager, would not be a happy one. John Burns's saying that no man was worth over £500 a year was, says our contemporary, a very foolish saying.

We, ourselves, remember a case in Manchester where a man was discharged because his employers could not admit the propriety of "any servant of ours earning £3,000 a year." They discharged him, and the business simply died out. The *A.S.E. Journal* cites an instance of a co-operative engineering works at Leicester which is a success, but there is somewhat of a suspicion, however, that it is nursed.

There is also a South London Engineering Society engaged chiefly on bicycles, but it requires both shareholders and customers. We venture to say that if working men want to save and own works, there is no better way at the present time than that open by way of the Limited Liability Act. A limited company with a good board and an able manager, and articles of association forbidding any shareholder worker interfering, save in the meetings, might do some good. Railway shareholders are all part of a co-operative concern, and many railway servants, perhaps, own more shares than their superior officers; but this avails them nothing if they neglect their duties.

There are, however, various ways in which a working man may save without risk, and provide for a rainy day. He may keep up his trade union as a benefit society, and also have a share in the so-called war chest. The war chest ought to be used, however, for peace in place of being an incentive to fight, as the late fund of £350,000 so unfortunately proved to be.

Undoubtedly capital is apt to be greedy, and never more so than when it can use labour of either hand or brain to the best advantage, and to secure big returns. It should be the aim of both the hand and the brain worker to do the best possible for himself and for capital, while at the same time being able to refuse to be squeezed. The wilful waste of the A.S.E. fund was made when capital was not trying to squeeze labour, hence the folly of the strike. Why was not the £350,000 put into a modern factory to make, say, direct acting steam pumps on an eight hours' day, with none but members of the A.S.E. to do every piece of work, with none but A.Es. on machine work—with no half pay boys or youths, and with all the modern tools run at the same slow speeds allowed to employers? It is a bit foolish this call for co-operation from men who profess it proper to disallow a man to work more than one tool. We fear the writer in the *A.S.E. Journal* has little economic knowledge.

It is not a little strange to see how the working man can be persuaded out of large strike levies for months at a time. Say there are 80,000 members of the A.S.E. Then 4s. a week from each is £16,000, or nearly a million annually. Strike levies recently were as high as 6s. weekly. Every week a nice little business could be taken over. But this they will not do.

Is the Nervous System a Coherer?

In a note presented to the *Academie des Sciences* on December 27th last, M. Branly pointed out some striking analogies between the conductivity of discontinuous conductors, and the conductivity of the nerves for nervous currents. That physiologists have already recognised a general analogy between a nerve and an electric conductor, is proved by their use of the term "nervous current." Up till recently, however, they appear to have looked upon the nerve as a continuous conductor. But, in recent years, histological researches have shown that the nervous system is composed of discontinuous elements—*neurones*—without any cementing substance between them, and connected together by the contiguity of their ramified extremities only. It follows, that the nervous wave propagates itself by contiguity, and that it is arrested by any defect in the contiguity. If it is no longer possible to maintain that there is any analogy between the nerves and continuous conductors, it will be evident that a very striking analogy exists between the nervous system and a system of discontinuous conductors. Several results, deduced from a comparison of the working of discontinuous conductors, and the physiological action of the nerves, appear to point to some analogy between them. In the same way that a shock reduces or annihilates the conductivity of discontinuous conductors, *traumatism* produces anesthesia and hysterical paralysis, due to a suppression of nervous transmission either in the sensory or motor nerves arising from imperfect contiguity of the nerve terminals. On the other hand, electric discharges act most efficaciously as a cure for hysterical paralysis and anesthesia, just as electric oscillations augment the conductivity of discontinuous conductors. This points to the hypothesis that the effect is determined in both cases by the contiguity, or something equivalent to the contiguity, of the elements. The parallelism between the effects of shock and of sparks upon coherers and upon the hysterical nervous system may be recognised in the susceptibility to reaction under a feeble action which remains after a powerful initial shock. This M. Branly has shown to be true of coherers in his note to the Academy of December 6th, and it is well known to be a property of the nervous system. High frequency discharges, and the electrical oscillations which accompany them, are well adapted to render discontinuous conductors continuous; and these discharges have been shown by MM. d'Arsonval and Apostoli to exercise a decided therapeutic effect upon the affections due to defects in nutrition. If these affections are of a nervous order, and are capable of being attributed to an imperfect transmission of the nervous current, it is permissible to assume that electric oscillations act so as to re-establish between the nerve elements a contiguity which was becoming insufficient. Branly has shown, on a former occasion, that continuous currents of sufficient E.M.F. produce by their transmission through coherers the same effects as electric discharges at a distance. This action of continuous currents is subject to the same general laws as the action of electric discharges; persistence, disappearance with shock and heat, sensibility to less E.M.F. produced by the previous action of a battery of high E.M.F. Continuous currents also act upon the nervous system, and it will be an interesting subject for research to determine whether their action is analogous to that on coherers. M. Branly does not maintain that coherer and nervous actions are the same in every respect, but he considers that the similarity is sufficient to form a valuable guide to the electrotherapeutist in his future researches.

High Speeds on Electric Tramways.

To those accustomed only to the feeble crawl of horse tramways—pounding along at the enormous velocity of three to four miles an hour—it seems impossible that there should ever arise any danger of serious collisions between tramcars on dark nights, or in foggy weather, when running on a single track. The usual plan is for one to wait at a fixed turn-out until the other one comes, and sometimes the "wait" is considerable. With the introduction of electric traction, however, the entire service becomes speeded up, and the motor-men grow rather inclined to "steal a turn-out," especially if by any chance they should be late already. With frequent traffic and a more or less indefinite time table, it is, of course, advisable, if not necessary, to put in double track; but narrow streets may forbid this, and consequently the fact must not be forgotten that much greater care will need to be exercised with fast-running electric cars against the danger of collisions on the line than is now the case with horse traction. Several of these accidents have already taken place in the United States, though from the particulars published it would appear that sheer recklessness on the part of one or other (perhaps both) of the motor-men has been the cause of what should be termed "incidents" rather than "accidents." With a more serious loss of life than has hitherto been the case, they will become "catastrophes," and by that time tramway managers will make proper rules for their *employes* and see that they are carried out.

AN ELECTRICAL HYPOTHESIS FOR THE SOLAR AND PLANETARY SYSTEMS, AND SOME OF THEIR ASSOCIATED PHENOMENA.

By DELTA.

COINCIDENCE OF SUN SPOTS WITH MAGNETIC VARIATIONS

Reference is made in the first article to the coincidence of sun spots with magnetic variation; fig. 8 shows the coincidence in graphic form.

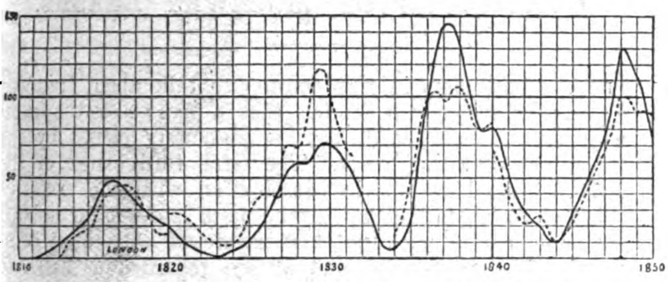

FIG. 8.—SUN SPOTS AND MAGNETIC VARIATIONS (From Langley's "New Astronomy").

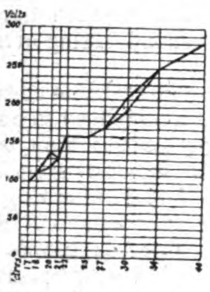
In the diagram, for which we are indebted to Mr. Langley, the amplitude of the oscillation of the magnetic needle is shown by the dotted line, the full one being constructed from the relative number of spots.

FURTHER EVIDENCE OF THE INCREASE OF ELECTRICAL POTENTIAL WITH INCREASED DISTANCE FROM THE EARTH'S SURFACE.

Diagram, fig. 9, shows graphically the result of experiments made by Exner* with small balloons, with collectors in in open and free air.



Distance from the earth.

FIG. 9.

The same experimentalist obtained much higher result from observations made on the side of a mountain, *vid* diagram, fig. 10.

METHODS AND APPARATUS FOR EXAMINING THE ELECTRICAL CONDITIONS OF THE EARTH'S ATMOSPHERE.

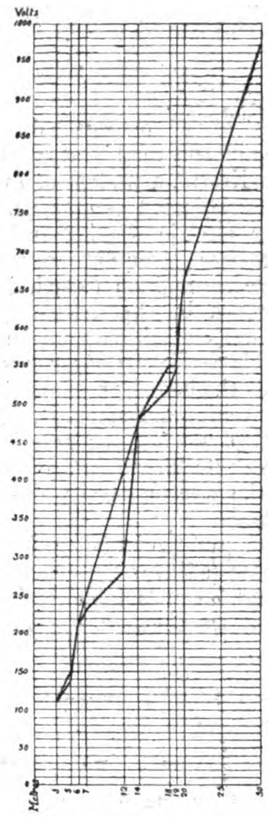
There should be little difficulty in devising means for the determination of the variations of electrical potential in mountainous districts, so that the barometric and electrical and thermal gradients can be recorded from day to day.

In France most excellent use has already been made of the Eiffel tower for the determination of the vertical barometric gradient. Here in England, unfortunately, we have no structure of equivalent altitude that can be readily employed for observative purposes, and we must, therefore, regret that the Wembley tower has not yet been completed.

In the absence of structures of high altitudes an alternative method has quite recently been employed, and with the best results as far as it was applied to the determination of barometric and thermal gradients.

This apparatus is shown by illustration fig. 11, and for which we have to thank *La Nature*. It will be seen to consist of a closed basket suspended from a kite of suitable carrying capacity and containing instruments of great precision and sensitiveness, and made of aluminium, for recording temperature and registration in mid air.

The apparatus registers variations of pressure of a fraction



Distance from the earth.

FIG. 10.

of a milim., and variations of temperature down to one-third of a degree centigrade. A check on the exact altitude can be trigonometrically determined by taking from two stations separated by a proper basis, two or more sights and their corresponding vertical angles, it is easy to determine the difference that exists between the height of the kite deduced from the barometric variation and the altitude determined mathematically.

The kite apparatus could be supplied with a multiple quadrant electrometer, with an automatic equipment for continuously recording the changes in the electrical condition of the atmosphere.

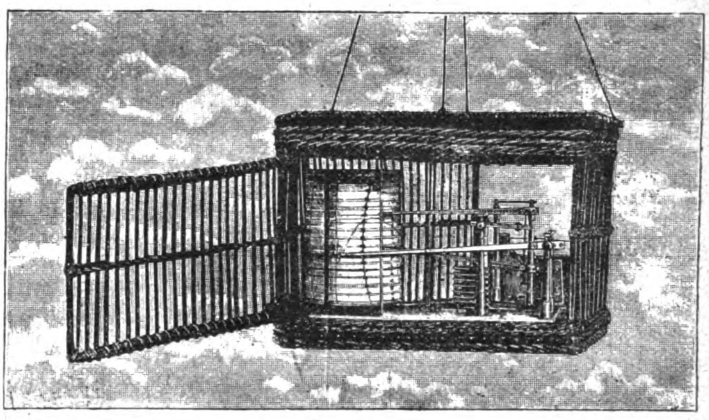


FIG. 11.—ALUMINIUM REGISTERING APPARATUS FOR STUDYING THE VERTICAL GRADIENT.

A suitable electrometer would record the myriad upon myriads of electrical lightning flashes, whose intensity is too slight to become luminously visible to the human eye.

It has also been suggested that Hertzian resonators, properly tuned, could be devised of sufficient sensitiveness to indicate all lightning discharges.

* Ursache und Gesetze der Atmos. Elec.

PROPOSED CONFERENCE OF EXPERTS.

The proper equipment of a perfectly equipped meteorological station that could satisfy the requirements—that the still almost unknown electrical condition of the atmosphere calls loudly for—is a subject that deserves the consideration of a joint conference of experts in the electrical, meteorological, astronomical, physical, and medical sciences.

THE DETERMINATION OF THE ELECTRICAL POTENTIAL NECESSARY TO PRODUCE LIGHTNING FLASHES.

The importance of a concentrated attention into the electrical condition of the earth's atmosphere could not be overstated. Even Kelvin, a student of over half a century, is still compelled to rely upon assumption in building up a calculation of the electric density and force of a given enclosure, representing a given displacement of air.

He says, on the assumption (which he is compelled to admit may be proved by experiment to be untrue), that electric density is uniform throughout the spherical shaped enclosure, each cubic centimetre of air experiences an electrostatic force towards the boundary in simple proportion to the distance from the centre and amounting at the boundary to nearly 10 per cent. of the force of gravity upon it.

Kelvin suggests the following form of calculation to obtain some measure of the electric density and force of a specific atmospheric enclosure.

Where V equals the potential indicated by the water dropper, a equals the radius of the spherical hollow (displaced by the water drop), ρ equals the electrical density of air at the distance r, from the centre of the spherical hollow; then we have

$$V = 4\pi \int_0^a \left(\frac{r^2}{r} - \frac{r^2}{a}\right) d\,r,$$

if ρ is constant

$$V = 2/3\, \pi \rho a^2$$

$$\rho = 3\, V/2\, \pi a^2.$$

Suppose $V = 38$ volts*

$\therefore \quad a = 50$ cm. and $\rho = 2{\cdot}4 \times 10^{-5}$.

The electrostatic force at a distance r being

$$4/3\, \pi \rho r = 10^{-4}\, r.$$

If we assume that a spherical conductor charged electrically—with a value of electricity equal to that possessed by a cubic centimetre of air—and placed at a point midway between the centre of the sphere and its surface, then $\frac{50}{2} = 25$ is equal to half the radius a.

Then between the surface and the centre of the enclosure, representing a given air displacement, there will be experienced a force equal to $2{\cdot}4 \times 10^{-9} \times 25$, equivalent, approximately, to $6{\cdot}10^{-8}$ grammes, or 4·8 per cent. of the force of gravity on a cubic centimetre of air of a density of 1/800.

Kelvin† applies this calculable hypothesis to the estimation of the electrical potential of a cloud constituted of air and watery spherules.

He says: "If a uniformly electrified globe produces a difference of potential of 38 volts between its surface and its centre, a globe of a kilometre diameter electrified to the same density reckoned according to the total electricity in any small volume (electricity of air and of spherules of water), would produce a difference of potential between its surface and its centre of 38,000,000 volts."

Kelvin, on this hypothesis, estimates that in a thunderstorm flashes of lightning show us differences of potential equal to millions of volts, but not as he says, perhaps of many times 38,000,000 volts, between places in the atmosphere distant from one another by half a kilometre, equal to 0·31 of a mile.

According to Trowbridge, to drive a spark across a gap between two terminals 4 feet apart requires a voltage potential of no less than 1,200,000, therefore a discharge of lightning one mile long will require the enormous pressure potential of over 100,000,000 volts; therefore 0·31 of a mile would require 31,000,000 volts, which is not far from Kelvin's calculated results. The voltage figure taken in the calculation is, however, rather too low, as is proved by Exner's determinations, see diagrams 9 and 10.

* See diagram, fig. 7, ELECTRICAL REVIEW, page 140.

† See Kelvin's paper, *Proceedings* British Association Meeting, 1894.

THE MOVEMENT OF FREELY SUSPENDED CONDUCTORS OF HIGH AND LOW POTENTIAL IN THE ATMOSPHERE.

McAdie makes the ingenious suggestion based on the well known fact that as the aluminium needle of the ordinary Thomson electrometer always moves from the region of high + to the region of low − potential, therefore a charged body, freely suspended in the atmosphere, will move from the place of high to the place of low potential. This may explain the movement of charged electrical conductors such as clouds, and thus produce the coloured aggregation effect, a common phenomenon of cloudland.

CONDITIONS OF TRAMWAY LEASES.

IT seems customary in this country to talk about tramway *leases*, even although it is a fact that in many cases the tramways are not leased at all, but are absolutely owned by the companies operating them. The fatal 43rd clause of the 1870 Act has however—in combination with the excessive spirit of socialism that has sprung up of late—so far imbued the popular mind with the brief nature of a tramway company's life, that they one and all are regarded as liable to early extinction; they are not, as the Americans say, "franchises"—involving almost absolute freedom for a long, if not an indefinite time—but are merely short "leases" or tenancies which will be terminated as soon as possible in favour of the local authorities concerned.

The latter have had their appetites in this direction considerably whetted by the development of electric lighting, and if only to help make their electricity works pay better, they will seize every opportunity of taking over the tramways and working them, or at least supplying current for them.

There are, however, very many existing interurban and other lines (whose number will without doubt largely increase) where the local authorities are practically obliged to grant fresh leases; and there are also the new lines projected as tramways or light railways which have similarly to be dealt with in regard to eventual taking-over by the local authorities.

It is much to be regretted that in such instances our local authorities are too little inclined to learn from the experience of others, but simply trust to their own crude and ignorant ideas of what is the most advisable course from their own very narrow point of view, squeezing all they possibly can out of the tramway interests and giving nothing in return. Such short sighted methods cannot be too strongly condemned: we do not advocate perpetual rights for tramways such as are common in the United States, but for a local authority to have the option of taking over a private tramway enterprise at break-up value, after a life of 20 or even 30 years, is as ridiculous as it is unfair and impolitic.

Such a condition simply means that the tramway is starved by its management, no public benefits are or can be offered, and no good is done to anyone, simply because the local authority is afraid of even a limited monopoly, and the tramway company regards the public body as a band of duly accredited robbers who steal not for private gain but for the public good.

If inquiries were made of other countries before imposing conditions of lease or franchise in regard to tramway lines, it would, we believe, result in valuable information being brought forward of a nature, if acted upon, to give satisfaction on all sides. For instance, the average "life" of a tramway on the Continent will probably be found to extend over 40 or 50 years at least, though, of course, the conditions of road maintenance, money payments, &c., vary in each case, and therefore also vary the value of the concessions apart from their actual length.

Some very interesting and useful particulars in regard to this question are contained in a pamphlet that has just reached us from the municipal engineer of Shanghai, Mr. Charles Mayne. This gentleman appears to have circulated a list of questions amongst the principal local authorities of the United States and Canada, as to the period of years for which tramway concessions have been granted; the amounts payable to the local authorities by the tramway companies for the right of user in regard to the public streets, and the works of paving, road maintenance, &c., to be carried out by the tramway companies.

Out of a total of 34 towns and cities ranging in population from 20,000 to 700,000, no less than 23 have granted perpetual rights to the tramway interests. One other system is almost as well off with a life of 999 years, another exists for 99, two for 30, two for 25, and four for 20 years; most of the short terms being granted by Canadian towns, so that we may credit the "public authority ownership" idea with being essentially British. Twenty-two out of the entire number pay the local authority in each case absolutely nothing for the privilege of using the streets, and 20 out of these 22 have a perpetual franchise. The other two are limited to 20 and 25 years respectively.

The majority are called upon to pave and maintain the roads, &c., between the rails and for 12 or 18 inches outside; but these conditions vary a great deal in each case, and no valid comparison can be made, but enough is given to show that English tramways suffer at present from disabilities of a much more serious nature than those inflicted by local authorities in any other country where tramways have developed at all.

PRACTICAL WORK WITH THE BALLISTIC GALVANOMETER.

By LAWFORD H. FRY.

The reflecting ballistic galvanometer has an unpleasant reputation for absorbing a great deal of time and temper in the making of measurements with it. A certain amount of this reputation is deserved, for the charting of the various ballistic constants, involving, as this does, a series of determinations of the coefficients of damping for different resistances in the galvanometer circuit, and their insertion in the somewhat unpleasant formula,

$$C_B = c\ \frac{T_0}{\pi}\ k^{\left(\frac{1}{\pi}\tan^{-1}\frac{\pi}{L}\right)},$$

is necessarily a lengthy proceeding. But this need only be done once, and by the adoption of the methods given below, work with the ballistic galvanometer will lose much of its slowness. In the formula above, the symbols have the following meanings:—

C_B is the so-called ballistic constant, which varies with the resistance in the galvanometer circuit, and which comes from the formula, $Q = C_B \cdot \alpha$, where Q is the quantity of electricity flowing through the galvanometer, and α is the corresponding deflection.

c is the ordinary constant of the galvanometer.

T_0 is the time of swing of the galvanometer in an open circuit.

k is the coefficient of damping of the galvanometer, and may be defined thus: if $b_1, b_2, b_3, \ldots b_n, b_{n+1}$, be the amplitudes of successive swings of the galvanometer,

$$k = \frac{b_1}{b_2} = \frac{b_2}{b_3} = \ldots = \frac{b_n}{b_{n+1}},$$

$$\text{hence } k^n = \frac{b_1}{b_2} \times \frac{b_2}{b_3} \times \ldots \times \frac{b_n}{b_{n+1}} = \frac{b_1}{b_{n+1}},$$

$$\text{therefore } \log. k = \frac{\log. b_1 - \log. b_{n+1}}{n},$$

L is the natural logarithm of k.

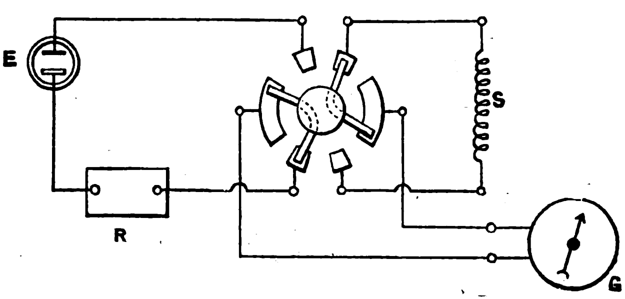
From this we see that, so long as the magnetic part of the instrument remains unaltered, the only factor in the formula that can change and alter the ballistic constant is the ordinary constant of the galvanometer, which will be altered by the shifting of the telescope and scale, which is a thing very likely to occur. Then to work in the most economical way, things must be so arranged that for the recalibration of the instrument the only measurement to be made is the determination of the ordinary constant. To accomplish this, a chart of the changes in the factor,

$$k^{\left(\frac{1}{\pi}\tan^{-1}\frac{\pi}{L}\right)}$$

of the ballistic constant must be made and preserved; this factor changes with a change of resistance in the galvanometer circuit, but is unchanged by shifting the telescope. The form of this chart will be a curve having as its abscissæ the resistances in the galvanometer circuit in ohms, and for its ordinates the values of the expression,

$$k^{\left(\frac{1}{\pi}\tan^{-1}\frac{\pi}{L}\right)}$$

Then to recalibrate the galvanometer all that will be necessary will be to determine the ordinary constant for the then position of the telescope, and to multiply it by the value of the other factor obtained from the curve by measuring the length of the ordinate to the curve, which passes through the point on the axis corresponding to the resistance of the galvanometer circuit with which the measurement is to be made. If, however, such a chart is not in existence and the ballistic galvanometer is to be used for some measurement, as for instance, the determination of the coefficient of mutual induction of two conductors, the following method will



enable the instrument to be calibrated and the measurement to be made with as small an expenditure of time as may be. The idea of the method is to determine the ballistic constant for the one galvanometer circuit resistance with which the final measurement is to be made. For such a determination the following quantities have to be measured. The ordinary constant of the galvanometer, c, the time of swing of the galvanometer in an open circuit, T_0, and the coefficient of damping of the galvanometer for the circuit with which the final measurement is to be made, k. These first measurements will be best made in the order in which they have been enumerated. In all work with the ballistic galvanometer it will be practically necessary to have two workers. In the present case we shall consider two men working as quickly as may be, so that one man changes the connections while the other is making observations; usually, however, speed will not be such an object but that it will be well to work out the results of each step before changing the connections to those for the next step, thus giving an opportunity for checking the work if the first result does not appear right.

To proceed with the measurements:

For the determination of the ordinary constant there will be needed a Clark element, or other standard cell, a resistance box containing resistances up to at least 30,000 ohms, and a two-way switch. These must be connected up, as shown in fig. 1, the switch allowing the galvanometer to be connected up in series with the element and resistance box, or to be short-circuited through the wire, S. This last is to bring the galvanometer to rest quickly between measurements, or if set swinging accidentally. The measurement of the constant is made in the usual manner.

If e be the E.M.F. of the cell,

r be the resistance in the box,

g " " of the galvanometer,

C " current in the "

α " deflection of the " due to the current C,

and c " constant " "

$$e = C\,(r + g)$$

but $$C = c \cdot a$$
$$\therefore e = c\,a\,(r + g)$$
$$\therefore c = \frac{e}{a\,(r + g)}$$

now, e, r, and g are known, hence observing a gives c. With the ballistic galvonometer a steady deflection, a, can, of course, not be obtained; but the swing being noted the distance of the mid point of the swing from the zero of the scale gives a. This measurement having been made, the galvanometer must be set swinging sufficiently vigorously to enable the time of swing to be determined. This may be done by opening and closing the battery circuit periodically, the period being chosen to correspond to the swing of the instrument. Having set the galvanometer in motion, the switch must be turned open so that the swing continues undamped. Then to measure the time of swing. Measure the time taken for, say, 10 swings, divide the time by the number of swings, thus finding approximately the time of swing. Then let the galvanometer swing for a longer time, making, perhaps, 100 swings, note whether the number of swings is odd or even, divide the time by the approximate time of one swing as determined above, this will give the number of swings made during the whole time; the division will not give a whole number, but, of course, a whole number of swings has been made, here make use of the knowledge as to whether the number of swings was odd or even, if it was odd take the odd number nearest the quotient obtained by the division as the number of swings made, if, however, the number was even take the nearest even number, then divide the whole time of swing by the number of swings thus obtained. The quotient will be the accurate time of one swing. While one observer is watching the swing of the galvanometer, the other can be removing the element and resistance box and substituting for them the circuit in which the final measurement is to be made. To find the coefficient of damping of the galvanometer. Set it swinging, this may be done by sending the same current through which is finally to be measured, if this does not give a sufficiently wide swing several impulses may be given to help each other. The galvanometer being set swinging, turn the switch so that the galvanometer is damped by the circuit in which the final measurement is to be made. Note the amplitude of a number of successive swings, the number of swings will depend on the damping of the galvanometer, if the resistance is small so that the coefficient of damping is large, only a few swings will be wide enough to be read with accuracy, if, on the other hand, the damping is low, through a large resistance, more swings can be taken. Eleven swings will be found to be a convenient number to take, only the amplitude of the first and the last need be noted, for these are all that occur in the formula

$$\log k = \frac{\log b_1 - \log b_{n+1}}{n}$$

With 11 swings, n will be 10, a convenient number to divide by.

To avoid unnecessary work in the determination of the factor it will be well to obtain the value of

$$k^{\frac{1}{\pi} \tan^{-1} \frac{\pi}{L}}$$

by interpellation, from the accompanying table, which is taken from Kohlrausch, Leitfaden der Praktischen Physik.

The advantage of using the circuit in which the final measurement is to be made, in the determination of the damping coefficient, is that then only the one measurement of this coefficient is necessary, and no measurement need be made of the resistance of this circuit; thus a possible source of error is avoided, and a considerable amount of time and trouble is saved. The operations described above give all that is needful for the calibration of the galvanometer.

The use of a standardised induction coil will reduce the trouble and calculation in the determination of the ballistic constant to a very small quantity.

For if M be the coefficient of mutual induction between the spools of the coil,

C the current in the primary spool.

e_m the E.M.F. induced in the secondary spool by the disappearance of the current C.

c_m the current in the secondary spool.

t the time of change of current.

Q the quantity of electricity flowing through the secondary spool, and

R the resistance of the galvanometer circuit,

then $$e_m = M \frac{d\,c}{d\,t}$$

and $$e_m = R \cdot c_m$$

$$\therefore M \frac{d\,c}{d\,t} = R \cdot c_m$$

$$\therefore M \cdot d\,c = R \cdot c_m \cdot d\,t.$$

$\therefore$ By integration $$M \cdot c = R \int c_m \cdot d\,t$$

but $$Q = \int c_m\,d\,t$$

$$\therefore M \cdot c = R \cdot Q$$

again $$Q = c_B \cdot a,$$

$$\therefore M\,c = R \cdot c_B \cdot a$$

$$\therefore c_B = \frac{M \cdot c}{R \cdot a}.$$

Hence, if M and R are known, all that is needful for the determination of the ballistic constant is the measurement of C and

the observation of a. That is by the use of a standardised induction coil, the determination of the ballistic constant may be effected by a simple current measurement and mere multiplication and division.

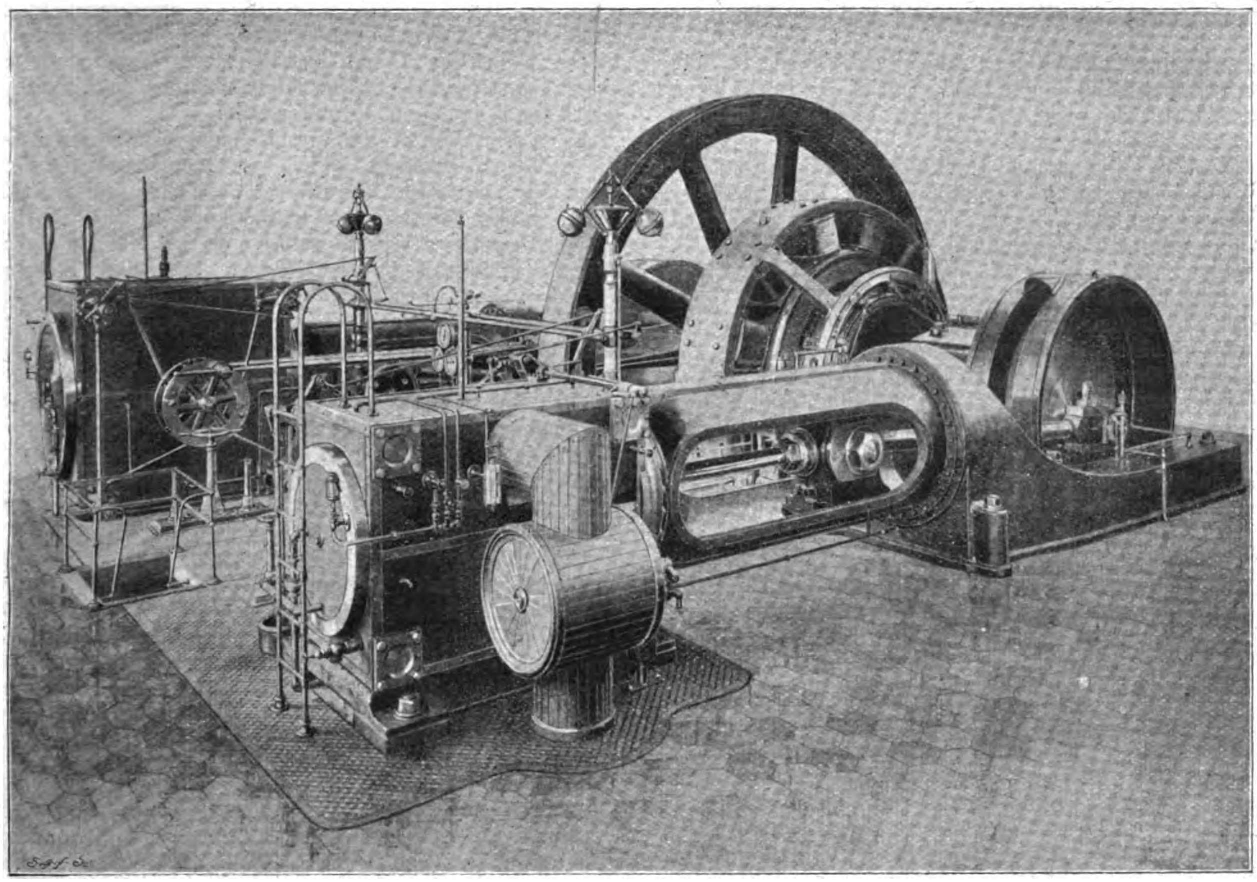
In the final measurement for which the galvanometer has been calibrated as above, it will be advisable to leave in the two-way switch, with a short circuit between two of the terminals, as this affords a very handy means of bringing the galvanometer quickly to rest between the measurements.

THE CENTRAL LONDON RAILWAY.

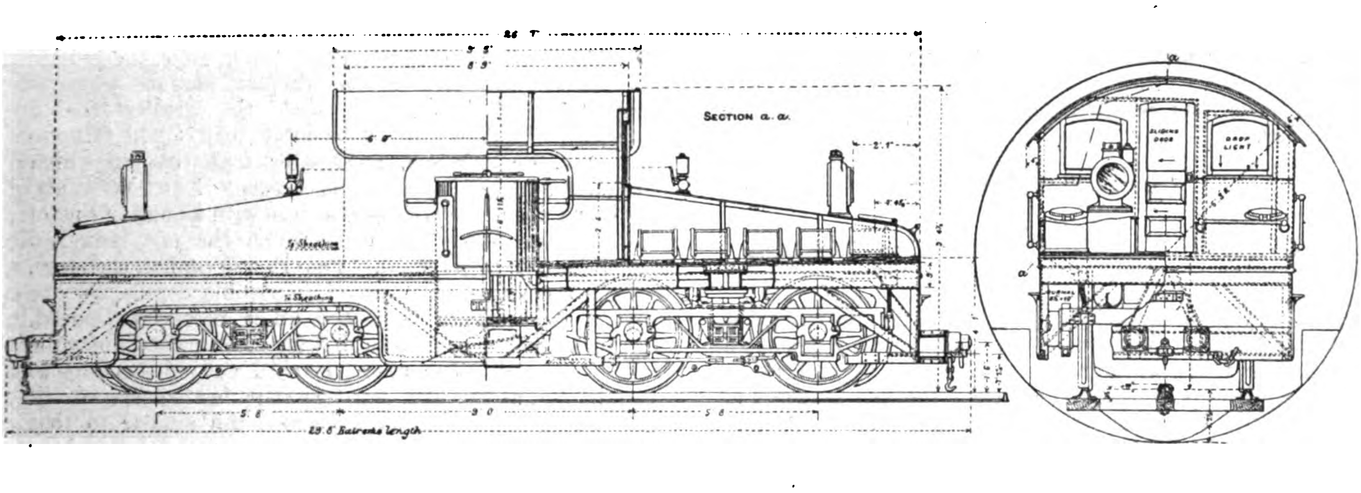
GREAT progress has been made with this gigantic undertaking, and last week of the total length of 22,880 yards of tunnelling, only 6,000 yards remained to be driven. Few people realise the enormous difficulties that have arisen in driving the tunnels. The work has necessitated not only the diversion of the sewers in many places, but round about the Bank the whole of the gas and water pipes had to be taken up and placed in different positions. Up to the present the energies of the railway company have been mainly directed to completing as far as possible that portion of the line that lay outside the City boundaries, and this to some extent, though not all, accounts for the somewhat backward state of the Bank subways. The foundations of the company's generating station at Shepherd's Bush have been begun, and no doubt this section of the undertaking will be completed about the same time as the other. It is perhaps hardly necessary to remind our readers that all the station lifts, some 49 in number, will be worked by electricity. On other electric lines in London the engineers have favoured the hydraulic system, and it will be interesting to compare the performance of the two methods.

We are able to give a few interesting details of the plant which is to be used on the line. The total length of continuous railway over which electric traction is to be provided, is about 6½ miles, exclusive of crossovers at stations and sidings.

It is intended to run a 2½ minutes' service, with trains of seven carriages each, with a total seating capacity each of 336 passengers, and weighing 105 tons loaded, exclusive of the locomotive. The average speed of the trains is to be 14 miles per hour, including stoppages at stations.



The electric plant, which is to be installed by the British Thomson-Houston Company, is on the three-phase system, and has been designed by their consulting engineer, Mr. H. F. Parshall. There are to be three sub-stations in the



lower portion of the lift shafts at the Davies Street, Notting Hill Gate and Post Office stations. Additional plant is to be installed at the Marble Arch station, but will at present be only of the nature of a spare plant.

The boiler plant will consist of 16 Babcock & Wilcox boilers, in eight batteries of two each. The evaporating power of each boiler is to be 12,000 lbs. per hour; the heating surface 3,580 square feet, and the pressure 150 lbs. per square inch. The boilers will be fitted with Vicars mechanical stokers, which will be supplied with coal by a conveyor from a storage tank on the top of the boiler house, having a capacity of 1,500 tons. The coal conveyor also serves to remove the ashes, and will be driven by electric motors.

Each engine is supplied with an independent combined jet condenser and air pump of sufficient capacity to take the maximum quantity of steam. The condensing and injection motor will be forced to the top of four Barnard cooling towers, each tower being furnished with two fans driven by electric motors. The engines are six Reynolds-Corliss cross compound condensing engines running at 94 revolutions per minute, to give 1,300 I.H.P. each, with cylinders 24 inches and 46 inches diameter × 48 inches stroke. The engines are capable of being run non-condensing, and either high or low pressure side can be run independently. Steel fly-wheel is to weigh 100,000 lbs., and is built up in eight segments. The engines are guaranteed for a consumption of 13¼ lbs. of steam at 1,000 I.H.P. when run condensing with 26½ inches vacuum. We are able, by the courtesy of Mr. Blackwell, who represents the makers, the

Edward P. Allis Company, in this country, to give an illustration of the exact type of engine which is to be employed.

The three-phase generators will have 32 poles, and a capacity of 850 kw., 500 volts, and 25 cycles. They are of the revolving field type. The coils of the stationary armatures are held in slots, there being ventilating ducts through the body of the armature, similar to the standard armature construction of the British Thomson-Houston Company. The total weight of each generator is 80,000 lbs. It is assumed that four of the six units will be sufficient to take care of the average load, and this will, therefore, provide a margin of 50 per cent. over the present requirements of the plant.

The switchboards have been specially designed, the high tension switches being double break, half of the break being on each side of the panel. The high tension contacts in every case are mounted on ebonite.

The Notting Hill Gate and Davies Street sub-stations will contain one rotary converter in each station, with necessary transformers and switchboards. At the Marble Arch and Post Office sub-stations, there will be two rotaries in each. Each rotary has a capacity of 900 kw., and will be of the 12-pole type, running at 250 revolutions per minute. They are capable of being run up either from three-phase, or the direct current side. As these are rotary converters in the exact sense of the word, that is to say, an alternating current of 330 volts pressure, passes into the machine, and is converted into a continuous current of about 500 volts on the other side, it is necessary to provide step-down transformers which reduce the line potential from 5,000 volts to 330 volts. These are of the air-blast type, but instead of following the usual plan of forcing the air through the transformers, the air is drawn through, and the hot air is expelled through sheet-steel pipes, running up the centre of the spiral staircase of the stations, thus providing ample ventilation for the sub-stations, as well as effectively cooling the transformers. The weight of each transformer will be 8,000 lbs.

The cables connecting the power-house with the substations, will be carried through the tunnels on brackets. They are of the British Insulated Wire Company's standard paper insulation type. The third rail will be of steel, weighing 80 lbs., to the yard of channel section supported on creosoted wood insulators, each joint being bonded with four flexible crown bonds. The rails of both up and down lines will be divided into four sections, and interconnected by circuit breakers.

The locomotives, of which drawings are shown on the previous page, will be mounted on two trucks, each truck carrying two motors of 150 H.P. The total weight of the locomotive is about 42 tons, the total length of locomotive being 29 feet, and the total height, 9 feet 8 inches.

There will be four gearless motors on each locomotive, one on each axle, and these will be controlled by series parallel controllers, provided with magnetic blow-out, which will place the four motors in series, two in series, and two in parallel, or all four in parallel, as desired.

The trains will be fitted throughout with Westinghouse air brakes.

THE EMPIRE AND TELEGRAPH CABLES.

In the varying accounts of a new and important scheme of telegraph cables, which have lately been widely circulated among the press, throughout the Colonies as well as in England, there is to be found sufficient internal evidence to warrant us in concluding that all of these emanate from a single source. Although differing somewhat in the manner in which the statements are presented, as well as in the style of treatment, still, in the main body of these paragraphs and articles, the recurrence of the same prejudiced and garbled statements all point to a common source of origin. We have frequently dealt in detail with the numerous points raised, but, as the subject has assumed a more interesting aspect lately, owing to the aggregation of errors which are now being so widely disseminated, it is, perhaps, well that the more important of these should again be treated of at the present time.

The subject of a system of submarine cables, which, starting from England, would be carried on to Cape Town, touching only at the various British possessions on the way, is not a new one, nor is the proposed continuation of such a line from Natal to Australia, *viâ* Mauritius, Rodriquez Island, and the Keelings, a new conception. A somewhat similar scheme was fully dealt with by Mr. Hofmeyr, when representing the Cape of Good Hope at the Imperial and Colonial Conference, held in London in 1887; and was recommended by him as an addition to the scheme for a cable across the Pacific Ocean from Canada to Australasia, which was one of the principal subjects before the Conference. This additional scheme, which, as a supplement to the Pacific cable, it may be remembered, was rendered necessary by the inefficiency of, and frequent interruptions to, the then existing system of cables, has lately assumed an importance which ten years ago it did not possess.

About the time of the first Colonial Conference it was the cables to Australia which were continually breaking down, but latterly the cables to the Cape have deprived them of the record for frequency of interruption, and, therefore, the supplementary scheme referred to by Mr. Hofmeyr is strongly advocated by the Eastern Extension Telegraph Company, the Eastern Telegraph Company, and its off-shoot, the Eastern and South African Telegraph Company; the latter of which suffers both in purse and reputation owing to the frequency of interruptions to the Cape cables.

The point to which we take most serious objection, is that the popular advocates of Mr. Hofmeyr's project hope to advantage their cause by a continuance of the system of inaccuracy in figures and statements advanced, and by so doing to prejudice opinion against the Pacific cable route. For example, it used to be roundly asserted that the depth through which a Pacific cable would have to pass was "estimated at 12,000 fathoms (or 14 miles) in some places." This assertion was contained in a note from the Postmaster-General of South Australia to his Government, and coming from such a source aroused a natural objection on their part to examine any further into the matter; more especially when the same authority further asserts, in the same note, with a courageous confidence worthy of a better cause, that "as the Government are aware, I have given this subject very great and careful consideration, more so, perhaps, than anyone else." We are glad to see that this figure (an utterly imaginary one) is now reduced, by others better informed, to "a depth of 5 miles"; it is not, however, made clear by these recent critics, that this latter depth (which really does exist) occurs in an isolated depression which is more than 600 miles away from the proposed Pacific cable route. We may mention here that there are two cables lying in West Indian waters which were laid within 60 miles from a similar depression, more than 4½ miles in depth, and one of them has been working for over 25 years without giving any exceptional trouble. An unbiassed examination of the Admiralty charts will prove to anyone, that along the proposed route of the Pacific cable, the general depth to be expected in the deepest sections averages about 2,700 fathoms, and that the greatest depth would in all probability not be more than 3,200 fathoms —a depth, we may say, no greater than that in which a cable has recently been laid between New York and Hayti, and about the same as that met with along the line of the Government-supported cable which has just been laid from Bermuda to Jamaica. The Pacific cannot, therefore, be looked upon as an ocean of impossible depths, nor one where a cable cannot be picked up if necessary; indeed, experience teaches us that a cable has been picked up at the depth mentioned. The route sketched out *viâ* the Cape to Australia has, as yet, been but very imperfectly surveyed it seems, however, to have an average depth similar to that through the Pacific Ocean, and in one place at least, along the Cape line, there is a depth of nearly 3,200 fathoms. Thus it will be seen that, as regards depth of water, the supplementary route has absolutely no advantage over the Pacific line.

It is true that a cable between Vancouver and Fanning Island would be longer than any one length suggested for the supplementary route, but the length required would exceed by less than 250 miles that of a cable at present being laid across the Atlantic; and would in reality be about 250 miles less in length than the advocates of the Cape route make it out to be. The following quotation from an Australian paper is another sample of the class of information circulated. Referring to the Vancouver-Fanning Island section, we are told: "This section is practically twice the length of the longest section of the 'Cape' proposal." Now, this is an utterly misleading statement, as the real length of the section spoken of is here increased, for the purpose of condemning it, by some 1,200 miles. As the writer in this case illustrates his article by a map on which the proposed lengths of "the Cape route" are all carefully set down, it seems incredible that he should be so ignorant, as he would appear to be, regarding the original scheme, which he criticises adversely. It has also been said that being a "single line" the Pacific cable has no alternative in case of interruption, but those who, in their anxiety to furnish objections, advance this as an argument, seem to forget that, if correct, the same objection also applies to the proposed single line from the Cape; and that should either of these single lines break down the already existing cables to Australia would afford more or less useful alternatives to one, as much as to the other, of these proposed single lines.

(*To be continued.*)

THE INSTITUTION OF ELECTRICAL ENGINEERS.

At the meeting of the Institution of Electrical Engineers, held on Thursday last, February 24th, Mr. G. Binswanger Byng read a paper on "The Manufacture of Lamps and Other Apparatus for 200-Volt Circuits." The author must have given to this paper a good deal of trouble and thought, and it is apparently written with a view mainly to arrive at some standardisation useful to manufacturers. Those who note the points in the different sections and discuss the views held by the author, are certain to help the object which he has had in view, and will benefit not only the members of the Institution but all electrical manufacturers.

We hardly agree, however, with Mr. Binswanger Byng that station engineers are neither unanimous nor possess co-relation of ideas as to the kind of fittings and accessories suitable for 200-volt circuits. On such matters as the desirability of ventilating fuse boxes, there may be divergencies of opinion; but the principle and more important details of design and construction are recognised and agreed upon, while experience has shown the wiring contractor—who, after all, is the most difficult person to move in the matter—that certain types of fittings will satisfy his client, the insurance office, and the supply company, as well as suit his pocket. Perhaps the most difficult thing to get to-day is a good long-break switch for currents above 5 or 6 amperes at 230 volts continuous, which combines the desiderata upon which a consensus of opinion exists. We trust, therefore, that switch and fuse design will receive more attention in the discussion than the mere question of high voltage *v.* low voltage.

The discussion was opened by Mr. Crompton, who, however, preferred to reserve his remarks until a later meeting, as these were to be confined to the arc lamp question, and he was not quite ready to speak. Mr. Boot, of Tunbridge Wells, took the opportunity of impressing the importance of minor matters, too often ignored, upon those present; one of these to which he attached importance as concerning manufacturers was the necessity of adopting standards in design, and keeping to them. One point he considered noteworthy is the undoubted economy effected in cost of cable required on a 200-volt as compared with a 100-volt job; and he had known of several cases where firms had made a mistake, and tendered for work under the impression that supply would be given at 100 volts, whereas, on this being corrected, and the pressure having been ascertained to be 200 volts, a revised offer at a reduced price had been made; the saving in cable more than compensating for the extra cost of fittings and lamps. While a standard length of fuse should be agreed upon for manufacturers to work to with different currents, where fuses are used on alternating circuits there is less necessity for great length than on direct current circuits.

This fact, although well known, does not seem to be so generally recognised as it might be. From the author's paper Mr. Boot thought one is rather led to infer that high voltage lamps are decidedly bad; that is, that it is impossible to make lamps as satisfactory all round as with lower voltages. He admitted the life of the former was not so long as the latter, also that the candle-power sometimes falls off rapidly, but the author had certainly made out a very good case for engineers using the Robertson lamps.

He considered that engineers would find that a good case had been made out for the adoption of the higher voltage. At Tunbridge Wells the supply had been changed entirely over, and the higher voltage generally adopted. It was a general practice to connect two 100-volt lamps in series, as many fittings allowed of this, and in a number of cases customers had two-light fittings, both lights being controlled by one switch. Cheap lamps were the rule nowadays, if those of 100 volts were wanted, as those discarded by 100-volt supply were to be obtained at a low price.

Mr. Mordey felt much obliged to the author for the mention of his name in the paper in connection with a type of fuse he had designed some years ago. He was afraid he had not had much experience with 200-volt lamps, but watched with very much interest the progress of their manufacture and use. He considered the author had done a great service in bringing up this subject at the present time, and regarded what was read as an excellent practical paper. In a few remarks on the specific resistance of carbon, he stated that this ought to be considered in relation to its specific gravity, differences in specific resistance have to do with the mechanical state of the material. An unflashed filament under the microscope showed itself to be a long string of cinder, and the particles were connected together in the fashion of what was, in the early days, called microphonic contacts. Flashed filaments become very much more a solid. On the first occasion he spoke at the Institution, in 1882 or 1883, experiments were cited, showing that carbon differed from metals in its behaviour, depending upon its mechanical state: finely-divided carbon behaves the same as finely-divided metal. It would be interesting to know if the pendulous filaments of carbon found in the gas retort of a gas-works, have been ever used for lamp manufacture, or if any attempts have been made to employ them.

Then advocates of high voltage supply must not forget that the question is practically being tried by jury, and speakers should give actual costs of different voltage lamps on circuit. Engineers must not imagine that the jury has been asleep; he had heard entirely unsatisfactory remarks from users of high voltage lamps, other advantages may balance the disadvantages; but the satisfaction of the public is the question. Central stations might take on their shoulders the whole burden, and thereby obtain control of the energy sent out for a given candle-power.

Mr. Mordey then referred to Mr. Robertson's paper in the Electrical Review, where the difference of effect of alternating and direct currents on the life of lamps was discussed. In Vienna, where the conditions enable reliable comparative tests to be made, it was found that there was a very decided gain where lamps were used on alternating circuits. There might be a commercial advantage in the supply of lamps to customers at a certain contract price.

With respect to arc lamps, his experience was that the getting out of the light from the arc was the important point, and with high volts the light gets out; but small current lamps at high voltage were very poor things, although even from a small crater the light can get out if the length of arc be considerable.

Mr. Binswanger Byng mentioned in his paper a novel "cut-out" for extinguishing the arc in an arc lamp automatically when required, but Mr. Mordey held that the cut-out in the old Brush lamp complies with all the conditions laid down.

Mr. Robertson stated that he had nothing to add to the information he had given the author when assisting him in the preparation of the section of his paper on incandescent lamps. Mr. Raworth thanked the author for his very excellent paper, and remarked that Mr. Boot and his friends would not be quite so happy if they had to make the lamps they use, or live with them. At the present time Mr. Raworth had to live with them, and had the opportunity of creating an enormously fine cemetery from the selections that lamp makers were good enough to send him free for trial. Some engineers state that they look for one in every dozen going wrong at the commencement of life, but he had 25 per cent. in a dozen, and in another dozen only two were left. Certain of the peculiar qualities of high voltage lamps—such as not burning horizontally with satisfaction—were rather important things to consumers and contractors, where the angle at which fittings were set might have to be altered to obtain decent results. Another point is that these high voltage lamps do take more current per candle-power than the lower voltages, a rather important matter to the consumer who resents an increased bill for lighting.

Mr. Shoolbred believed that the 100 and 110-volt lamp in the early days of electric lighting was quite as much an experiment as the 200 or 220-volt lamp is at the present time, and felt sanguine that the latter will prove equally successful, owing to the very large number of indirect advantages attending its use. There are many things to be considered besides the lamps, such as motive power, &c., and 400—500 volts can be utilised in many applications of electrical industry besides lighting. The author referred to the difficulties he had met with; many of these were due to not having had the advantage of discussing the question of standard pressure at an earlier date, when an attempt might have been made to avoid the existing discrepancies. The opportunity was lost then, but it would have been very much better to have arrived at something like unanimity in the matter while possible. We may emerge from seeming chaos to the best in the end.

The results attained so far are by no means discouraging. The restriction to a small size of bulb need not always apply, and there seems to be no insuperable difficulty in using a larger sized cap, particularly in starting in new localities. A reversion to olden time again is the expedient of using two lamps in series. Many years ago two 50-volt lamps were so connected, to enable the best lamps then extant to be connected on a 100-volt supply.

In horizontal positions lamps of high voltage are weak, but anchored and zigzag filaments can be used, while Mr. Shoolbred had certainly not experienced much trouble with such lamps in a horizontal position.

At this stage the discussion was adjourned until the first meeting in the current month, which will be held on the 10th inst., and we may expect a lively and useful discussion. It might not be out of place to again point out that the title of Mr. Binswanger Byng's paper is practically precise, and his intention obvious; a much better purpose would be served by dealing with the paper than by roaming all over the subject of supply pressures, and repeating what has already been said at the Institution when Mr. Addenbrooke's paper was read, at the Municipal Electrical Association on Messrs. Barnard and Couzen's papers, and at the Northern Society of Electrical Engineers, when Mr. Gibbings described his procedure and experiences at Bradford with the increased pressure. It is really time that it was made clear to wiring contractors and consumers what precautions are essential, and in what particulars wiring must be altered from the old fashion when 200 volts pressure is to be used.

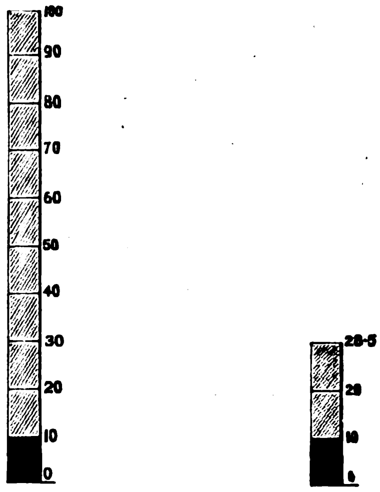
CORRESPONDENCE.

"The Burning Question."

Your recent articles on the above subject hardly do justice to the filter press as an aid in the burning of sludge. I notice calculations based on the assumption that the press removes one-third of the weight; and you have also expressed doubts whether sludge containing 65 per cent. of moisture can be considered pressed at all.

Now, 65 per cent. is not an excessive proportion of moisture in pressed sludge, and to reduce the percentage to this from the 90 per cent. in the original wet sludge requires the removal of about *two-thirds* of the bulk. The appended diagram (an old-fashioned affair now) will make this clear at a glance. The dark portion shows the solids, and the light portion the water. In the first case (unpressed) there are 90 parts of liquid to 10 of solids; in the second 18·5 parts of water to 10 of solids. That is to say, more than seven-ninths of the water have disappeared. If the solids are to be burnt, the press is plainly a valuable adjunct in the process—excepting always the case of Ealing.

Ordinarily, pressed sludge is not very combustible. You may drop a lighted match on a heap of it without any risk of a conflagration. Spontaneous heating does sometimes occur, running up the temperature to somewhere between



Unpressed Sludge with 90 per cent. of Water. The Same Pressed with 65 per cent. of Water.

110 and 120° F., and keeping it wonderfully steady at that for a considerable time. After heating and cooling there is a farther diminution in bulk; the cake formation is destroyed, and the heap becomes a mass of mere greasy muck.

Wet sludge has never been known to heat anywhere, and in most cases is about as combustible as Embankment mud on a wet day. At Ealing all this is different; the addition of a few cabbage leaves, meat-tins, and ashes confers remarkable burning qualities on the wet slop. It burns freely, and, after driving off its own moisture, has heat to spare, which is diligently utilised. No one has ever clearly explained the furious affinity for oxygen which characterises the Ealing sludge; some talk vaguely of dietic peculiarities of the contributory population, others of transmutation and the philosopher's stone. One had the theory that the solids consisted exclusively of potassium, but half an hour to leeward of the chimney stack dispelled that notion. The facts stand: ten parts of solids (and these mainly mineral and incombustible anywhere else) not only burn, not only evaporate nine times their weight of the water in which they were drowned; but they do these and yet have energy to spare for evaporating other waters, transformed later into mechanical and again into electrical energy, with effects visible to all men on the tops of arc lamp poles in Ealing Town. The old scientists used to dream about the circulation of matter, beginning, say, at the villager with a deal of guano in his destiny, who lay in the churchyard and made the grass grow. The churchyard fed the village sheep, the sheep the villager, and so the cycle went on. But what a poor figure these dreams make beside the realised results at Ealing. The natives live on the fat of the land; the dejecta, garbage, and refuse, elsewhere a costly nuisance, transformed into brilliant light; and all by mere cunning engineering and chemistry at the sewage works. Imagine this system applied to London—but we cannot.

J. Hetherington.

A Legal Point.

I should be pleased if you could kindly tell me whether the following action on the part of a corporation is legal or not, as it opens up a wide field:—

A corporation, with an electricity supply for the borough, has just secured an order for a large private installation outside their area of supply, and, in fact, in the area of an urban district council which has just got a provisional order. This corporation, I should mention, has its own wiring department, and the private installation is to consist of engine, dynamo, wiring, &c. My opinion is that this is illegal, as it is using ratepayers' money in a speculative business, quite outside the area of the borough.

Another point I should like to mention, and that is, the assistant engineer for this same corporation is at the present time acting as consulting engineer for two large private installations, thereby depriving consulting engineers, who are dependent upon it, of obtaining clients.

If the first instance is illegal, it will result, I understand, in the corporation being prosecuted, and a few words from you on the matter would, I feel sure, awaken interest in the subject, which, I think you will admit, is a serious one.

Legal.

[Although there may be some uncertainty as to the exact legal position of a corporation when undertaking wiring inside its own area of supply, there seems to be little doubt that a corporation is exceeding its functions when it undertakes wiring outside its own district. We do not think that much complaint can be urged against assistant engineers who do occasional consulting work, for it is doubtful whether their outside practice interferes very much with that of engineers who devote their whole time to consulting work.—Eds. Elec. Rev.]

Currents Necessary to Fuse Wires.

On looking over a table of above, taken from a paper by W. H. Preece, F.R.S. (*Proceedings Royal Society*, Vol. XLIV., March 15th, 1888), I noticed the following relations between the currents; and as they appear to have been overlooked hitherto, I thought they might interest your readers.

The following is part of the table in question:—

Wire-diameter in inches.	Cu. × 1	Fe. × 3	Sn. × 6	Pt. × 2	Pb. × 8	Al. × ¾
0·080	231·8	71·22	37·15	117·0	31·20	171·6
0·064	165·8	50·96	26·58	83·73	22·32	122·8
0·048	107·7	33·10	17·27	54·37	14·50	79·75
0·036	69·97	21·50	11·22	35·33	9·41	51·18
0·028	48·00	14·75	7·69	24·23	6·46	35·53
0·022	33·13	10·27	5·35	16·88	4·49	24·75
0·018	24·74	7·60	3·96	12·49	3·33	18·32
0·014	18·44	5·66	2·95	9·31	2·48	13·66
0·012	14·15	4·34	2·26	7·14	1·90	10·47
0·010	11·50	3·53	1·84	5·80	1·55	8·51

You will notice that, approximately, the current required to fuse Pt. is one-half of that necessary to fuse Cu.; also, that necessary to fuse Sn. is one-sixth of that required to fuse Cu.; and similarly for the other elements, using as divisor, in each case respectively, the figure given under symbol in table. So that, in order to get the approximate fusing current for any one of those elements, all one requires to know is the fusing current for one of the particular wires and the multipliers.

There is also the somewhat curious fact that if the currents necessary to fuse a given wire of Fe., Sn., and Pt., respectively, are added together, their sum is, approximately, the fusing current for Cu. wire.

This, of course, follows as a mathematical deduction from the above.

I may mention that the currents in above table are in amperes, and that the wires are of such lengths that end effects may be neglected.

W. H. F. Murdoch.

Glasgow, *February 28th*, 1898.

Information Wanted.

I would be very much obliged if any person could inform me, that when designing a ring slotted armature if the section is calculated as if the slots were solid, or how is it calculated, or what allowance is made for slots?

Also, supposing the slots were a quarter of an inch wide, would the air space between armature and fields be one-eighth of an inch on each side, or what proportion of width of slot would the air space on each side be?

Subscriber.

Cost of Long-Running Plant.

I should be much obliged if you or your readers would let me know of any electrical plant running more or less continuously at or near full load. I am anxious to find out the cost of generation under these conditions, and should be glad to be put into communication with the owners of any such plant, whether used for electro-chemical or any other purpose. The plant need not be of large capacity necessarily, but the main feature should be that it runs for long hours at or near full load. I imagine there must be cases where such plant is run more or less continuously all the year round, and if so, I should be glad to know of its existence. The main difficulty seems to be that the owners of such plant object, on business grounds, to making their experience public; but I hope it may be possible to find some cases where such considerations do not hold.

Atlas.

The Salaries of Assistant Electrical Engineers.

I do not think that I am the only one of your readers who will heartily endorse the opinions of the two correspondents in your last week's issue with respect to the magnificent salaries now being offered for responsible positions in station work. I could a little understand the policy of the borough electrical engineers, if they were ever in the habit of considering the ratepayers by keeping down their own salaries, as well as those of their assistants. But I notice that, whether the place be paying or not, the salaries of the chiefs are going ever upward, while those of their staffs are going down. I do not think that these men, in doing this, are rightly keeping up the dignity of their profession. For do not they themselves belong to the same rank of the profession as they, and do not they expect their assistants to have gone through the same electrical training as themselves? If their respective committees think at all about this strange state of affairs, it must strike them that there is some unfairness in paying an assistant who is expected to be able to take the place of the borough electrical engineer in his absence, such a ridiculous fraction of his salary. Of course, the poor fellows have it all so nicely explained to them by the continual humbug, "Look what you are learning." But an assistant cannot continue everlastingly extending his experience for nothing, any more than a borough electrical engineer. In any profession, and especially in that of electrical engineering, a man is learning all his life.

There is no reason for this starving policy even in the case of the few non-paying stations. But it certainly ought not to be seen in a place which pays like Tunbridge Wells. Borough councillors do not expect the officials in their other departments to do work for nothing, and it ought not to be allowed in their electric light station. What would these gentlemen think of engineering firms who pay their skilled mechanics 25s. or 19s. 2¼d. per week? In most tenders a Corporation now expressly stipulates that the men must be paid the standard wage.

If the ratepayers' pockets must be considered in such a remarkable way, and if it is absolutely necessary for the profession that this grinding should go on, might I suggest that permission be obtained from the mayor and councillors of the towns where it is practised for boxes to be placed outside their public buildings with a legend such as this:—

"Electricians' Poor Box.

"As we only pay our assistant electricians enough for board and lodging, we should be glad of your help, so that they may provide themselves, in the interests of decency, with a little clothing. Remember that they work 365 days in the year, and that it is mostly night-work."

Fiat Justitia.

While sympathy for the writers of "Protests" against small pay to *shift engineers* fills my breast, I fail to see that there is sound "horse-sense" in the proposal of W. Fennell. There are dozens ready to pay for a chance at practical electrical experience, and your refusing to accept such advertisements would probably let others try to enter this overcrowded market, who may see these advertisements and be deterred thereby, to our future advantage. I could tell of a small high tension station on this island whose chief engineer and manager accepted the post a few years ago on £2 a week, with the privilege of taking a pupil, and he got the pupil.

L. D. Collins.

Dublin Cables.

Referring to the note on "Dublin Cables" in your last issue, it is evident to me that you are not correctly informed as to the actual facts.

The statement that the arc light cables were too small is entirely without foundation, as 7/16 cable should be perfectly adequate for a current of 10 amperes, and the further statement that it was unsuitable for the mechanical strains it was called upon to bear from time to time is equally incorrect, as no interference was found necessary with these cables until the first breakdown occurred, some three years after the station commenced work.

With regard to your remaining remarks, I may say that the necessity of applying for a loan was due to the fact that the distributing system had repeatedly failed during the previous two years, owing to deterioration of the rubber insulation of the cables at many points, and when as many as 20 failures occurred during one week, it was impossible to preserve the proper continuity of supply to the consumers.

To remedy this state of affairs, it became necessary to lay down new cables; and as these could not be placed in the same pipes with the existing cables without disorganising the supply, it naturally resulted that the ground must be reopened over the whole system to accommodate the new cables, and it was considered advisable to take advantage of this opening to change the system of distribution to the consumers from high tension supply with house transformers, to low tension supply from transformer sub-stations.

When the new system of mains is in complete working order, the existing system of pipes, &c., would be available for use in extensions as required, and such of the cable as should be found suitable would be used for the same purpose.

It is obviously impossible for anyone to know the actual condition of this cable over its whole length until it has been withdrawn and carefully examined; but from the observations I had made I considered that cable to the value of £2,000 should be found capable of being used, out of the total amount of £3,300 which had been expended in purchasing same, and I estimated that the cost of making such cable serviceable should not exceed £500.

In face of the above summary of the recorded facts, I am quite unable to see any foundation for your suggestion of inconsistency, and must request you in future to verify your facts before basing upon them any reflections upon my personal conduct.

M. Ruddle,
Electrical Superintendent,
Dublin Electricity Works.

[We are unaware of having made any reflections upon Mr. Ruddle's personal conduct, and if he will take the trouble to read through the report of the official Government Board inquiry on the city electric light, as published in the *Irish Daily Independent* for December 9th, he will surely admit that his own evidence was sufficient foundation for our note of last week.—Eds. Elec. Rev.]

Estimating, &c.

Could any of your readers inform me of a book on estimating for "mechanical and electrical plant and installation work," or how I could gain some experience of the subject.

A Subscriber.

Royal Institution.—The course of lectures on "Recent Researches in Magnetism and Diamagnetism," which Prof. Fleming commenced at the Royal Institution on March 3rd, are the "Tyndall Lectures."

DUBLIN ELECTRIC LIGHTING.

The following is a copy of the letter from the Local Government Board to the town clerk, conveying the decision of that body on the recent application of the Corporation for a further loan of £20,000, in connection with the existing electric lighting system:—

"Local Government Board, Dublin,
"*January* 13*th*. 1898.

"Sir,—I am directed by the Local Government Board for Ireland to state, for the information of the Corporation of Dublin, that they have received the report of their chief engineering inspector, Mr. Cotton, on the local inquiry, held by him on the 8th ult., into the application of the Corporation for sanction to a loan of £20,000 for works in connection with electric lighting. With regard to this application, the board wish to observe that in November, 1891, a loan of £32,800 was sanctioned for machinery, cables, posts, lamps, &c., for electric lighting, and £4,200 for buildings at the generating station. In November, 1893, a further loan of £16,837 was sanctioned for additional and extra cost of machinery, and £7,563 for cables, pipes, and laying. Of this latter loan only £5,000 was advanced. Recently, it appears, there have been many failures in the cables, and it was resolved by the Corporation to apply for a loan, which, among other things, would provide for laying these cables *de novo*. The Board observe that on September 23rd, 1897, the Electric Lighting Committee recommended that a new generating station should be provided at the Pigeon House Fort, at a cost of £100,000, and also—(2) That a system of sub-transformer stations be adopted. (3) That the entire system of cables or mains, so far as it may be found necessary by the borough surveyor, be altered or renewed. (4) That for the purpose of such renewal the sum of £20,000 be provided. The Council at their meeting on October 8th, adopted a report of the committee of the whole house, slightly varying the recommendations of the Electric Lighting Committee, including the following:—

"'That a system of sub-transformer stations be adopted, as such will ultimately prove a saving to the Corporation: that the entire system of cables and mains, so far as it may be found necessary, be altered or renewed; that for the purposes of such renewal the sum of £20,000 be provided, but that no portion of this amount be expended or orders given, until the description of cable be reported on by the consulting engineer with the borough surveyor to a committee of the whole house, to be called for that purpose, and approved by them; that the Electric Lighting Committee be empowered to apply to the Local Government Board for their sanction to a loan of £20,000, the law agent and the town clerk to take whatever steps are essential for this purpose.'

"On November 10th, 1897, the town clerk wrote to say that the Municipal Council have, on a representation from the Electric Lighting Committee, decided that it is absolutely necessary to have the cables renewed with as little delay as possible, and have therefore directed me to make application for the sanction of your board to a loan of £20,000, to enable the Corporation to proceed with the proposed work. This letter, of course, indicated that £20,000 was required to be spent in re-placing 'cables' which had failed, and the town clerk was informed that a loan to replace failures would not be sanctioned while the loans under which the works were constructed are running. The town clerk wrote again on November 23rd, 1897, to the effect that only a small portion of the £20,000 was required to purchase 'cables' to replace those that failed. Under these circumstances the Board considered it desirable to order the local inquiry, which, as already mentioned, was held by Mr. Cotton on the 8th ult. The town clerk's letter of November 23rd, 1897, and the evidence given at the inquiry, show that the £20,000 is proposed to be applied to two purposes:—1. For forming sub-transformer stations and costs incident on the change of system, say £6,500; 2. For new cables and laying, £13,500—£20,000. From the wording of the report of the committee of the whole house it might naturally be inferred that the whole £20,000 was required simply for the renewal of the cables which had failed. As regards the portion of the loan destined for sub-transformer stations, and costs incident thereon, the Board find that this change of system was recommended by Mr. Ruddle, in his report of September 18th, 1897, and was adopted by the Electric Lighting Committee, and by the committee of the whole house, and approved by the Council of October 8th, 1897. It was also recommended by Prof. Kennedy, in his report of October 25th, 1897, which report the Board are informed, has been approved of by a committee of the whole house. The estimate for this work, contained in the town clerk's letter of November 23rd, 1897, appears to be approximate only. The Local Government Board will be prepared to consider a loan for this purpose when full particulars, specification, and detail estimate are submitted and approved. As regards the rest of the loan which is required for new cables and works in connection therewith, the estimate is also approximate only, and no particulars or specifications have been submitted. The present cables insulated with vulcanised rubber are laid in pipes, and cost, so far as the Board can ascertain—For cables, £3,300; for pipes and road work, £8,000; (about) £11,300. The evidence shows that it would not be possible to draw out the present damaged cables and replace them in the same pipes with new cables without dislocating or stopping entirely the lighting arrangements over the whole area at present supplied. This circumstance, in the opinion of the Board, points to the advisability, in future works, of providing for duplicate mains. There appears, therefore, to be no remedy for the present state of things but to provide new cables, as suggested by Prof. Kennedy in his report, which, as stated above, has been before the committee of the whole house, and approved by them, in accordance with the resolution of the Council of October 8th, 1897. It is stated that the rest of the work, the pipes and works incident thereon, will not be rendered useless, but are available, and will be used for extensions to the further parts of the city outside the present lighting area, and to provide duplicate means of supply as required in consequence of increased demands in future. The Local Government Board consider that a further loan for these cables may be entertained, but the amount should be limited by deducting from the amount required the sum properly outstanding in respect of the portions of the original loans appertaining to the cables which have to be replaced, the cost of which appears to be £3,300, of which about £2,600 is now properly outstanding. The balance (£2,563) of the second loan, not drawn, should be considered as cancelled. The Board do not consider that the suggestion that the present cables can be removed, and when repaired be again used, ought to be taken into consideration. When full particulars, specification, and detailed estimates are submitted and approved, the Board will be prepared to sanction a loan for new cables and works connected therewith.—I am, Sir, your obedient servant,

"(Signed) D. J. MacSheahan,
"*Assistant Secretary.*"

Appointment.—We learn that Mr. William Isaac Taylor, M.I.M.E., of 50, Fenchurch Street, E.C., has been appointed as the successor to the late Mr. Archibald Thomson, to represent the Darlington Forge Company, Limited, for London and South of England, for all work of their manufacture, with the exception of railway work. Mr. Taylor has represented Messrs. Clarke, Chapman and Co., Limited, of Gateshead, for the last 15 years, and this position he still retains.

Art Metal Fittings.—Mr. Charles Escare, of 16, St. Anne's Court, Wardour Street, Soho, send us an illustrated list of various designs of brackets, electroliers, switch covers, &c. Nearly all the designs shown are Louis XV. and XVI., and are exact copies taken from State castles and museums, and adapted for the electric light. The chasing, mounting, gilding and repairing, are carried out at St. Anne's Court.

Bankruptcy Proceedings.—A receiving order was made last week at the London Bankruptcy Court against Trehearne, Son & Crump, electrical engineers, 155, Fenchurch Street, City. Messrs. Montagu & Co. attended on behalf of the General Electric Company, Limited, Queen Victoria Street, the petitioning creditors. The act of bankruptcy alleged in the petition was non-compliance with the requirements of the usual bankruptcy notice. No particulars transpired regarding assets or liabilities.

Brussels Exhibition.—We understand that in addition to obtaining the gold medal at the recent Brussels Exhibition, the jurors have awarded a special prize of 1,000 francs for Geipel's patent steam trap in recognition of its exceptional merits.

Business Announcement.—Messrs. Henderson, Bunn and Co., Limited, of Giltspur Street, announce that they are placing upon the market an insulated iron armoured conduit for electric wiring, the insulation being porcelain enamel. The same firm is also introducing the H.F. dry battery.

Personal.—Mr. Joseph Bastick informs us that he has relinquished his electrical engineering business at Levenshulme, and has joined the Birmingham Carbide Company, Limited, as works manager, on a seven years' engagement, to erect the plant and superintend the manufacture of carbide. Mr. Bastick has been with Messrs. Crompton & Co., Swinburne & Co., John Turner & Sons, and other firms.

Calcium Carbide Plant.—We learn that Messrs. Ashton, Frost & Co., Limited, have on hand a dynamo (60 volts 2,000 amperes) four polar, with slotted drum armature and duplex winding, for the manufacture of calcium carbide in conjunction with Pictet's patent furnace, for Messrs. Carter & Lupton, Ingleton, who hold a license for the Pictet furnaces.

Change of Addresses.—Mr. Geo. Stegmann informs us that, in consequence of increased business, he has removed to larger and more commodious premises at 45, St. John's Hill, Clapham Junction. He will shortly open electric light showrooms, where every requisite relating to electric lighting will be on view.

Mr. J. S. Cunnington, electrical engineer, has removed from 18, Cecil Court, to larger premises, 93, St. Martin's Lane, W.C., in consequence of increased business.

Electrical Plant for Collieries.—During the general meeting of the Federated Institution of Mining Engineers in Newcastle a large number of members and delegates visited the works of Messrs. Ernest Scott & Mountain, Limited, at Newcastle-on-Tyne. The following is a list of electrical colliery plant and other machinery in course of construction and on view in a state of completion, ready for shipment, that was open to the inspection of the visitors:—For the Clay Lane Iron Company.—One set of 14 inches by 18 inches three-throw mining pumps capable of delivering 1,000 gallons per minute against a head of 300 feet. For the Arniston Coal Company.—One set of 14 inches by 18 inches three-throw mining pumps (high lift) capable of delivering 500 gallons per minute against a head of 700 feet. For Messrs. Rowley, Thomas & Co.—One set of 7 inches by 12 inches three-throw mining pumps (low lift) capable of delivering 200 gallons per minute against a head of 250 feet. For the Mitchell Main Colliery.—One set of 10 inches by 12 inches pumps capable of delivering 500 gallons against a head of 150 feet. For the Arniston Coal Company.—Two 200-unit generators for driving pumping machinery, and three 80-H.P. motors for driving pumping machinery. For the Hickleton Main Colliery Company.—Two 90-unit generators for driving electric haulage plant. For Young's Paraffin Oil Co.—Endless rope electric haulage plant with 40-H.P. motor, driven through worm gear. For the Digby Colliery Company.—Electrical coal-cutting machinery, fitted with disc of suitable diameter to cut 4 feet 6 inches deep, and with motor of 30 H.P. For Sir Wm. Gray & Co.—Enclosed compound engine of improved self-lubricating type, coupled direct to "Tyne" dynamo with drum bar armature. Output, 44,000 watts. For Messrs. Walter Scott & Co., for London Central Railway.—Electric locomotive fitted with motor of 25-H.P. and suitable for 2 feet gauge; designed for mines, or for contractors' use underground. For Messrs. Humphreys, Tennant & Co.—Four sets of 20-inch centrifugal pumps and engines combined. For the St. Petersburg Cement Co.—Two 4-foot ventilating fans, with motors combined, capable of delivering 10,000 cubic feet of air per minute at 4 inches pressure.

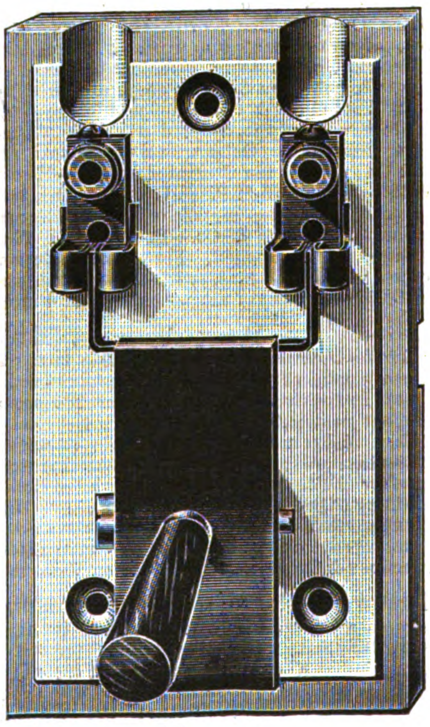
Electrically-Driven Wood Working Machinery.—The *Timber Trades Journal* for February 19th is the twenty-fifth special anniversary issue of that journal. The number is special for several reasons. It consists altogether of over 260 pages of reading and advertisement matter, and the number of special articles got together for the occasion must have entailed an immense amount of work. Our attention is especially drawn to the engineering section, where among other matter we observe a lengthy article on "Wood Working Machinery with direct Electric Driving," in which are shown planer, saw bench, band-saw, boring, and other wood-working tools with electric motors attached. The machines were made and fitted by Messrs. Kirchner & Co., Limited, 118, Queen Victoria Street, E.C.

E.P.S. Batteries.—Mr. J. W. Barnard informs us that his engagement as secretary of Electrical Power Storage Company, Limited, having terminated, the company have appointed him their sole agent in the United Kingdom for the sale of their Q and V types of storage cells. It will be remembered that these types of E.P.S. cells are intended specially for use in connection with carriage, cycle, miners', domestic hand-lamps, phonographs, electro-medical appliances, &c. Mr. Barnard has secured offices at 4, Great Winchester Street, E.C., where he will have every opportunity of meeting the numerous customers of the Electrical Power Storage Company who are interested in this particular branch of its manufactures.

Forthcoming Books.—Messrs. Whittaker will publish immediately "Alternate Currents in Practice," translated from the French of Loppe and Bouquet, by F. J. Moffett, A.I.E.E., electrical engineer to the colony of Lagos, W. Africa. "Electrolytic Methods of Analysis," translated and adapted from the German of Dr. B. Neuman, by J. B. C. Kershaw, F.I.C., and a volume on "Radiography," by S. Bottone, a well-known writer for amateurs upon kindred subjects. The same publishers will also issue, in conjunction with the General Electric Company, "A Popular Guide to Commercial Telephony," by M. Byng, M.I.E.E., and F. G. Bell.

Flannery v. The National Telephone Company, Limited.—In the Queen's Bench Division, before the Lord Chief Justice and a special jury, Mr. J. Fortescue Flannery, M.P. (of Flannery, Baggallay & Johnson), sued the National Telephone Company for damages for breach of contract in failing to supply his house at Norwood with a telephone connection within reasonable time according to the terms of an agreement entered into between the parties. It appeared that in 1893 Mr. Flannery was proposing to stand for Parliament, and in order to be able to attend to his business, which he carried on in the City, as well as to matters connected with his Parliamentary candidature, he thought it would be convenient to have a telephone at his house at Norwood. He therefore communicated with the company, and entered into a contract for connecting his house with an exchange on March 8th, 1893. As there was considerable delay about the matter he complained to the company, and they said that the reason of their delay was that they could not get wayleaves by the route they were proposing to adopt through Streatham. Eventually at the end of May, 1896, the plaintiff's house was connected with the Sydenham exchange. Mr. Flannery said he had been put to great inconvenience by this unreasonable delay, and he brought this action in the interests of the public. The defendants counterclaimed £25 as rental due since the house had been connected, and the plaintiff admitted his liability, and paid the amount into Court. His Lordship asked the jury to consider whether the defendants had taken reasonable and proper steps to carry out their contract, or whether they had been guilty of unreasonable delay. The jury found there had been unreasonable delay on the part of the defendants, and gave a verdict for the plaintiff for £5. Judgment was accordingly given for that amount for the plaintiff on the claim. Judgment was also entered for him on the counterclaim, the defendants to have costs up to the date of payment into Court, and all costs to be on the High Court scale as the case raised an important question.

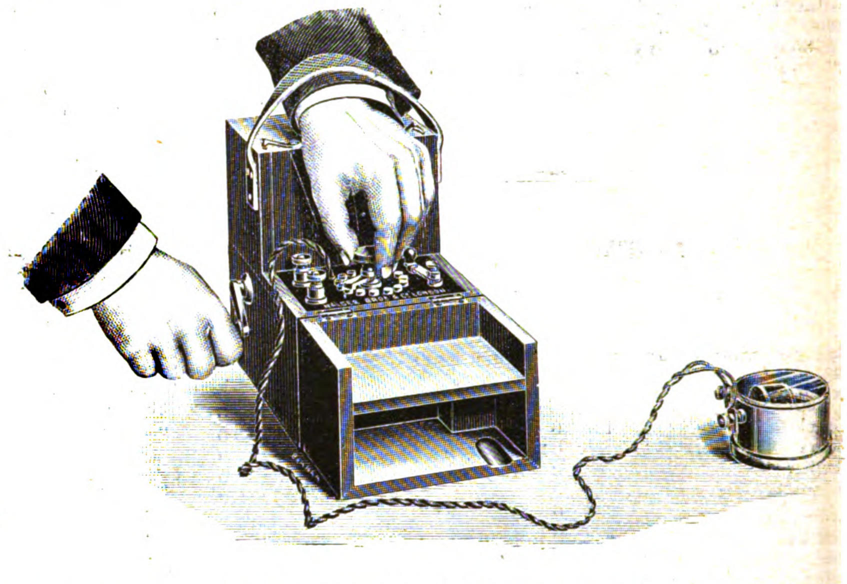
High Voltage Main Switch.—The switch we illustrate below has been designed by Messrs. W. T. Burbey & Co., of Hatton Garden, to meet the requirements of the various central stations and insurance offices for 200-volt supply. In the case of double and triple pole switches, each pole is protected by a



separate china cover, which is fixed by means of a strap and seal on the outside of the switch. The cable connectors are on the front of the switch, as preferred by station engineers, but if a back connection is required, the base is so made that they could be allowed for without extra charge. Front cable connectors are always supplied, however, unless otherwise ordered.

List.—Messrs. Measures Bros., Limited, send us a pocket list, with calendar, giving particulars of their stock sections of steel joists, rails, plates, &c. Numerous tabulated figures are given, showing the breaking loads of cast-iron columns, weights of various sizes of metals, weight per foot of different metals, and other useful notes of a similar kind.

N.C.S. Insulation Test Set and Generator.—We illustrate below the latest pattern of N.C.S. insulation test set. It consists of a 200-volt generator in one case, with Messrs. Nalder Bros. and Co.'s well-known insulation test set. It gives a plain bridge measurement of the insulation under test, thus obviating all errors due to change of magnetism of the needle, or to disturbances from any magnetic bodies in the neighbourhood. The readings depend solely



on carefully wound coils, just as in an ordinary bridge. It reads direct, without calculation, from ·1 megohm up to 50 megohms, with 20 intermediate values. A perfectly sharp difference is obtained between 50 megohms and infinity, and all the other readings are equally sharp. By pushing over a small switch, the readings are all divided by 10; that is, the bridge then reads from ·01 megohm (or 10,000 ohms) up to 5 megohms.

Leicester Corporation v. Warren Hill.—A case of considerable importance to electrical engineers, came on for hearing at the Leicester County Court, on the 24th ult., before his Honour, Judge Wightman Wood, in which the Mayor and Corporation of Leicester, sued H. Warren Hill, electrician, of King Street, Leicester, to recover the sum of £4 19s., in respect of goods sold and delivered. Mr. Simpson, on behalf of the Corporation, stated that so far as the actual purchase was concerned, there was no dispute. The defendant purchased a number of appliances on September 15th, 1895, from the electrical department of the Corporation, but declined to pay for them, on the ground that the Corporation were trading *ultra vires*. There were altogether eight items in the purchase, and in respect of the the first item, 10s. 6d. had been paid into court. The point at issue was whether the Corporation were entitled to sell and recover the price of articles and apparatus, used in connection with the supply of electricity. Mr. Simpson proceeded to quote clauses in the various Acts of Parliament, under which the Corporation supplied electricity, and maintained that they could also deal in apparatus and appliances. Mr. Newell for the defence, said it was a public corporation, and held delegated powers to supply electricity to the public, but it has deviated from those powers, and was selling lamps and appliances, which were not necessarily connected with the supply of electrical energy. They had become traders and shopkeepers, and thereby damaged the local tradesmen, with whom they were unfairly competing. The Corporation, in fact, competed with the local shop-keepers by means of the very rates which the tradesmen partially contributed. His Honour: I suppose this is a case brought on principle? Mr. Newell: Yes, the defendant does not by any means wish to shirk the liability. His Honour: Do you mean to say that under the Charter of Elizabeth, the Corporation has no power to trade. Mr. Newell: I should say that such is the case. Eventually his Honour said he should take time to consider his judgment, as there were important issues raised. Mr. Newell said if his Honour was against him, he should have to appeal, as the Corporation had taken away the bulk of the electrical trade in the town.

Liquidation Notices.—At a meeting of the Crompton-Howell Electrical Storage Company, Limited, held at Mansion House Buildings on January 24th, a resolution was passed winding up the company voluntarily, and appointing Mr. R. H. Marsh, of Ethelburga House, Bishopsgate Street, E.C., liquidator.

A New and Novel Telephone.—Messrs. Henderson, Bunn & Co., Limited, of 15 and 16, Giltspur Street, London, E.C., are introducing a telephone, which will be of interest to many of our readers. It is, perhaps, the smallest and most compact instrument yet produced; at any rate, the patentees claim it to be so. A microphone transmitter and a bell push are fitted into a case, which, when the instrument is not being used to receive or transmit a message, is connected with the receiver in such a way that the two together form a pear shape, quite dust and moisture tight. The receiver is so contrived, that when the transmitter is slipped upon it, a metal nib is pressed, which actuates a Morse key in such a way that the circuits are changed from the microphone and receiver to the bell. When the bell has been rung, the two parts are separated, which act puts the receiver and transmitter into circuit. A braided flexible cord, containing the wires, join up the instruments in such a way, that the receiver may be held to the ear, and the transmitter before the mouth. The internal mechanism is extremely simple, and cannot get out of order and prove ineffective unless the instrument be tampered with. The bell push is likewise upon the Morse principle. Every contact piece is made of platinum; the screws are of brass; the coils cased in, and especial care is given to secure perfect insulation. The ordinary type of instrument is suitable for distances up to 500 yards; beyond this distance an induction coil is used. The induction coil is buried in the rose which carries the bell. The size of the pear over all is 3 inches × 2 inches. Of course, any number of ways may be allowed for, and by means of a line selector, any one of a number of stations may be communicated with. The telephone has been designed with a view to satisfying those who require a portable telephone, small and compact. Each telephone is supplied with about 4 feet of flexible cord. The cases of the instrument are made of vulcanite, with silver plated mounts, the whole presenting a handsome and highly finished appearance.

New Company.—A company has just been registered in Brussels with the title La Compagnie d'Electricité Thomson-Houston de la Mediterranée.

Omnibuses.—In his remarks to the shareholders of the London General Omnibus Company last week, the chairman said that the directors were watching very closely the development of motor vehicles, but as the prime cost of a motor 'bus would not be less than £500 to £600, they did not see their way at present to adopt them. It is interesting to note that the company values its horses at £27 a-piece. Many of them cost between £30 and £50.

Outlet Boxes.—The Ward Leonard Electric Company, of Bronxville, New York, send us a copy of their new catalogue of outlet boxes. We understand that these porcelain-lined boxes have become standard for good wiring work in New York City, and is becoming so in other large cities. The list shows that 81,000 were installed in New York City alone in 1897. The company make outlet boxes of every variety, including a large number of "specials" not shown in the list. Prices and particulars are given.

Presentation.—On 28th ult., a handsome gold watch, with an illuminated address on vellum, was presented to Mr. T. W. Vaughan on his 50th birthday, managing director of Vaughan and Brown, Limited, of Kirby Street, Hatton Garden, and Great Saffron Hill. The presentation was made by members of the staff and old employés, some of whom have been with the firm from 20 to 35 years.

"Specification."—This is the title of a new publication, to appear, revised and enlarged, quarterly. The volume (over 300 pages) is intended for architects, surveyors, and engineers when specifying, and for all interested in building. It is divided into three sections, *i.e.*, construction, professional practice, and buildings in progress. There are some general notes on electric lighting, arc and incandescent, giving particulars of the points to be considered in laying out an installation, and a glossary of English, Irish, and Scotch electro-technical terms is included. There are similar details *re* electric bell work. The price of the publication is 2s. 6d., and it is issued from the office of the *Builder's Journal*, Effingham House, Arundel Street, W.

Westminster Engineering Company v. Kent.—This case came before his Honour Judge Lumley Smith, Q.C., in the Westminster County Court on Friday last. The point in dispute was whether the trade discount should be 10 per cent. or 15 per cent., and whether there should be a cash discount of 2½ per cent. Plaintiffs said their terms in all these cases was 10 per cent., and cash discount was only allowed in some instances, and then only if cash was paid within a month. There was no discount on the wiring, and no special terms were made, and 2½ per cent. was not allowed on estimated work. Mr. Geo. Kent said the question was entirely one of principle. He was a builder, and where he got instructions to fit with electric light, the work was handed over to the plaintiffs for the wiring and fitting, and they always received 15 per cent. on the work done. This had been the custom for many years, and only on three occasions was that departed from, and there were exceptional circumstances in each case. The 2½ per cent. for cash was the custom of the trade. His Honour said he thought the plaintiff was right with reference to the cash discount, and gave judgment for £6 5s. 10d. With regard to the other defendant was right.

Willing's Press Guide.—The 1898 issue (twenty-fifth annual) of this book is before us. It is published by Messrs. Willing, at 125, Strand, (1s.) and contains in easy reference form details of newspapers published at home and abroad, giving the first year of publication, &c. The London addresses of provincial, colonial, and foreign papers are also given.

W. T. Burbey & Co.—With reference to our notice of the dissolution of the partnership of Messrs. Burbey & Hutton, we are asked to state that the business will be carried on under the style of W. T. Burbey & Co. The firm has issued a new catalogue, a copy of which is before us. In it are described and illustrated distributing switch and fuse boards, accumulator plant board, accumulator switches, main switches of various types, cut-outs, tumbler switches, &c.

ELECTRIC LIGHTING NOTES.

Aberdeen.—There was a recommendation of the Lodging House Committee before the Town Council, last week, to accept the tender of Messrs. P. C. Middleton & Co. (£177 odd), for electric wiring of the Corporation lodging house, but the matter was referred back.

The question of reducing the charges for current has been before the Electric Lighting Committee lately, but as the new system of charging has only been in operation for six months, no change is to be made during this half-year.

Bangor.—A Local Government Board inquiry was held on 25th ult. regarding applications *re* various loans, including a sum of £450 for the purchase of an electric light station site.

Barnet.—An electrical firm has offered to take over the District Council's electric lighting order. A committee is considering the matter.

Bath.—The state of the new electricity station was under consideration at last week's meeting of the Electricity Committee. The causes of the various delays were stated, but it was impossible to say when the buildings and the whole of the plant could be ready. Mr. Robert Hammond gave details of the forward condition of some of the machinery and the completion of part.

Bedford.—The Town Council is to purchase two more mechanical stokers at an estimated cost of £385, also two water purifiers in connection with the steam boilers at the price of £120. The electrical engineer is to consider and report as to the practicability and cost of (*a*) installing an electric motor at the water pumping works in place of present boilers now consuming coal, value £500 per annum; (*b*) letting out on hire motors for power, heating and cooking apparatus, with current at 2½d. per unit for certain day hours; (*c*) introduction of prepayment slot meters and wiring houses upon agreement; (*d*) the desirability of applying for powers to construct and work a service of municipal electric self-contained accumulator passenger cars connecting various parts of the town at fares of 1d. At the last Council meeting it was reported that a motor was being installed. Clauses (*b*) and (*c*) were carried, as was (*d*) after discussion.

Consumers were to hold a meeting yesterday to consider the high charges for current.

Belfast.—A sub-committee has been appointed to report on the question of the supply of current for power purposes.

Bradford.—A sub-committee has been appointed to consider the desirability of reducing the price of electricity for lighting purposes. The present charge is 5d. per unit.

Brewery Lighting.—The brewery and business offices of Messrs. George Younger & Sons, Limited, at Candleriggs, are now lighted by electricity. It is stated that the Alloa local authorities have decided to light the principal streets in the same way next winter—cost, £3,000.

Bridlington.—The Council, in reply to a letter from a Sheffield firm, says that it intends applying for an electric lighting order on its own account.

Brisbane.—Mr. Hesketh, electrical engineer to the Queensland Government, in reporting on the proposed electric lighting of Brisbane, states that at first operations should be confined to the main streets of the city, using the direct-current system, with a three-wire distribution at 400 volts.

Buxton.—Prof. Kennedy's report on electric lighting was before the District Council last week. He estimates the cost at £18,000, and recommends a site near the gas works. The Council will hold a special meeting this month to discuss the matter.

Camberwell.—At the last Vestry meeting the General Purposes Committee recommended that notice be given to the County of London and Brush Provincial Electric Lighting Company requiring them to sell their undertaking to the Vestry. The terms were stated to be £133 for every sum of £100 properly expended by the company, and 5 per cent. per annum dividend. After some discussion the recommendation was referred back to the Committee.

Carlisle.—The Carlisle Citadel Station Joint Committee have decided to have the station lighted by electricity. The necessary dynamos and apparatus have been ordered, and the work will be begun at once by the London and North-Western Railway electrical department.

Chelsea.—The Vestry is considering the advisability of purchasing the undertaking of the Chelsea Electricity Supply Company, Limited, forthwith. A committee has power to consult experts.

Coventry.—The annual report of the Electric Light Department shows that the number of consumers increased during the year 1897 from 72 to 100, and the lamps connected from 5,662 (8 C.P.) to 8,149. Further connections are being made. The number of units sold had increased from 51,114 to 79,583, and the revenue from current and meter rental from £1,245 16s. 6d. to £1,958 19s. 8d. The profit on working was £106 2s. 8½d., as against a loss the previous year of £41 0s. 8d. The net charge on the rates was £1,558 7s. 11½d. as compared with £1,706 13s. 8d. the previous year.

Dublin.—The Electric Light Committee is reported to have decided to advertise for tenders in connection with the laying of the new cables for the electric lighting of the city.

Edinburgh.—The Council has accepted the offer of Messrs. Wm Clowes & Sons, Limited, to purchase two engines and dynamos now at the Torphichen Street station for £1,100. These are too small for the Corporation station, and Prof. Kennedy advised the acceptance of an offer. Electric light is to be introduced into the Police Chambers at an estimated cost of £640. A new feeder is to be laid from Dewar Place, along Grove Street, and out to Merchiston at a cost of £1,400.

Edmonton.—The Board of Guardians have referred the matter of electrically lighting the workhouse back to the architect, Mr. Knightley, to obtain plans, specifications, and estimates.

Exeter.—Twelve more electric meters are to be obtained. The clerk is informing the contractors for the electric street lamps that unless they are supplied forthwith in accordance with the contract proceedings will be taken In consideration of the extra work which has devolved upon the assistants and clerk, £30 additional remuneration has been voted for them. A complete return giving the results of 18 months' working, to the end of 1897, shows a gross profit of £1,843. Of this £1,018 goes for interest and sinking fund, £750 is put aside for reserve and £75 is carried forward.

Greenock.—Mr. Teague, in his report as to the electric lighting of Greenock, states that the most suitable site for the installation would be at the Water Trust works at Prospect Hill, and the cost (apart from site) of laying the necessary plant to light the streets from Rue-End Street and along west to Campbell Street, would be probably about £25,000. Mr. Teague will submit a complete report. He recommends a modified scheme, and advises the Board to take up the matter themselves.

Harrow.—Mr. Hawtayne, engineer to the Electric Light Company, recently submitted plans for the extension of the mains down Southill Avenue.

Hartlepool.—The Guardians have decided to obtain a report in reference to the suggestion to light the workhouse by electricity.

Hampstead.—The Vestry Clerk has been instructed to communicate with Messrs Ferranti, informing them that if the new plant ordered is not immediately made available for the purposes of the station, as provided for in their contract with the Vestry, the Vestry will put in force, without further notice, their powers under the contract.

Hoarcross.—An electric light installation has just been completed at Hoarcross Hall and Church for the Hon. Mrs. Meynell Ingram. Messrs. Walker Brothers, of Birmingham, carried out the work.

Hull.—At a meeting of the Electric Light Committee last week the electrical engineer (Mr. Barnard) reported, with respect to the price of current for motive power, that he had been approached by several gentlemen who were considering the question of using the Corporation supply, as to the price charged for current for electric motors. It appeared that the present price of 4d. per unit did not compare favourably with the price charged in Hull for gas for gas engines. He had gone into the question and was of opinion that the price at present charged, namely 4d. per unit, might be very substantially reduced. During 1897, the number of units sold for purposes other than lighting was only 2,550. It was resolved that from March 31st next, the price for current for purposes other than lighting be reduced to 2½d. per unit.

Ipswich.—The Electric Lighting Committee is inviting offers from firms willing to carry out its electric lighting order.

Lancaster.—The Council will borrow £10,000 to increase the plant in the electricity department, so as to double the output.

Leeds—The Parliamentary Committee has decided to recommend the City Council to formally make a definite offer to the Yorkshire House-to-House Electricity Company for their undertaking.

Lewisham.—The Board of Works has resolved not to give its sanction to the proposed scheme of the Great Western Electric Light and Power Company.

London.—The Local Government Board has sanctioned the proposal of the Metropolitan Asylums Board to enter into a contract with Messrs. Crompton & Co., for two dynamos for the *Exmouth*, at a cost of £105 without first advertising for tenders.

The Metropolitan Asylums Board has appointed Messrs. Burstall and Monkhouse, engineers for the electric light installation at the Northern Hospital at a 5 per cent. commission.

The wiring of the new offices of the Court of Common Council Public Health Department is in progress, and the court-room of the late Commission of Sewers and the offices of the engineer are also to be fitted at a cost of £120.

London County Council.—The contract for the electric lighting installation for the Metropolitan Fire Brigade headquarters has been given to the National Free Wiring Company, Limited. The work comprises steam dynamo, storage batteries, incandescent and arc lighting complete. The same firm have also secured the order for the installation of the electric light at the Bridge Hotel, Arundel. The National patent system of house wiring is to be used throughout in both these cases.

Loughboro'.—A committee has been appointed to report on the advisability of taking steps to acquire the gas undertaking, and also to obtain information and report on the question of electric lighting.

Manchester.—Arrangements have been made by the Manchester Corporation with the Moss Side and Levenshulme District Council, by which those districts shall be supplied with electric light at the rate charged to Manchester consumers.

Morecambe.—Mr. Parkinson was recently authorised to instal electric light in the central generating station and the substations.

Portsmouth.—In respect of the proposal to erect a refuse destructor at the electric lighting station, Alderman G. Ellis has reported that there is no land available for the purpose; the boilers at the station could not be used in connection with destructors, and the chimney is not the proper shape. In fact, at present it is altogether impossible to use a destructor at the station. When a new engine house and engines were provided the advisability of building a destructor might be considered.

Sheffield.—The City Council had a brief discussion last week regarding the purchase of the electric light company's undertaking, and in consequence the negotiations will now be completed. It will be remembered they were brought to a standstill by the company objecting to certain statements and insinuations recently made in the Council. In connection with the purchase arrangements Mr. Joshua Wortley, chartered accountant, has examined and reported upon the company's books, and he gives the following note of capital expenditure to December 31st, 1897:—

Capital Expenditure to December 31st, 1897.

			£ s. d.
Electricity Department—			
Land			12,258 9 3
Buildings			14,410 14 9
Machinery and Plant			85,981 7 2

			5,687 8 9
			£124,472 7 5

As recently stated, the company receives £213 8s. for every £100 share originally invested, and in addition £70,000 for stock and stores in hand and recent capital expenditure.

Southampton.—The Sub-electric Lighting Committee reported that the output for December and January showed an increase of 38 per cent. and 36 per cent. respectively over the corresponding periods of last year. At a recent County Council meeting Mr. Manville read a report on low tension mains to be laid in connection with the high tension system outside the centre of the town. In view of the probability of the house connections becoming numerous in many streets, and also of the advisability of making a supply in further streets or roads adjoining those already decided upon, he suggested that it would be advisable to lay low tension mains at once from which to supply consumers, and place large transformers in street boxes, feeding into these low tension mains in place of small isolated ones on the premises themselves. He had conferred with Mr. Lee, and they had picked out those streets which are likely to prove the more remunerative in the immediate future, and in these streets and roads he proposed that a low tension concentric main should be laid. In addition to these streets and roads he would propose that a low tension main be drawn into the ducts already laid to carry the high tension feeder and the tramway feeder, with one spare duct in the other stated streets. The total cost would be £3,500. The Electric Lighting Committee recommended the Corporation to lay additional mains in various streets, &c., at a cost of £4,000, and to apply to the Local Government Board for sanction to borrow the amount; also that application be made to borrow the amount required for various works already sanctioned by the Council, and in addition to the sum of £54,000 previously sanctioned by the Local Government Board. As to public lighting, Mr. Manville reported that the position for the arc lamps should be largely guided by the necessary position for the standards carrying the trolley wire for the tramways. He suggested that he should be given power to lay out the position of the new tramway lines, in order to be able to fix the position of the standards carrying the trolley wire, which could then be ordered, together with the requisite materials for the public lighting. Mr. Manville was instructed to submit report and plans upon the proposed position of the standards, to carry both the trolley wire for the tramways and the arc lamps for public lighting along the route of tramways. He reported that the first alternator will be delivered and set to work by May 30th, the second by June 16th, and the third by July 7th. The motor-alternator on June 6th, and the two new continuous current dynamos on July 5th and 26th respectively. As to the high tension switchboard, the Committee recommended the Council to procure a high tension switchboard from Messrs. Ferranti, at an additional cost of £314 (£714 in all), and apply to the Local Government Board for sanction to borrow this amount. They also recommended that the tender of Messrs. Pritchetts & Gold be accepted in substitution for the tender of the Chloride Electrical Storage Syndicate, Limited, for accumulators. For the supply of from 150 to 200 tons of large steam coal the tender has been accepted of Messrs. E. T Agins & Co, at 16s. 9d. per ton. The committee instructed Mr. Manville to submit a report and plans. The committee's report was adopted by the Council.

Southborough.—The District Council will oppose the application of Mr. D. E. McKrell, of Little Mowhurst, Edenbridge, for a provisional order.

Stirling.—Prof. Kennedy has submitted a further report to the Town Council *re* the water power at Touch in connection with proposed electric lighting. He finds the maximum theoretical hydraulic H P. coming into Stirling at 40. The actual amount of this H P. in the mains for supplying light would not be more than half this. The total H.P. provided for in Prof. Kennedy's steam-power estimate was 320, which would deliver at least 233 electrical H P at the lamps. The total cost of this plant would be between £8,000 and £8,500 If turbines and dynamos were put down at Touch, at least £1,600 would have to be spent, and probably considerably more, to deliver about 15 H.P. at the lamps. The capital expenditure on this power would, therefore, be about £107 per H.P. at the lamps, as against about £35 for the steam plant.

Sunderland.—The Lighting Committee has presented a report on electric lighting extensions. Mr. Snell, the electrical engineer, says that further extensions are necessitated by the increased demand. Looking ahead, he estimates that to meet the requirements up to 1901, £12,728 would be required for buildings, boilers, and dynamos, tools, &c., and a further £12,540 for mains and such like. Immediate requirements would be met by £7,800. Application to the Local Government Board for leave to borrow not less than £25,000 is suggested. With this sum it is thought that all the districts in the borough can be served. Mr. Snell estimates that in the first year the profits would be £105, in the second, £760, and in 1901, £1,370.

Swansea.—The Sub-Electric Lighting Committee had a conference with Mr. Manville on Saturday *re* electric lighting. Mr. Manville recommended low tension for the present scheme, and will at once prepare a report. There was practical unanimity as to proceeding with the scheme immediately. The question of a dust destructor was discussed.

Swinton.—Mr. Scott Anderson is to advise the Urban Council on the matter of electric lighting.

Trinidad.—A Liverpool paper says Mr. J. Stanley Richmond, who has had a good deal of experience with English and American houses, has secured the appointment of electrical engineer to the Government of Trinidad to examine and report upon the various systems—light, power and telephone—using electric currents in Port of Spain and its vicinity, with a view to determining the risk to life and property now involved.

Wakefield.—On Tuesday last week the New Municipal Buildings for the County Council of the West Riding of Yorkshire, were opened. These premises, which have cost about £130,000, have been fitted up for the electric light by Mr. T. Harding Churton, of Leeds; there are in all about 1,100 lights, all the wiring being carried out in insulated conduit, the distribution being effected by the switch and fuseboard plan. All the electroliers have been specially designed by the architects, and are of a most artistic character. The light was on for the opening and gave great satisfaction. The buildings are fitted throughout with a complete telephone installation. There are five exchanges in the building, all being connected by "up" and "down" trunk lines. All the wires, which have been run in iron conduit, are metallic circuit. This work has been carried out by the Private Wire and Telephone Installation Company. All the electrical work has been under the direction of Mr. Sidney à Court, A.M.I.C.E., of Victoria Street, S.W.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Ashton.—The Council will oppose the Bill of the Manchester Carriage Company on various grounds, one being that it is calculated to prejudice the Corporation's power to purchase the tramways three years hence. The Corporation already has electric lighting powers, and, therefore, objects to the company having similar powers.

Bordeaux.—The report of the Bordeaux Tramways and Omnibus Company for the year 1897, says that the question of electrical traction has received constant attention from the directors during the past year, and after lengthy negotiations they succeeded in coming to terms with a committee of the Bordeaux Municipal Council appointed for the purpose. Since the end of the year, however, the Council has rejected the committee's report by 18 votes to 15. The directors, whilst regretting this decision, feel that they have gone as far as they prudently can in their endeavour to meet the views of the municipality without prejudicing the position and interests of the shareholders.

Bournemouth.—The electric tramway schemes which were being promoted here will now fall through. The Light Railway Commissioners have held a lengthy inquiry at Bournemouth with respect to applications by two electric tramway companies to construct lines connecting Bournemouth with Poole and Christchurch. Strenuous opposition was offered by Bournemouth Town Council to any tramways being laid within the borough. The Commissioners, over whom the Earl of Jersey presided, decided that no public necessity had been proved to induce them to overrule the decision of the Council or to authorise any remaining portions of the two schemes which lay outside the borough.

Brighton.—The Bill for the construction of an underground electric railway from the Brighton terminus to the sea front passed the second reading in the House of Lords last week.

Bristol.—Controversy between the Bristol Tramway Company may still be regarded as acute, but citizens have an impression that possibilities of a settlement are nearer. In a speech to the company's shareholders the Chairman of the company criticised the assumption of the Sanitary Committee as to the extent of the saving which electricity made possible in working expenses, and declared as the result of their experience the working expenses of electric traction cannot be reduced below 60 per cent. of the receipts. These figures were important, bearing in mind the allegation of the Sanitary Committee that electric power would enable the company to reduce fares and to pay a royalty to the Corporation. The civic electrical engineer, Mr. Faraday Proctor, included this subject in the report in which he embodied information derived from his visit to Liverpool, Manchester, Bradford, Leeds, and Sheffield. He took, as the result of figures he has supplied to the committee in reports which have not been made public, 4½d. per car mile as the total cost of working trams in Bristol should electricity be applied. That this amount was ample was, he said, shown by figures of other towns. When the Bristol company had one line working by electricity they stated that the cost was found to be 5½d. per car mile, as compared with 9½d. for horse cars, and in this case plant was "admittedly badly arranged." Thus, according to the company's own showing, the cost was only 41·67 per cent. of the electric car receipts. In a supplemental note the engineer again referred to the plant, and termed it "an absurd arrangement of engines and dynamos coupled together by ropes for driving purposes." Better engines than those in question did not exist when they were properly used, but the Tramway Company threw out the whole plant, and put in fresh. A great expense had been incurred, and it ought to have been, and doubtless was, charged to revenue. This, he suggested, might have raised the cost of working, and he asked suggestively if the cost of the advertising, circularising and printing on behalf of the company during the controversy (the propaganda has been very extensive) has not also been charged to revenue, so as to raise the working cost. Basing a calculation on the 4½d. per car mile for electric traction, as compared with 9½d. for horse cars, Mr. Faraday Proctor pointed out that on the mileage for the year ended June 30th, 1897, the company would make an additional profit of £36,380 by the adoption of electricity. This would be altogether apart from the probable increase of traffic. The secretary to the company, Mr. Sam White, in reply denied that the company ever stated that they found the cost of electric traction 5½d. per car mile as against 9½d. for horse traction. "This assertion is absolutely untrue," said the company's representative, "no such statement has ever been made, and the two figures named are incorrect." He challenged the Electrical Engineer to name any place in the Kingdom which justifies the statement that 4½d. per car mile for electric traction can be taken as the total cost. The Engineer's estimate of the cost of the trolley system meant that working expenses would be only 35·29 per cent. of the receipts, a ratio unheard of amongst tramway men for the operation of any tramway in the world. Mr. White then alluded to the information given by Mr. Faraday Proctor with regard to the working in northern cities, and said its "fragmentary and unreliable character is perhaps excusable, seeing that he himself tells us that having received the Committee's instructions on Monday he was able to visit Liverpool, Manchester, Bradford, Leeds and Sheffield, and return to Bristol in time to prepare his report on the subsequent Friday." Mr. White concludes his letter by stating that he considered it undesirable to reply upon the general tone of this report, or the "offensive innuendos as to the company's management." The Tramway Company has also replied to the Corporation upon the terms submitted and reported in last week's ELECTRICAL REVIEW. The company do not consider the Corporation justified in seeking to impose conditions as to the terms of employment of the tramway men, and give figures to show the Bristol men are well treated already. The company see no objection to the tramways to be worked electrically being specified in the Bill; they agree to the Corporation control over streets and works being as under the Act of 1894; they agree that the company shall not supply electricity to others, or that the company shall not require the Corporation to supply them with electricity. They agree also that the company's posts shall be usable by the Corporation for electric lighting standards, although they regard this as equivalent to a gift to the city of £10,000. They contend that the purchase of lines by the Corporation must be coupled with purchase of the company's power station, as the two cannot be severed, and when the purchase takes place the company will arrange for working any tramways outside the city which may have been operated from that power station. The company do not seek to disturb the existing periods for the purchase of the west horse lines by the Corporation, but drafted the Bill on those lines, not contemplating the Corporation imposing additional and exceptional obligations on the company, and if such obligations are imposed they could only be undertaken if accompanied by an agreed extension of the purchase period. The company do not propose to proceed with their extensions Bill unless under the terms of 21 years' purchase contained in the Tramway Act. The company refuse to consent to the issue of new capital by auction, but are prepared to discuss the payment of an annual sum to the Corporation and the reduction of fares, if an arrangement is arrived at for fixing the period of purchase of all the company's tramways within the city of Bristol at one uniform date—25 years.

It is reported that in the last few days a body of motor-men of the Bristol Tramway Company (said to be 25 in number) have taken part in an agitation for improved conditions of employment, and have been dismissed from their situations.

Chiswick.—A poll of this district is to be taken to ascertain the feeling in regard to the electric tramway scheme of the London United Tramways Company.

Clontarf.—The work of laying the electric cable for the Clontarf tram line to Nelson's Pillar was commenced last week by Messrs. Porte, Sykes & Co., of Dublin.

Collision.—One of the Dublin electric cars collided with a cart one day last week and did considerable damage to both conveyances, at the same time seriously injuring the car driver.

Dalkey.—The Dalkey Town Commissioners will send witnesses to support the Bill now being promoted by the Dublin and Southern Districts Tramway Company to amend the provisions of their 1893 Act, relating to the speed of cars on the company's line. The witnesses will give evidence that the residents of the townships at large consider the present speed at which the cars are allowed to travel, far too slow.

Dover.—The contractor for the permanent way of the electric tramway was fined by the Corporation £2 per day from July 16th to December 10th (£254 total), for delay in completing the contract.

Dortmund.—The Allgemeine Lokal and Strassenbahn Gesellschaft have got out the plans for a normal-gauge light electric railway to run in connection with the Dortmund street railways. The light railway will be adapted for passenger traffic, and will run from Dorstfeld by Marten to Lütgendortmund.—*Elektr-Rund.*

Edinburgh.—The Lord Provost's Committee had before them last week the report by Prof. Kennedy on the proposed conversion of the Portobello tramways. It dealt with the arguments for and against electric traction and cable traction, and, it appears, gave great consideration to the objections of the lessees to electricity. The report was delayed.

Electric Carriages in Berlin.—The *Elektrotechnische Zeitschrift* of February 24th contains an illustrated description of two types of electric carriages which are being demonstrated in the streets of Berlin. These carriages, which have been built by one of the leading cycle companies, are fitted with bicycle wheels and pneumatic tyres, which can be inflated to a pressure of 120 lbs., whilst the bodies are supported on steel tubular frames. The wheels have ball bearings, and steering is effected by means of a lever connected with the front pair of wheels. Each carriage is equipped with a motor suspended from a steel frame lying parallel with the rear axle, the latter passing through the hollow armature shaft, and being driven by differential gearing from a toothed wheel arranged on that shaft. The battery consists of 44 cells contained in four boxes, the total weight being eight cwts. It can be charged at a pressure of either 65 or 110 volts, and the connections allow of four different speeds being attained, three by altering the disposition of the battery, and one by weakening the motor field. The carriage is provided with a watt-hour meter, which indicates the condition of the battery, and the total weight complete is 16 cwts. It is possible to attain a speed of 12 miles an hour, and one charge will allow of the carriage covering a distance of 27 miles before the cells require to be re-charged. The carriages possess a pleasant appearance, having been built specially for the work.

Electric Water Vans.—The Clerkenwell Vestry recently referred to the Works Committee to report on electric watering vans, but the committee say that they are unable to report, as they cannot ascertain that there is such a van in existence.

Great Orme's Head.—The Llandudno District Council held a special meeting last week to consider steps to be taken in regard to the proposed application to Parliament by a company for an Act to construct an electric tramway from Llandudno to or near the summit of Great Orme's Head. The terms regarding purchase by the municipality were amended.

Gateshead.—The directors of the Tramway Company in their report say that, as the shareholders are aware, an agreement has been entered into between the company and the British Electric Traction Company, Limited, which was unanimously accepted at the extraordinary meeting held on December 9th last. The scheme is now under consideration by the Gateshead Corporation and the Felling Urban District Council, whose consents are necessary before the arrangement come to can be carried into effect. Under the terms of the agreement made with the British Electric Traction Company, Limited, a director of that company is to be elected an additional director of this company, and the directors propose that Mr. Emile Garcke, managing director of the British Electric Traction Company Limited, be so elected.

Light Railway.—The Beaumaris Town Council is doing everything possible to help forward the construction of the proposed light railway from Llanfair P.G. to Beaumaris.

Hagen.—The Hagener Strassenbahn Aktien Gesellschaft is about to build, in connection with the Hagen street railway terminating at Haspe, a narrow-gauge electric light railway for passenger traffic, from Haspe to Gevelsberg.

Motor Cars in the Army.—It is stated that the Royal Engineer Committee of the War Office has appointed a sub-committee of its members to consider the adaptibility of motor cars for purposes of army transport.

Manchester.—The City Council met on Wednesday to consider the recommendation of the Special Committee *re* the working of the tramways, and to consider the necessary measures to be taken for promoting a Bill to enable the Corporation and any neighbouring local authorities to make arrangements for working their tramways in conjunction with those of Manchester, the powers to include the supply of electricity by the Corporation, or by any local authority, for working tramways in the district of such local authority.

Norwich.—The Council has, on the recommendation of the Tramway Committee, laid before the Norwich Electric Tramways Company a note of its requirements respecting the roads to be traversed by the electric tramways. Some of the roads will be paved with wood and others with granite setts.

Rome.—The question of the conversion of the present tramways into electric tramways has now for some months occupied the attention of the municipal authorities, especially since the new electric lines from Piazza San Silvestro to the station and Sant Agnese, as well as that from Piazza Venezia to San Giovanni and San Paolo, have not only been extensively used, but have also paid a good return on capital. In the Municipal Council a strong opposition to the overhead conductor has gradually arisen, and there the matter rests. Accumulator traction would be the best solution of the difficulties, but all systems hitherto have failed on account of the weight of the accumulators (3,000 to 4,000 kg.), which makes it impossible to run on steep inclines or sharp curves. The Societá Italiana di Elettricita of Turin put itself, therefore, in communication with the Roman tramway company, with the view of testing the invention of a colonel of engineers, named Pescetto, which professes to reduce the weight of the accumulators to one-half. Recently the official test was made. A car with the new accumulators ran from the Quartier Ludovisi to the church of Sant Agnese, in front of the Porta Pia, and back, and took all the curves and gradients with ease. The officials of the tramway company celebrated in a suitable manner this remarkable success of an Italian invention, on Italian soil, and supported by Italian capital.—*Elektr-Rund.*

The Life of a Tramway Wheel.—At a Board of Trade inquiry, held on 24th ult., into the recent tram accident on the Sparkbrook route, Birmingham, when a car overturned, it transpired that the cause of the accident was a broken wheel of the back bogey, which brought about derailment. The particular wheel which was broken, was, according to the company's engineer, attached to the car last September. It was then 20 11/16 inches in diameter. When taken from the car after the accident it measured only 19 inches in one direction, and 18 11/16 inches in another. The flattening was attributed to skidding when the brake was put on. The inspector (Col. Yorke) made close inquiries as to the quality of the wheel. He was informed that it was one of the best-known makes—Miller's, of Edinburgh—and that it was of average hardness, although it had worn very badly. The life of a tramcar wheel, said one of the witnesses, was about ten months. They were calculated on the average to run 20,000 miles. This particular wheel had probably covered 10,640 miles, at the rate of 72 miles per day. The loss of a couple of inches in its diameter in so short a time was attributed to the great friction which the sludge had set up on the rails—friction which, according to one witness, was nearly as great as that of a grinding stone.

The Power Distribution Schemes.—In connection with one of the large power schemes to which we have several times referred, we understand that a Bill has been introduced into Parliament, under which it is proposed to incorporate a company by the name of the "General Power Distributing Company." Upon this company Parliament will be asked to confer power to erect a central generating station at Stockholme, Nottinghamshire, from which electricity will be conveyed throughout the proposed area of supply. This area is defined in the Bill to be "so much of the counties of Derby, Nottingham, Lincoln, and Yorkshire as is contained within a radius of 25 miles from the north-west corner of the Parish Church of Warsop, in Nottinghamshire," including all cities, county and other boroughs, towns, villages, urban and rural districts within that area. The share and loan capital of the company is proposed to be £1,000,000, of which £750,000 will be in £10 shares, and £250,000 will be raised on debentures. The promoters of the Bill are Sir Thomas Thompson, Bart., Mr. William McArthur, Mr. Ernest Lazarus, and Mr. Albert B. Monks, who, with six other duly qualified persons to be nominated by them, are to be the first directors of the new company.

Lincoln City Council is among the latest bodies to decide to oppose the General Power Distributing Company's scheme.

At a meeting of the Wolverhampton Town Council, on Monday, a letter was read from Mr. Addenbrooke, engineer to the Midland

Corporation for Electrical Power Distribution, Limited, asking the Town Council to reverse their decision to oppose the scheme. Ultimately a resolution was proposed to the effect that the letter be referred to the General Purposes and Lighting Committee for consideration. On being submitted to the Council, however, the resolution was rejected by 24 votes to 16.

Rotherham will oppose the General Power Distribution Company's scheme, as it is hoped to go in for municipal electric lighting shortly. Rowley Regis will support the Midland Company's scheme conditionally.

TELEGRAPH AND TELEPHONE NOTES.

Australian Telegraphs.—In the House of Commons on Tuesday Mr. Hogan asked the Secretary to the Treasury whether he was aware that telegraphic communication with Melbourne and Sydney had repeatedly been interrupted during the past five months; who was responsible for the satisfactory maintenance of the Australian trans-Continental telegraph line on which the interruptions occurred; and whether any steps could be taken by Her Majesty's Government to prevent these repeated failures of communication. Mr. Hanbury, in reply, said the interruptions mentioned in the question have occurred on both the trans-Continental lines. These are maintained by the South Australian and Western Australian colonies respectively. Her Majesty's Government is not in a position to take any steps to prevent the failures of communication, which are, it is understood, caused by storms. The cable companies have, however, put forward a scheme, in connection with the question of an alternative cable service, for taking a cable direct to a point near Adelaide, and this will no doubt be duly considered by the colonies concerned.

Bedford Telephones.—The Postmaster-General has replied to the Corporation that as the Select Committee of the House of Commons appointed to consider the matter has not yet reported, he cannot entertain the application for a municipal license.

Cable Repair.—The Great Northern Telegraph Company's steamer, *H. O. Orsted*, succeeded on Wednesday last week (says the *Buchan Observer*) in repairing the damaged Norwegian cable between Peterhead and Bergen. The damaged part was found about 35 miles from the Aberdeenshire coast. For some years past the cable has been frequently destroyed and broken, entailing a great deal of expense to the company. The belief is entertained that the damage is attributable to trawlers, who either cut or otherwise injure the cable in the course of their trawling operations.

French Telephones.—Telephonic communication is now established between Paris and several towns in the south-west, including Dax, Pau, Bayonne, Biarritz, and St. Jean de Lux.

Some Causes of Delay in Australian Telegrams.—The following is an extract from an Australian paper dated January 13th.—"*Interruption of Cables.*—The Postal and Electric Telegraph Department has been advised by the Postmaster-General of South Australia that the Eastern Telegraph Company notify an interruption to one of their Mediterranean cables, and the Persian Gulf station reports the cutting of Mekran landlines. Some delay to European traffic is, therefore, likely to accrue therefrom." We also read the following in the *Sportsman* of March 2nd:—"Australian wires have been simply blocked by the cabled reports of the test games, causing delay, except to those forwarded at urgent private rates, *i.e.*, 14s. per word, instead of the ordinary press rate, 2s." *Observer* adds:—"The fight between the representatives of the big cable syndicates to get first on the wire at the fall of a wicket is like the rush of war correspondents when a big battle is being fought, and one company will spend, probably, £3,000 in cables over the five test matches. Who says cricket is simply a sport?"

The Telephone Service.—The Court of Common Council is sending a copy of the arguments and judgment in the recent action between the G.P.O. and the Commission of Sewers, to every municipality in the United Kingdom, as well as to the metropolitan vestries and boards.

CONTRACTS OPEN AND CLOSED.

OPEN.

Belfast.—March 8th. The Corporation wants tenders for the wiring of the new police cells, Chichester Street. Electrical engineer, Mr. V. A. H. McCowen. See our "Official Notices" February 18th.

Belgium.—April 1st. The Municipal Authorities of Seraing are inviting tenders for the concession for the supply of electrical energy in the town for public and private lighting purposes during a period of 30 years. Particulars may be had from, and tenders to be sent to, the College des Bourgmestre et Echevins, Seraing, Belgium.

Berlin.—March 15th. The Municipal Traffic Deputation of the Town Council has opened a competition for the construction of several new electric tramways in that city. Exhaustive details concerning this project are contained in the *Elektrotechnische Zeitschrift* of the 13th inst., which mentions that proposals will be received by the Stadtische Verkehrsdeputation Rathhaus III, Berlin, by March 15th.

Blackpool.—March 22nd. The Corporation wants tenders for a tubular boiler, superheaters, condensers, rectifiers, boosters, transformers, lead-covered cables, arc lamps and pillars. Borough electrical engineer, Mr. R. C. Quin. See our "Official Notices" February 25th.

Bolton.—The Bolton School Board is inviting tenders for the supply of six electrical clocks. Specifications can be obtained from the Clerk to the Board (Mr. G. R. Rothwell).

Coventry.—March 8th. The Electric Light Committee wants tenders for the supply and erection of engine house, separate exciting and surface condensing plant, also pipework, switchboards and instruments for extensions of the municipal electricity works. Consulting engineer, Mr. Robert Hammond. See our "Official Notices" February 18th.

Denmark.—March 12th. Tenders are being invited for the supply of the engines, dynamos, accumulators, &c., required in connection with the new central station at Frederiksberg, near Copenhagen. Tenders to be sent to the Frederiksberg Sporveis-og Electricitets Aktieselskab, Gammel Kongevie, 140, Copenhagen V., from whom particulars may be obtained.

Derby.—March 24th. The Corporation wants tenders for the electric wiring of the Lunatic Asylum and premises at Rowditch. See our "Official Notices" this week.

Devizes.—March 21st. Tenders are wanted for the supply and delivery of two 40 kw. continuous current belt-driven dynamos for the Wilts County Asylum, Devizes. Engineers, Messrs. Massey & Allpress, 25, Queen Anne's Gate, Westminster. See our "Official Notices" this week.

Edinburgh.—The City Council is inviting tenders for a host of stores and sundry articles. Among the items are "electric lighting materials for the Powderhall destructor," and "upholding of electric light installations." Particulars, &c., from the electrical engineer, Dewar Place.

France.—March 31st. Tenders are being invited by the Municipal Authorities of Saint Chamond (Loire) for the concession for the lighting of the public streets of the town, either by gas or electricity. Particulars from, and tenders to be sent to, La Mairie de Saint Chamond (Loire).

Liverpool.—March 8th. The West Derby Board of Guardians wants tenders for supply and erection of boilers, engines, dynamos, batteries, wiring, &c., for the lighting of the Mill Road Infirmary. Consulting engineer, Mr. T. L. Miller. See our "Official Notices" February 25th for particulars.

Manchester.—March 15th. The Great Central Railway Company (M. S. & L.) want tenders for the supply of various materials and stores during 12 months ending April 30th, 1899. Among the items are asbestos packing, brass sheet and tubing, electrical materials, India-rubber, tin and zinc sheets, wire, &c. Particulars from Mr. A. W. Longden, storekeeper, at Junction Street Mills, London Road, Manchester.

Northwich.—March 5th. The Weaver Navigation Trustees are inviting tenders for the construction and erection of the necessary electric power plant for lighting and working the new swing bridges at Northwich. Current will be supplied by the Northwich Electric Supply Company. Engineer, Mr. J. A. Saner, M.I.E.E. See our "Official Notices" February 11th.

Pembroke (Ireland).—March 5th. The Lighting Committee wants tenders for the supply and erection of various plant, machinery, &c., for electric lighting. See our "Official Notices" February 18th for full particulars. Consulting engineer, Mr. Robert Hammond.

Plymouth.—March 23rd. The Corporation wants tenders for the supply of alternating current meters for the year ending March 31st, 1899. Particulars from Mr. J. H. Rider, Borough electrical engineer, East Street, Plymouth.

Roumania.—March 15th. Tenders are being invited by the General Direction of the Roumanian Post and Telegraphs in Bucharest for the supply of 56,000 metres of galvanised iron and steel wire.

Shoreditch.—March 8th. The Vestry wants tenders for the supply of electric cables and sundries, also engineers' tools, ironmongery, &c. See our "Official Notices" February 18th.

Southampton.—March 7th. The Corporation invites tenders for the supply of stores and fittings required in the electric light department during a period of 12 months. Tenders to the Town Clerk.

Southgate.—March 14th. The District Council want tenders for an installation of electrical communication for fire brigade purposes. Surveyor, Mr. C. G. Lawson. See our "Official Notices" this week.

Switzerland.—April 30th. The Government Authorities of Fribourg (Switzerland) are inviting plans and estimate for a projected electricity generating station of about 6,000 H.P. capacity to be established at Hauterive, where water power is available. A premium of 3,000 francs (£120) will be awarded to the three best schemes sent in. Particulars of the competition may be had from the Départment des Travaux Publics, Fribourg, Switzerland, to whom all plans, &c., are to be sent not later than April 30th next.

The War Office.—April 27th. The Secretary of State for War is prepared to receive offers, competitive designs and specifications for the supply of portable electric search light apparatus. Particulars from the Director of Army Contracts, War Office, Pall Mall, S.W. See our "Official Notices" February 4th.

Victoria.—March 21st. The Telegraph Department of the Victorian Government Railways is inviting tenders for the supply of alternating current transformers and one main switchboard. Tenders to the Telegraph Superintendent's Office, Spencer Street, Melbourne.

Wallasey.—March 17th. The District Council wants tenders for the supply of engine, alternator, exciter, two Lancashire and one water-tube boilers, and condensing apparatus. Engineer, Mr. J. H. Crowther. See "Official Notices" February 11th.

Watford.—March 16th. The District Council wants tenders for the supply and erection of various plant for the electric lighting of the district. For details of the seven sections see our "Official Notices" February 11th. Mr. W. C. C. Hawtayne, consulting engineer.

West Ham.—March 8th. The Council invites tenders for wiring and fitting up various buildings, including the Town Hall, police court, Corporation stables, fire stables, &c. Mr. J. Steinitz borough electrical engineer. See our "Official Notices" February 18th.

CLOSED.

Gloucester.—The following is a list of tenders for the supply of plant and machinery for the municipal electricity works of the city of Gloucester. Consulting engineer, Mr. Robert Hammond. The Council accepted the tenders at its meeting on Tuesday.

SECTION A.

Boiler House Plant.—Lancashire boilers and accessories, mechanical stokers, feed pump, injector, economiser, electric motor.

Name of Firm.	Make of Boiler.		Amount of Tender.
Yates & Thom	Yates & Thom	(accepted)	£2,409
Tinkers, Limited	Own make		2,478
E. Danks & Co. (Oldbury), Limited	E. Danks & Co. (Oldbury), Limited		2,478
India-Rubber, Gutta-Percha and Telegraph Works Company, Limited	J. Adamson & Co.		2,558
H. T. Danks, Limited	Own make		2,590
Holdsworth & Sons	"		2,665
Henry F. Joel & Co., and Thos. Potter & Sons, United, Limited	Yates & Thom		2,821
John Fraser & Son	Own make		2,910

SECTION B.

Engine House Plant.—Steam Dynamos and Accessories.

Name of Firm.	Make of Engine.		Amount of Tender.
C. A. Parsons & Co.	Parsons turbine		£4,570
India-Rubber, Gutta-Percha and Telegraph Works Company, Limited	Belliss	(accepted)	5,917
Siemens Bros. & Co., Limited	Sisson & Co.		6,495
Easton, Anderson & Goolden, Limited	Willans		6,585
Crompton & Co., Limited	Sisson & Co.		6,614
Siemens Bros. & Co., Limited	Belliss		6,720
Electric Construction Company, Limited	"		6,753
Crompton & Co., Limited	Sisson & Co.		6,820
Henry Joel & Co., and Thos. Potter & Sons, United, Limited	Willans		6,882
Thos. Parker, Limited	Belliss		6,980
Laurence, Scott & Co., Limited	Willans		6,994
Electric Construction Company, Limited	"		7,035
P. R. Jackson & Co., Limited	Belliss		7,052
Siemens Bros. & Co., Limited	Willans		7,060
Crompton & Co., Limited	Belliss		7,402
W. Sisson & Co.	Sisson & Co.		7,415
Crompton & Co.	Willans		7,640
Brush Electrical Engineering Company, Limited	"		7,749
J. C. Howell, Limited	"		7,752

SECTION C.—*Overhead Travelling Crane.*

Bedford Engineering Co.,		£240
India-Rubber, Gutta-Percha and Telegraph Works Company, Ltd.		262
James Spencer & Co.	(accepted)	265
Marshall, Fleming & Jack		267
Humpidge, Holborow & Co., Limited		285
Carrick & Ritchie		306
Henry F. Joel & Co., and Thos. Potter & Sons, United, Limited		310
Summers & Scott		315

SECTION D.—*Switchboard and Instruments.*

James White		£1 074
Nalder Bros. & Thompson	(alternative)	1,083
Edison & Swan United Electric Light Company, Limited		1,093
Crompton & Co., Limited	(accepted)	1,111
Nalder Bros. & Thompson		1,190
Williamson & Joseph, Limited		1,211
P. R. Jackson & Co., Limited		1,265
Veritys, Limited		1,275
General Electric Company, Limited		1,300
Ernest F. Moy, Limited		1,318
Electric Construction Company, Limited		1,357
Henry F. Joel & Co., and Thos. Potter & Son, United, Limited		1,393
Siemens Bros. & Co., Limited		1,530
India-Rubber, Gutta-Percha, and Telegraph Works Company, Limited		1,555
Burbey & Hutton		1,559

SECTION E.—*Accumulators.*

Electrical Power Storage Company, Limited	(accepted)	1,350
Lithanode Electric Storage Syndicate, Limited		1,384
India-Rubber Gutta-Percha and Telegraph Works Company, Limited		1,587
Pritchetts & Gold		1,576
Chloride Electrical Storage Syndicate, Limited		1,700
Epstein Electric Accumulator Company, Limited		1,808
Peto Radford, Limited		1,862
Henry F. Joel & Co., and Thos. Potter & Sons, United, Limited		1,868
Allan & Adamson, Limited		1,943
Hill, Gilkins & Co.		2,036
Tudor Accumulator Company, Limited		2,043
D.P. Battery Company, Limited		2,119
J. C. Howell, Limited		2,247
Elieson Lamina Accumulator Company, Limited		2,508

SECTION F.—*Mains.*

Callender's Cable and Construction Company, Limited, approx.	(accepted)	£18,500
British Insulated Wire Company, Limited		

Schedule prices were quoted by the following:—Western Electric Company (Fowler-Waring Cables Company, Limited), W. T. Glover & Co., W. T. Henley's Telegraph Works Company, Limited, India-Rubber, Gutta-Percha and Telegraph Works Company, Limited, Siemens Bros. & Co., Limited.

SECTION G.—*Public Lamps.*

The decision upon the tenders for this section has been deferred.

Name of Firm.	Amount of Tender.
Stewart Electrical Syndicate (Part I. only)	£ 828
Brockie-Pell Arc Lamp, Limited (Part I. only)	1,058
Phæton Electrical Company, Limited	1,558
Taylor & Fairbrother	2,138
General Electric Company, Limited	2,206
Crompton & Co., Limited	[illegible]
Hill, Gilkins & Co.	2,387
W. Lucy & Co., Limited	2,488
British Insulated Wire Company, Limited	2,550
Brush Electrical Engineering Company, Limited	2,679
Siemens Bros. & Co., Limited	2,702
India-Rubber, Gutta-Percha, and Telegraph Works Company, Limited	2,717
British Blahnik Arc Light Company, Limited	2,859
Johnson & Phillips	3,144
Electric Construction Company, Limited	3,330
Drake & Gorham	3,681

SECTION H.—*Meters.*

Name of Firm.	Type of Meter.		Amount of Tender.
Chamberlain & Hookham	Hookham	(accepted)	£1,121
S. Z. de Ferranti, Limited	Ferranti		1,207
India-Rubber, Gutta-Percha, and Telegraph Works Company, Limited	Hookham		1,207
General Electric Company, Limited	British Aron		1,210
James White	Kelvin		1,210
Downie & Adams	Brillie		1,439

L.C.C.—The L.C.C. has, on the recommendation of the Fire Brigade Committee, accepted the tender of the National Electric Free Wiring Company (£992) to instal the electric light at the central station, Southwark Bridge Road.

Portsmouth.—For the extension of the station in Gunwharf Road (new boiler house, chimney stack, &c.), the Electric Light Committee has accepted the tender of Mr. T. W. Quick at £4,198. The following were the only tenders received for the boilers, steam pipes, condensers, economisers, &c.:—

	£	s.	d.
Messrs. Yates & Thom	7,900	0	0
Tinkers, Limited	9,215	0	0

The lowest tender was accepted. The engineer's estimate was £8,500.

FORTHCOMING EVENTS.

1898.

Friday, March 4th, 8 p.m.—At the Westminster Palace Hotel. The Institution of Junior Engineers. Paper on "An Outline of Patent Law and Practice," by Mr. Arthur H. Stanley, Fel.C.I.P.A., Member.

At 9 p.m.—Royal Institution, Albemarle Street, W. Prof. T. E. Thorpe on "Some Recent Results of Physico-Chemical Enquiry."

Saturday, March 5th.—Latest date for Northwich and Pembroke tenders.

Tuesday, March 8th.—Latest date for Belfast, Coventry, Liverpool, Shoreditch, and West Ham tenders.

Wednesday, March 9th, at 8 p.m.—Society of Arts. Prof. J. A. Ewing on "Linde's Method of Producing Extreme Cold and Liquefying Air." Prof. Dewar will preside.

At 8 p.m.—Mr. Mervyn O'Gorman will lecture on "Trades Unions and Factory Management" to the Brixton Literary Society, in the Lecture Hall of the Independent Church, Brixton.

At 7.30 p.m.—The Institution of Junior Engineers. Joint meeting with Architectural Association at 9, Conduit Street, W. Paper on "Desirability of a Closer Relationship between Architect and the Engineer," by Sydney B. Beale, A.R.I.B.A., and Percy J. Waldroun, P.A.S.I.

Thursday, March 10th, at 8 p.m.—The Institution of Electrical Engineers. Continuation of discussion on Mr. G. Binswanger-Byng's paper on:—"On the Manufacture of Lamps and other Apparatus for 200 Volt Circuits."

Friday, March 11th, at 5 p.m.—Physical Society at the rooms of the Chemical Society, Burlington House. Agenda:—(1) "On Dynamical Illustrations of certain Optical Phenomena," by Prof. J. D. Everett, F.R.S.; (2) "On Properties of Liquid Mixtures," by R. A. Lehfeldt.

Saturday, March 12th, at 7.30 p.m.—At the Westminster Palace Hotel. *Conversazione* of the Institution of Junior Engineers.

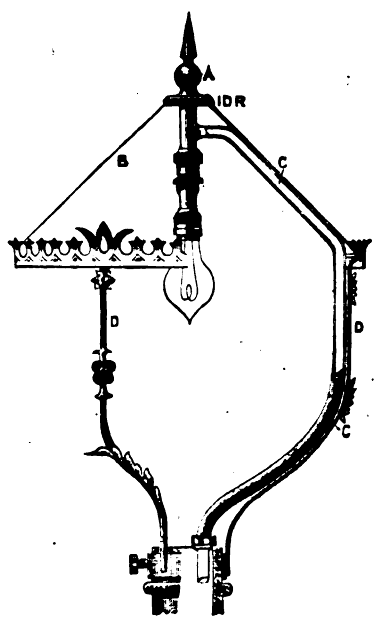
At 10.30 a.m.—Institution of Electrical Engineers. Students' visit to the stations of the Metropolitan Electric Supply Company. Applications to join the party should be made at once to the Students' Hon. Sec. (Mr. S. Grant, 28, St. Mary Abbot's Terrace, W.).

NOTES.

Electrical Engineers' Salaries—England v. America.—Some of our American contemporaries have been drawing attention to the low salaries paid to electrical engineers, scientific demonstrators, and other professional men in this country. The *Electrical World* in some editorial notes on the subject remarks that there is considerable difference of opinion as to the market value of intelligent effort, and in some quarters a disposition to believe it very small. A recent vacancy advertised by a London local authority is taken as a text. £130 per annum was offered for a chief electrical assistant, who had had a thorough electrical and mechanical training, and who was familiar with high tension alternating work. The gentleman appointed was to devote his whole time to the duties of his office. The *Electrical World* passes some severe strictures upon us, strictures which, in the light of recent events, appear to be, in a degree, justified. Our contemporary has, doubtless, overlooked the various appointments which have been made by some English municipalities recently at salaries much smaller than £130 per annum. The recent advertisement published for a "shift engineer" for high tension works at £50 a year (less than £1 a week), to which several correspondents have referred in our columns, we cannot seriously consider to be a true index of the general tendency among electricity committees. If it were so we should not like to prophesy regarding the operation of the plants. We do not know what our trans-Atlantic friends will think of the £50 instance. This is what they say of the £130 appointment:—

If this case is a fair index of the value of engineering service in England, it is no great matter for wonder that that country is so far behind in electrical progress. Nor is it remarkable that contracts come from there to this country, where there is a more proper recognition of the value of engineering service. A state of things that offers little better than labourer's wages to trained and skilled engineers cannot be productive of a high degree of ability among members of the profession, nor does it offer much incentive to young men to undertake the laborious course of preparation necessary to fit themselves for its exercise. Even in this country, where electrical engineering is notoriously overcrowded, such a rate of wage for such service would be regarded as ridiculous. It seems that, in England, the rates of payment for engineers are not much more than those for high-class mechanics. There a competent mechanic earns $10 a week; here he earns $21. Yet, notwithstanding this great difference, and a further difference against us in the cost of most of the raw materials of manufacture, we can under-sell English makers of electrical machinery in their own market. Perhaps the disregard of the money value of brains shown by the Council of the County Borough of West Ham, or the fact that engineers are so cheap thereabouts, may account for this otherwise anomalous fact.

Street Lighting by Glow Lamps.—The desirability of street lighting with incandescent electric lamps has been a matter of great consideration with the Derby Electric Lighting Committee. To meet this, the borough electrical engineer, Mr. J. E. Stewart, has designed a lantern, shown in the drawing annexed, which so adapts itself to the requirements that it has been decided to replace, in some of the main roads, the existing gas lamps with Mr. Stewart's lantern. As will be seen by the illustration, the lantern can be fitted on already existing gas lamp posts by means of an iron band and set



bolts. The lantern is fitted with a large opal shade, B, which is held in position by means of an ornamental cap, A, which is also provided with an India-rubber ring for weathering purposes. The copper pipe, C, carries the wires, and also forms the main support for the lamp connections, which are so constructed as to enable one or more lamps being fitted. The uprights, D, are of steel, and are riveted to a circumferential T-ring, to which is attached the ornamental copper spinning. The Corporation have approved the design, and will shortly erect some of the lanterns in the main thoroughfares of Derby.

India-Rubber Cables.—With regard to the alarmist reports from Dublin and Burton-upon-Trent, we regret that we have only received one reply from users of cables insulated with this material, although as we stated we should have been glad to have treated any answers we might receive as confidential. Nor have we yet heard from Prof. Kennedy or Mr. F. Bailey as to whether or not it is correct that in each case the cables were condemned without full test or complete examination. Prof. Kennedy based his report presumably to a large extent on the information supplied by the superintendent. Mr. F. Bailey is reported to have condemned the cables at Burton apparently without seeing them, but can this be so? Surely it is of interest to all central station engineers to get reliable information on the subject of cables at the earliest moment. Is not some forthcoming?

Personal.—Mr. Walter P. Adams, A.I.E.E., late of Messrs. Crompton & Co., has taken offices at 35, Queen Victoria Street, where he intends to practice as a consulting engineer, design and superintend electric lighting, power and heating installations, and periodically inspect and report upon any work which may be entrusted to his care. Mr. Adams has had a long and varied experience in electrical work of nearly every kind, five years of his career being passed in assisting Mr. Chamen, the newly appointed Glasgow engineer, and he is an expert in electric heating matters, having managed this department for Messrs. Crompton and Co. He has our best wishes for his success in his new venture.

Mr. F. Kenyon has been appointed resident engineer to the Northwich Electric Supply Company, in place of Mr. T. H. M. Swinburne, resigned.

Another New Storage Battery.—We have received a copy of a statement made by the inventor of a new storage battery, Mr. W. A. Crowdus, giving results of tests showing that at a discharge rate of about 1 ampere per pound of battery, it has a capacity of 18 watt-hours per pound of battery on a run of 9·5 hours' duration. If this result can be verified by an independent expert, it shows a considerable improvement. But the tests shown by the figures given are not what we should accept as quite correct. The rate of output in watts is allowed to fall during the test, as commencing with a rate of 16·8 watts, it gradually falls to 12·6 watts. Now, in practice we require quite as many watts from a battery on a car or a vehicle at the finish of a journey as at the beginning; hence, the tests, to be of practical value, should be made with a variable resistance in circuit, whereby the watts can be kept constant from the start to the finish. If this were done with the cell in question, the watt-hours per pound of battery would be much less than 18. We cannot keep the volts constant, but the amperes ought to be varied to keep the watts constant, if we are to obtain the true working capacity of a traction battery. To allow both amperes and volts to drop during a test gives a spurious result greatly in favour of any cell. A letter from an expert, Mr. Pumpelly, accompanying the inventor's statements says that a 14-lb. cell gives 15 amperes for six hours; this, calculated out, gives, approximately, 12 watt-hours per pound of cell. But, beyond all this, a letter from Mr. John T. Bowden, who holds the patent rights for Great Britain, demands more drastic treatment. He says:—A $3\frac{1}{2}$ horse-power motor is worked from 44 cells of 100 amperes (hours) capacity each. Now, in a report made by Mr. Pumpelly, the 14-lb. cell would just weigh $5\frac{1}{2}$ cwt. if made up on a battery of 44 cells. Pumpelly says this cell gives 100 ampere-hours or 15 amperes for six hours; further, 44 cells will not give more than 85 volts, and 85 volts multiplied by 15 amperes, equals 1,275 watts, or a little more than 1·5 horse-power. How is a $3\frac{1}{2}$ horse-power motor to be driven with a $1\frac{1}{2}$ horse-power battery? The letter informs us that the cell has been tested very carefully; this may be so, but it evidently has not been carefully *reported* upon! If Mr. John T. Bowden believes in reports which appear to be based upon so evidently erroneous figures, he is, we fear, doomed to considerable disappointment if he ever submits his cells to the tests of a competent expert. To get an available $3\frac{1}{2}$ horse-power out of 44 cells, we must obtain a 35-amperes discharge, and at this rate the cells would be exhausted in about two hours, so that it must do the alleged 50 miles at 25 miles an hour. Although things go pretty "slick" in Chicago, their wagons do not seem to fly at this rate. In fact, the figures appear both contradictory and improbable.

Appointment.—Mr. T. U. N. Aldridge has been appointed by the Crown Agents for the Colonies as electrical engineer to the Public Works Department, Lagos, West Africa, for a period of six months.

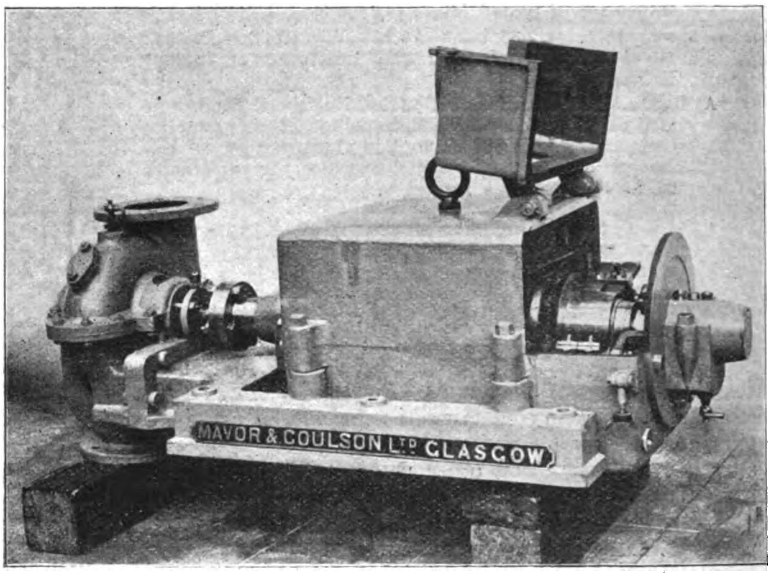
The City Company's Charges.—It is stated that the City of London Electric Lighting Company is reducing its scale of charges, and from the commencement of 1898 the charge for lighting will be 7d. per unit for the first six consumed per 8-C.P. lamp, 6d. for the next four units, 5d. for the next two, and 4d. per unit after. For motive power purposes, the charge will be 3d. per unit for a minimum of 45 hours per week, and 4d. otherwise.

Obituary.—By the last advices from Cape Town we have information of the death, at the early age of 37, of Mr. J. K. Waterman, manager of the Cape Electric Tramways.

We regret to learn of the death of Mr. Thomas Holliday, of the firm of Read Holliday & Sons, Limited, manufacturing chemists and electricians, which occurred on the 1st inst. Mr. Holliday was 57 years of age.

Lord Kelvin's Patents.—Before the Philosophical Society at Glasgow on 23rd ult., Dr. Magnus Maclean, read a paper on "Lord Kelvin's Patents." There were, he said, altogether 47 patents from February 20th, 1858, to September 28th, 1896—a period of 38 years. All of them could be conveniently classified under four heads:—A. Patents relating to improvements in electric telegraphic apparatus. B. Patents relating to improvements in navigational apparatus. C. Patents relating to improvements in generating, regulating, measuring, recording, and integrating electric currents. D. Improvements in valves for fluids. Under the first head (A) there are 11 patents. Under the second head (B) there are 10 patents. Under the third head (C) there are 24 patents. Under the fourth head (D) there are two patents. There are up to September 28th, 1896, 47 patents.

Motor-driven Pump.—We illustrate below a motor-driven centrifugal pump for condensing plant. The pump, which was made by Messrs. Mavor & Coulson, is designed



to raise 640 gallons of water per minute against a head of 28 feet. The motor develops 10 brake H.P. at a speed of about 900 revolutions per minute.

Electrical Engineers Royal Engineers Volunteers.—The head-quarters of the corps at 13, Victoria Street, Westminster, are now open during the week, Saturdays excepted, from 11 to 4, between which hours general information in reference to the corps can be given to inquirers. On Monday and Thursday evenings, at 8 p.m., some of the officers are in attendance for the purpose of considering applications and enrolling recruits.

The Diesel Rational Heat Motor.—The Diesel heat motor, of which we have already given a description, appears to be securing a considerable amount of attention, not only here, but in America. The new motor is essentially novel in its principles and decidedly worth study, for it is very different from other motors. Its initial pressure is secured by mechanical compression of air up to the point of ignition of the fuel, and the fall of temperature due to expansion is made up by the continued combustion of added fuel up to the "cut-off" point, after which expansion proceeds in the usual way. So far, petroleum has been the fuel managed successfully, but powdered coal is hoped to be used. Initial pressures of 500 to 600 lbs. have to be dealt with, but the Diesel motor is not large for its power, and is expected to cope with these pressures; but undoubtedly high pressures will for some time yet prove a little difficult to manage. As the tests of Schröter and Gutermuth and others have shown an efficiency of 34 to 35 per cent. for full load, and even 38 to 40 per cent. for half loads, there is very good reason to endeavour to deal with the high pressures. The best gas engine efficiency recorded is, we believe, only 27 per cent. by Dugald Clerk. The increased efficiency at less than full load is a remarkable feature. Altogether, the new motor is likely to receive considerable application in the near future.

Lecture.—On Tuesday last week Mr. H. Kilgour, borough electrical engineer, Cheltenham, lectured at the Gloucester Guildhall, his subject being "Notes on Electric Lighting and Electric Works."

NEW COMPANY REGISTERED.

Electric Installation Company, Limited (56,171).—Registered February 19th with capital £100,000 in £1 shares, to carry on the business of an electric light, telephone and telegraph company in all its branches, and to construct, lay down, establish, fix and carry out all necessary cables, lines, accumulators, lamps and works. The subscribers (with one share each) are:—W. Coffey, 50, High Street, Manchester, manufacturer; J. Boydell, Cowley Hill, St. Helens, merchant; T. Currie, 28, Swan Street, Manchester, factor; H. T. Johnson, Dakeim Lymm, Chester, engineer; R. A. Beaver, 3, Old Hall Street, Liverpool, merchant; R. V. Critchley, 6, St. James's Square, Manchester, chartered accountant; F. F. Bennett, 13, Victoria Buildings, Manchester, engineer. The number of directors is not to be less than five nor more than seven; the first are the first five subscribers; qualification, £250; remuneration as fixed by the company. Registered office, 6, St. James's Square, Manchester.

OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

Thomas G. Poole, Limited (53,736).—This company's statutory return was filed on February 12th. 507 shares have been taken out of a capital of £3,000 in £1 shares, and all are considered as fully paid.

Amazon Telegraph Company, Limited (44,532).—This company's return was filed on January 20th. The capital of £250,000 in £10 shares has been fully subscribed, and paid for in full.

London Electrical Omnibus Company, Limited (47,990).—This company's return was filed on January 21st. The capital of £250,000 in £1 shares, (80,000 deferred). All the deferred and 17,818 ordinary have been taken up, and the deferred are considered as paid. 19s. 6d. per share has been called on the ordinary, and £33,274 2s. 6d. has been paid (including £17 15s. paid in advance). £15,500 9s. is in arrears, and £16,520 8s. 6d. has been received on 32,189 forfeited shares.

CITY NOTES.

The Dover Electricity Supply Company, Limited.

The report to be presented at the fourth annual general meeting of shareholders of the Dover Electricity Supply Company, Limited, to be held at the offices, Park Street, Dover, on Wednesday, March 9th, 1898, at 3.30 o'clock, states that the capital expended during the year amounted to £11,932 7s. 9d., making the total to December 31st last £62,836 7s. 9d. Of the amount thus expended £7,915 0s. 3d. was for additional generating plant necessary for the supply of current to the cars of the Dover Corporation Tramways, the running of which commenced in September last, has given great satisfaction to all concerned, and it is not unlikely that the present service may be increased, additional cars having been lately ordered. In the early part of the year it was decided to issue £25,000 4½ per cent. debenture stock, and the whole was subscribed for at a considerable premium, of which the balance, amounting to £761 2s. 6d., after payment of all legal and other charges in connection with the issue, has been applied to reduction of the previous debits to revenue account.

The directors consider the result of the year's working very satisfactory, since, instead of a loss of £455 19s. 11d., as in the previous year, there has been a gross profit of £1,127 17s. 5d. on revenue account. The company may now be considered as fairly established on a profit-earning basis, and the directors believe that in future years the annual increments in gross profits will at least equal, if not exceed, those for the year just ended, as during the construction and after the completion of the national harbour at Dover the trade of the town will largely increase, to the benefit of all its present established undertakings.

During the year applications have been received for the equivalent of 2,748 8-C.P. lamps, including nine additional arc lamps for street lighting (of which there are now 40 in all), making the total applied for on December 31st last 10,376, and of these 10,137 were then connected to the company's mains.

With the view of inducing an increased average daily use of electricity by householders, your directors decided to adopt, as from July 1st last, the demand indicator system of charging, and to reduce the cost of current after the first two hours' daily consumption from 5d. to 3½d. per unit. This system has been introduced in Brighton and many other towns, where it has given general satisfaction; and your directors believe that as its advantages become more generally known, both consumers and the company will correspondingly benefit.

The retiring directors are Mr. C. W. Bagshawe and Mr. R. Percy Sellon, who, being eligible, offer themselves for re-election. The auditor, Mr. R. H. Marsh, chartered accountant, also retires, and is eligible for re-election.

The Richmond (Surrey) Electric Light and Power Company, Limited.

The report presented to the shareholders at the fourth ordinary general meeting of the company, held at the registered offices of the company, Moorgate Court, yesterday, states that the directors beg to submit their report and statement of accounts for the year ended December 31st, 1897. The capital expended during the year amounted to £3,828 17s. 1d., making the total expenditure at December 31st last £44,793 11s. 9d.

Of the amount expended during the period under review, the principal items are in respect of mains and accumulators, the latter of which have been increased to more than double their previous capacity. The balance to credit of revenue account, including the amount brought forward, and after payment of interest, depreciation and reduction of suspense account, is £1,072 18s., as against £33 14s. 9d. in 1896. Out of this sum the directors recommend the payment of a dividend on the ordinary shares of the company at the rate of 3 per cent. for the year ended December 31st, 1897, which will leave a balance of £133 to be carried forward to next account.

The total number of lamps connected on December 31st last was equivalent to 9,512 8-C.P., being an increase for the year of 2,387. In order to meet the growing demand for current, additional plant will be installed in time for next winter's lighting, and further extensions of mains have already been decided upon.

The retiring director is Mr. F. W. Reynolds, who, being eligible, offers himself for re-election. Mr. R. H. Marsh, the auditor, also retires, and is eligible for re-election.

Mr. Frederick W. Reynolds (chairman), presided at the meeting of the company, and in moving the adoption of the report, said he congratulated them at last on reaching a small dividend. The improvement shown in 1896, had been maintained during the year, which was very satisfactory considering the condition of affairs which prevailed in Richmond. The receipts from the sale of current, showed the satisfactory increase of £1,116 15s. 3d., and the total income for the year was £4,468 16s. 6d., as compared with £3,194 8s. 8d. in 1896. The working cost £2,235 11s. 2d., as compared with £2,031 10s. 10d., being only £204 0s. 6d. increase, while the current sold increased to 41,872 units. After payment of interest, and provision for depreciation, &c., they had £1,072 18s. left, out of which a dividend was recommended of 3 per cent. That was the first dividend, and he thought it augured well for the future of the company. The lamps connected on December 31st were equivalent to 39,512 8-candle-power lamps, an increase of 2,387 over last year. There were applications for a further 425 8-candle-power lamps, so that with those connected and those applied for, they had now 10,000 lamps. The total units sold was 138,916, against 97,044 in 1896. In view of the encouraging prospects, it was the intention of the board to lay down more plant for the winter lighting, and they also intended to extend the company's mains, which would go into some of the principal residential streets of Richmond.

The Chevalier Soares seconded the motion, and it was agreed to.

The Hove Electric Lighting Company, Limited.

The report of the directors to be presented at the annual general meeting of the shareholders at the City Terminus Hotel, Cannon Street, in the City of London, on Monday, March 7th, 1898, at 12 o'clock noon precisely, states that the progress and improvement in the position of the company continue satisfactory.

As stated in their report last year, the directors made a very considerable reduction, from January 1st, 1897, in the price of current, charging the consumers for the first hour 6d. per unit and for all current subsequently consumed 4d. per unit only. This reduction, which practically amounts to 20 per cent. in the charge for current, has had the effect anticipated of increasing the number of consumers and the consumption of electricity to such an extent that the large reduction is more than compensated for by the increased consumption.

The revenue from the sale of current has increased to £6,838 17s. 10d., and after debiting profit and loss account with the cost of generation and distribution of electricity, and management expenses, there remains a net profit for the year of £3,602 9s. 8d. compared with £3,114 5s. 6d. in 1896. To this amount must be added £183 7s. 10d. brought forward from last year, increasing the amount to be dealt with to £3,785 17s. 6d., and after deducting debenture interest paid and accrued and the interim dividend paid in October last, there remains a net balance of £2,092 7s. 11d. at the credit of the revenue account.

The directors propose to write the sum of £150 off preliminary expenses account, to place £600 to the reserve fund, to declare a dividend (payable on April 15th next) at the rate of 6 per cent. per annum for the half-year on the share capital (making, with the interim dividend, 5 per cent. for the year), and to carry the balance, £218 7s. 2d., forward. The number of lamps attached to the company's system has increased to the equivalent, at December 31st last, of 27,777 8-C.P. lamps, and the number or consumers to 397, compared to 21,756 lamps and 314 consumers at December 31st, 1896.

Out of the sum of £600 which has to be set aside for repairs and maintenance, in accordance with the contract with the Hove Commissioners, the unexpended sum of £390 13s. 11d. has been placed to the depreciation and maintenance reserve fund, bringing the total of this account to £914 10s., while the general reserve fund, by the addition now proposed to be made, will stand at £2,259 17s.

Since the date of the last report the directors have issued £2,400 of 4 per cent. debenture stock, bringing the total amount issued at the present date to £17,000.

The increase of the company's business, and the continued applications for supply of current from residents in new streets entail upon the company further outlay on mains and machinery, for which additional capital is required. The directors, therefore, propose to increase the capital of the company to £50,000 by the creation of 2,000 new shares of £5 each, ranking *pari passu* with the existing shares, and the necessary resolution for giving effect to this proposal is contained in the accompanying notice of meeting. The directors propose to make an early issue of 1,000 of these shares which will be offered to the whole of the members of the company, *pro rata*, at a premium.

A resolution will also be submitted for consideration, increasing the limit of the directors' borrowing powers from £25,000 to £50,000.

The County of London and Brush Provincial Electric Lighting Company, Limited.

The report to be presented to the shareholders at the fourth ordinary general meeting of the company to be held at Winchester House, Old Broad Street, London, E.C., at 12 o'clock noon, on Monday, March 14th, 1898, states that the capital expenditure during the year in respect of the company's London districts amounted to £141,066 3s. 9d. Of this sum £138,078 5s. 10d. has been expended at St. Luke's and Clerkenwell and at Wandsworth, making the total expenditure on the two London stations up to December 31st last, £410,801 12s. 1d.

This expenditure was met by the balance of instalments falling due on the second issue of 10,000 6 per cent. preference shares, and by the sale at a premium of the balance of the second issue of ordinary shares. In order to provide funds for additional requirements during the current year, a further 10,000 ordinary shares at par were allotted *pro rata* to the ordinary shareholders on December 6th last.

The premium received on the balance of the second issue of ordinary shares has been applied as follows:—

	£	s.	d.
To reduction of general preliminary expenses	3,253	19	6
To writing off costs in connection with applications for provisional orders	889	15	6
Amount carried to reserve (raising this item to £5,000)	1,500	0	0

The interests of the company in the Bournemouth and District Electric Supply Company, Limited, have been disposed of to the Bournemouth and Poole Electricity Supply Company, Limited, at a substantial profit. Your directors deeming it to your advantage to retain an interest in the latter company, applied for and received an allotment of ordinary shares at par.

The net revenue for the year, including the balance from last account, and after payment of proportion of rents, rates, taxes, interest, and general establishment charges, is £21,400 14s. 2d. Out of this sum an interim dividend on the preference shares for the half-year ended June 30th last, at the rate of 6 per cent. per annum has been paid; and the directors now recommend that a further dividend on the preference capital for the half-year just ended be declared at the same rate. This will leave a balance of £10,090 14s. 2d., which it is proposed to carry forward.

The company's two London generating stations are now fully equipped and in good running order, having a joint plant capacity sufficient for the supply of 120,000 8-C.P. lamps connected. It is intended to supply the company's districts north of the Thames from the St. Luke's station in City Road, and those on the south side of the river from the station on the Wandle.

For the information of shareholders a map is attached to the report, showing:—(*a*) Districts where current is now being supplied. (*b*) Districts wherein works are in progress. (*c*) Districts for which provisional orders have been obtained (works not yet commenced). (*d*) Districts where the consents of the local authorities have been obtained to the company's application for provisional orders.

The retiring directors are Mr. B. H. Van Tromp and Mr. R. Percy Sellon, who are eligible for re-election.

LONDON STATIONS.

St. Luke's and Clerkenwell.—The station buildings and the equipment thereof are practically completed. The plant installed is capable of supplying 80,000 8-C.P. lamps connected. The equivalent of 23,757 8-C.P. lamps were connected to the mains at December 31st last, showing an increase of 9,578 for the year; and applications representing a further 1,073 were then awaiting connection. A considerable demand having arisen for motive power, separate mains have been laid down, and a supply of current for power purposes is now available in most of the important thoroughfares in the district.

Holborn (Eastern Portion).—A provisional order for the eastern portion of this district was granted to the company by the Board of Trade, and confirmed in the last session of Parliament. The work of laying mains in the compulsory area was at once taken in hand, and current is now being supplied to consumers within this district from the generating station in City Road. The company's application to the Board of Trade for a provisional order for the western portion of Holborn, and for the adjoining district of St. Giles-in-the-Fields, has received the consent of the local authorities.

Wandsworth.—The station buildings on the Wandle were completed during the year, and the capacity of the plant there installed is equal to 40,000 8-C.P. lamps connected. The company's mains have been carried into new neighbourhoods, and further extensions are in progress. The supply of current was commenced in the early part of 1897, and since September last has been available throughout the 24 hours. The equivalent of 13,907 8-C.P. lamps were connected to the mains at December 31st last, showing an increase of 13,690 for the year, and applications representing a further 2,927 were then awaiting connection.

Camberwell.—The work of laying mains in the compulsory streets within this district has been commenced, and it is expected that by next autumn a supply of current will be available.

Mile End Old Town, St. George's-in-the-East, and the district of the Limehouse District Board of Works.—Provisional orders for these districts were granted by the Board of Trade in 1896, and confirmed by Parliament in 1897.

PROVINCIAL STATIONS.

The Dover Electricity Supply Company, Limited.—In the past year an important addition was made to the Dover Station by the laying down of generating plant for the supply of current to the Corporation tramways. The running of the trams by electricity was commenced in September last. In the second completed year of the working of this station the gross profits amounted to £1,127 17s. 5d., as against a loss in 1896, and the company may now be considered as fairly established on a profit-earning basis. The equivalent of 10,137 8-C.P. lamps were connected to the mains at December 31st last, showing an increase of 2,619 for the year (including nine arc lamps for street lighting); and applications representing a further 239 were then awaiting connection. In the early part of 1897 the Dover Company made an issue of £25,000 4½ per cent. debenture stock, the interest upon which is guaranteed by the company.

The Richmond (Surrey) Electric Light and Power Company, Limited.—A considerable improvement is shown in this company's accounts for the year under review. The gross profits amounted to £2,233 5s. 4d., which allows of a dividend of 3 per cent. on the share capital, after providing for interest charges and reserve for depreciation of plant, &c. The equivalent of 9,512 8-C.P. lamps were connected to the mains at December 31st last, showing an increase of 2,387 during the year; and applications representing a further 220 were then awaiting connection. In order to meet the increasing demand for current at this station, it is intended to lay down additional plant during the present year, and further extensions of mains have been decided upon.

Isle of Man Tramways Company.

The report of the directors for the year ended December 31st last, to be submitted at the general meeting to be held on the 10th prox., states that the balance of profit and loss account, after providing £6,500 for debenture interest, is £11,154. The directors propose dividends at the rate of 6 per cent. on the preference, and 7 per cent. on the ordinary shares, absorbing £10,850, of which £5,669 has been paid in interim dividends, and that the balance of £304 be carried forward. The loss on the first half-year's working of the cable section has been exceptionally heavy, owing to many unforeseen circumstances and through frequent stoppages. With the experience gained, the management confidently hope next year to have a satisfactory return on the cable lines. It is expected that the new electric tramway from Laxey to Ramsey, now in course of construction, and which will be worked as a separate undertaking, will be opened for next summer's traffic, and will bring considerable increase of revenue on the company's present lines.

Telegraph Construction and Maintenance Company, Limited.

Sir Anthony H. Hoskins, who presided at the ordinary meeting of this company, held on Tuesday, regretted the absence of the chairman, Sir Robert Herbert, through illness. They had had no important contract to carry out during the period under review, but their factories at Wharf Road and East Greenwich had been actively employed, and they were able to maintain the dividend at the same rate, 15 per cent., as last year. They carried forward a somewhat smaller amount, but they consider it better to do that, rather than to lower the dividend. They would be interested to learn that this was the 50th year of the most important branch of the manufacture—the insulation of telegraph wires. Their gutta-percha works were started in 1845, although it was not till 1848 that the insulating properties of gutta-percha were generally recognised. The total amount of raw gutta imported into this country had been officially stated to be 84,000 tons, of which he believed 40,000 had been used by their company. The gutta-percha manufactured by them had been mostly for submarine cables, of which they had made 145,000 knots of various sized cores. Gutta remained to-day unrivalled as an insulator for submarine cable cores. It was interesting to note that they were manufacturing for the British Postal Telegraphs a telegraph cable, 60 knots in length, to be laid between this country and Ireland, having a core of novel design. It possessed considerable electrical advantages, and they hoped the form would solve the question of telephonic communication. The cable had been invented by their engineer, Mr. Willoughby Smith, and his assistant, Mr. Granville, and a small section had been laid in Southampton Water, and had been successful. They had entered into a contract for building a new cable steamer, which would be the largest telegraph ship in the world. In planning and designing her they had had the accumulated experience extending over a good many years, and they could reasonably expect the vessel to be thoroughly up to date. It was absolutely necessary that a vessel of her capacity and dimensions should be brought into use with a view to securing contracts that may be forthcoming in the future. She would be capable of lifting a dead weight of 8,000 tons, and that would enable her to carry the largest ocean cable in one length. It would be fitted with twin screws, the engines and boilers would be of a modern type, and would give a speed of 12 knots per hour on a moderate consumption of coal.

After one or two remarks from shareholders, one of whom elicited from the chairman the fact that the new cable ship would be finished in early autumn, the report was adopted.

The statutory provision for depreciation and reserve funds in accordance with the City of London Electric Lighting Act, 1893, has been made, of which £20,528 have been set aside out of revenue. The generation and distribution expenses for the year, including repairs and renewals, were 31·3 per cent. of the earnings, as compared with 34 per cent. in 1896, 36 87 for 1895, 46 for 1894, and 54 2 for 1893.

The progress made by the company will be seen by the following comparative statements, which show the position as it was in 1892 and at subsequent periods:—

NUMBER OF CUSTOMERS AND LAMPS CONNECTED.

	Dec. 31st, 1892.	Dec. 31st, 1893.	Dec. 31st, 1894.	Dec. 31st, 1895.	Dec. 31st, 1896.	Dec. 31st, 1897.
Number of customers being supplied	242	1,080	2,740	4,280	5,808	6 322
Number (equivalent) of 8-C.P. lamps connected	20,241	65,341	135,460	195,817	247,785	296,012

On February 9th, 1898, there were 316,705 8-C.P. lamps (equivalent) applied for, out of which 302,871 were connected.

STATEMENT OF INCOME AS SHOWN IN THE AUDITED STATEMENTS OF ACCOUNTS ISSUED BY THE COMPANY.

	For the period to Dec. 31st, 1892.	For the year ended Dec. 31st, 1893.	For the year ended Dec. 31st, 1894.	For the year ended Dec. 31st, 1895.	For the year ended Dec. 31st, 1896.	For the year ended Dec. 31st, 1897.
	£ s. d	£ s. d.	£ s. d.	£ s. d.	£ s. d.	£ s. d.
Gross revenue (after deducting allowances to consumers)	12,450 5 4	39,662 17 9	68,863 19 3	106,999 17 2	146,946 14 7	175,792 13 2

The City of London Electric Lighting Company, Limited.

THE report presented to the shareholders at the ordinary general meeting held on Wednesday stated that the expenditure on capital account during the year ended December 31st, 1897, amounted to £82,085 17s. Details of this outlay are given in the capital account No. III.

REVENUE.

				£	s.	d.
The total revenue for the year was				190,573	12	11
From which must be deducted the following items:—						
Expenses of generation and distribution	£42,923	10	8			
Rents, rates, taxes, general charges	23,980	19	6			
Allowances to consumers	14,780	19	9			
Transfer to depreciation fund No. 1	17,000	0	0			
Transfer to reserve fund	3,528	0	0			
Amount written off suspense account	1,338	0	8			
				103,551	10	7
Leaving				87,022	2	4
To which must be added the balance brought forward from 1896				1,415	3	1
Making a total available revenue of ...				88,437	5	5
Of this sum the following amounts have been distributed:—						
(a) Interest on debenture stock for year ended December 31st, 1897	£20,000	0	0			
(b) Interim dividend on £400,000 6 per cent. preference shares, half-year to June 30th last ...	12,000	0	0			
				32,000	0	0
Leaving for further distribution				£56,437	5	5

The directors now recommend the payment of the following dividends, subject to the deduction of income-tax, to members registered in the books of the company on February 16th, 1898.

Preference Shares.—6s. per share for the six months ended December 31st, 1897, making, with the interim dividend already paid, a total distribution of 12s. per share, or at the full rate of 6 per cent. per annum.

Ordinary Shares, Nos. 40,001 to 80,000.—£1 per share for the 12 months ended December 31st, 1897, being at the rate of 10 per cent. per annum.

Ordinary Shares, Nos. 80,001 to 90,000 (February, 1897, issue).—10s. 7d. per share, being at the rate of 10 per cent. per annum, calculated from the due dates of the respective instalments to December 31st, 1897.

This will absorb £55,381 18s. 10d., and leave a balance of £1,055 6s. 7d. to be carried forward. It is proposed that the respective dividends shall be paid on March 3rd, 1898.

The ordinary general meeting of the shareholders of the above company was held on Wednesday at Winchester House, Old Broad Street, Sir David L. Salomons presiding.

The CHAIRMAN, in proposing the adoption of the report, said it was satisfactory that the directors were able to recommend a dividend at the rate of 10 per cent. per annum. To effect that, it had been necessary to take £5,000 from the premium fund towards depreciation, and approximately a similar sum was taken last year for the same purpose. In 1896 the revenue was aided, from the fact that there was a sum somewhat exceeding £5,000 from the profits on investments; also the sum that was put to the depreciation fund, making in all £10,000 added to the revenue. In other words, last year they paid 7 per cent. dividend with the aid of that additional £10,000; but this year they would be able to pay 10 per cent.—with the approval of the shareholders—without having had the advantage of that additional £10,000. Those facts showed that the business was progressive. It also proved that which he had often referred to, that when the business had reached a certain point, they would be able to make much larger profits at a very small additional cost. As they could well understand, the standing charges remained virtually the same, it was simply a question of burning a little more coal, and keeping the machinery running for a longer period to produce a larger output of current. In 1896 about £10,000 was taken from the premium fund to assist the depreciation fund number two, and this year it was proposed to take £20,000 to add to that fund, as they considered that that fund being a voluntary one on the part of the board, should be kept up to a fair amount to meet any contingencies that might arise in the future. The expenditure on capital account during the year had amounted to £82,085. It might be curious to notice that their freehold investments appeared to be less than they were the year before, but that was really to be accounted for by the fact that some of the investments had been shifted from a general heading, and put definitely to represent the depreciation and reserve fund. The capital expenditure had increased, and also the expenditure for running the company during the year, which was due to their having supplied a greater amount of current. It was very satisfactory to know that the demand for the supply of electric energy continued to increase. The number of customers on February 23rd was 6,517, the number of lamps applied for was 318,741, and the number of lamps connected to the circuits 305,163. That afforded abundant proof that not only was the electric light appreciated in the City, but also that they had given satisfaction to their customers. The great fire in Cripplegate at one time gave the directors very great anxiety, but he was very glad to be able to say that the damage caused to the company was only nominal—between £200 and £300 would cover their entire loss. It was said it was an ill wind that blew nobody any good, and it was possible that, as a result of that fire, their company might benefit, for they were sending round a circular to the builders of the new premises that were to be erected, pointing out the advantages that would accrue by wiring the premises for the electric light. He had had a letter from a shareholder who had asked whether the board could not see their way to paying an interim dividend in the future. To that he would say that, if the business continued to prosper in the coming years as it had done in the past, the directors saw no objection to that course, seeing that it would meet the wishes of many shareholders. He would like to point out, however, that any interim dividend would necessarily be small, as the first half of the year was always a small one. Referring to the relations of the company with the City authorities, the chairman said that the directors were anxious to meet the Corporation in all matters in a fair and even conciliatory spirit. They were a business company carrying on operations for the purpose of obtaining a profit on their investment, and therefore had no desire to enter into litigation, and they would only have recourse to the law courts to enforce their just rights. If such a position were forced upon them the board would protect the rights of the shareholders; but, as he had said, they desired to act in harmony with the authorities. It had been decided to reduce the maximum price from 8d. to 7d. per unit, and the board hoped to reduce the price still further as the exigencies of the business admitted of it. In order to give the public the fullest possible benefit, they had decided to make that reduction date back from January 1st last.

The report was adopted.

The retiring directors—Mr. Edward Lucas and Mr. F. W. Reynolds—having been re-elected, a similar proposition was agreed to with reference to the auditors, Messrs. W. H. Pannell & Co.

A vote of thanks to the Chairman for presiding closed the proceedings.

Notting Hill Electric Lighting Company.

The annual general meeting of this company was held at Winchester House, on Wednesday, Sir William Crookes presiding.

Referring to share capital account, the Chairman said the whole £100,000 of share capital had been issued and paid up. In the loan capital there was still £40,000 of 4 per cent. debentures available for issue against further capital expenditure. By making use of these the shareholders reap the benefit, as the debentures carried interest at 4 per cent. only, whereas a further issue of shares would rank for dividend with the old ones, and would therefore have to receive the full 6 per cent. By issuing debentures, however, the odd 2 per cent. goes to increase the share dividends. During the year the directors allotted £10,000 of the 4 per cent. first mortgage debentures at £106 per cent., being part of an issue of £50,000 secured on the company's undertaking by a trust deed. They anticipated requiring about £11,000 this year, and the issue price of the debentures will be increased to £107 10s. per cent. The amount of capital expended on lands, buildings, mains, and machinery, was £3,184 in excess of the amount received from shares and debentures. Very little capital was expended during the year except on new mains, which represent £11,769 of the total expenditure of £14,079. The reason for this large expenditure is that they had now seriously commenced to lay mains in the principal streets of the new area, most of the compulsory ones being already supplied with current. They had every reason to be satisfied with the number of customers on the new extensions, which appeared an almost certain source of additional revenue; but there was still a large field for further development. Other small extensions of the mains had to be made in the old area, and they were always prepared to extend into any street where the demand appeared sufficient to guard against a loss being incurred on the capital employed. The revenue account was in a very satisfactory state, the number of units sold having increased during the past 12 months from 230,787 to 354,969, or 50 per cent., and the total revenue from £8,550 to £11,620. The increase in the revenue, compared with the previous year, is over £3,000, but the expenses show an increase of only about £900. The principal increases were for coal, repairs, and rates. The whole of the machinery and mains are kept in an efficient state of repair, the entire cost being taken out of revenue. He took the opportunity of expressing their entire satisfaction at the excellent manner in which their engineering staff, under Mr. Schultz, had carried out the duties devolving on them, more especially in view of the very anxious times at the end of the year. Owing to the labour troubles at that time in the engineering trade, the contractors were unable to deliver the large engine and dynamo which should have been completed last summer ready for the winter load. Had one of the machines failed at the critical moment, they would have been in a most awkward predicament, having no spare plant whatever to fall back upon. Happily, no accident occurred, and the new machinery was delivered last week.

A table was then given showing the progress of the company. Their revenue per 8-C.P. lamp still continued low, being about 6s. only, showing that their district was not so good as most of the others in London, where the average consumption per lamp was above 10s. They hoped to derive considerable benefit from their contract with the National Electric Free Wiring Company, who undertake to wire houses and provide suitable fittings free of initial cost to the consumer, who merely had to pay an additional 1d. per unit, which 1d. is handed over to the Free Wiring Company. Already 20 houses had been connected on those terms. They had every reason to be satisfied with the result of the reduction in the price per unit to 6d. at 200 volts; and although their principal thought must be to benefit shareholders, they must not overlook the claims of those who supply the dividends, viz., the consumers. As many of their shareholders were also using their light, he could assure them that their interests would be very carefully considered, and immediately it was possible to make a further reduction they could rely that this would be done. The dividend of 6 per cent. on the ordinary shares, which they now recommended, marked a period in their history. After this was paid, preference and ordinary shares ranked equally for dividend, and the founders' shares came in for their proportion. To simplify matters, they proposed to regard the ordinary dividend as a 6 per cent. one, payable half yearly, and at the end of the second half year proposed to pay in addition such bonus as the profits may allow. The total amount of profits available for dividend, after payment of the 6 per cent., would be divided into two moieties, and one moiety would go to the 9,450 preference and ordinary shares *pro rata*, and the other moiety to the 550 founders' shares *pro rata*.

After some little discussion the report was adopted.

Henley's Telegraph Company, Limited.

Mr. Sydney Gedge, M.P., presided at a general meeting of this company, which was held last Friday at the offices of the company, Martin's Lane, E.C., and referred to the fact that the company for some years had been going on well, and improving in every way its position and its prospects. He congratulated the shareholders upon the success which had attended the efforts of those who had the management in their hands. Dwelling for a moment upon the progress that had been made during the five years, the chairman said in 1893 they issued £30,000 preference shares partly to pay off debts, and partly to provide fresh capital. The benefit of that was felt during the following year, for they made a very substantial profit of £10,771, and were able to pay a dividend of 5 per cent. They also raised fresh debentures at a lower rate of interest, to replace older ones, and they practically increased their capital by £12,000 at an increase of interest of only £253. They commenced to pay better dividends, and in 1895, when they wanted more capital, they increased from the nominal £70,000 to £100,000, the whole of which issue was taken up at par by their own shareholders and friends. It was found necessary in 1896 and last year to further increase the capital, and they issued £25,000 of further capital at a very considerable premium, making, in fact, £15,000, which had been added to the reserve fund. Their business was increasing so rapidly, and as they found it necessary to have the best of machinery, it was not at all unlikely, before the year ended, that they would have to issue another £25,000, although shareholders must not expect to get them at the same price as the last. The profits for the last five years had been as follows:—

	Profits.	Paid in dividends.
1893	£10,780	£6,000
1894	16,450	6,800
1895	21,820	9,500
	(£1,600 from previous year)	
1896	26,080	12,400
	(less £500 to directors)	
1897	29,585	15,800

Their net profits had continuously progressed, and the sums paid in dividends had also increased year by year, and at the same time they had been able to pay dividends out of profits actually earned. The actual earnings had paid interest on debentures, and during the five years they had written off £10,000 for depreciation, added £20,000 to the reserve fund, besides the £15,000 profit on issuing shares, they had paid in dividends £50,500, carrying forward £12,700 to 1898. Referring to the present accounts, they would see that the value of stock had increased, but it was not unsaleable stock, but represented goods which they might have to supply at 24 hours' notice. Referring to the effects of the strike, the chairman said that in their case men of inferior position had been put to do the work of the skilled workmen, and the result had been that they had done more and better work.

After some remarks from shareholders the accounts were adopted.

Stock Exchange Notices.—The Stock Exchange Committee has appointed Thursday, March 10th, a special settling day as under:—Chelsea Electricity Supply Company, Limited—Further issue of 8,000 ordinary shares of £5 each, fully paid, Nos 32,501 to 40,500; and National Electric Free Wiring Company, Limited—100,000 shares of £1 each, 5s. paid, Nos. 1 to 100,000. The Committee has also ordered the under-mentioned securities to be quoted in the official list:—Edmundson's Electricity Corporation, Limited—17,400 ordinary shares, Nos. 1 to 17,400. Halifax and Bermudas Cable Company, Limited—£97,800 4½ per cent. first mortgage debentures, within Nos. 1 to 1,200.

Brazilian Submarine Telegraph Company, Limited.—The directors of this company have to-day declared an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum, free of income-tax, for the quarter ended December 31st last, and payable on March 25th. The transfer books of this company will be closed from the 18th to the 24th inst., both days inclusive.

The House-to-House Electric Light Supply Company, Limited.—The transfer registers of this company will be closed from the 2nd inst. to the 12th inst., both days inclusive for the preparation of dividend warrants.

TRAFFIC RECEIPTS.

The Bristol Tramways and Carriage Company, Limited.—The receipts for the week ending July 25th, 1898, were £2,290 8s. 11d.; corresponding period, 1897, £2,218 7s. 2d.; increase, £72 1s. 9d.

The City and South London Railway Company.—The receipts for the week ending February 27th, 1898, were £1,065; week ending February 28th, 1897, £996; increase, £69; total receipts for half-year, 1898, £9,630; corresponding period, 1897, £9,718; decrease, £88.

The Dublin Southern District (Electric) Tramways Company.—The receipts for week ending Friday, February 25th, 1898, were £352 0s. 1d.; corresponding week last year, £508 11s. 3d.; decrease, £156 11s. 2d.; passengers carried, 61,674; corresponding week last year, 77,074; aggregate to date, £3,215 12s. 9d.; aggregate to date last year, £3,456 1s. 11d.; decrease to date, £240 9s. 2d.; mileage open, 8 miles, as against 8 miles for the corresponding period of last year. Cars, 1898, 207; 1897, 292. Miles, 1898, 18,795; 1897, 26,060.

The Liverpool Overhead Railway Company.—The receipts for the week ending February 27th, 1898, amounted to £1,300; corresponding week last year, £1,275; increase, £25.

The Western and Brazilian Telegraph Company, Limited.—The receipts for the week ending February 25th, 1898, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brasilian Telegraph Company, Limited, were £2,396.

THE KELVIN QUADRANT ELECTROMETER AS A WATTMETER AND VOLTMETER.

By ERNEST WILSON.

Communicated by Dr. J. Hopkinson, F.R.S., to the Royal Society. Received January 11th—Read January 27th, 1898.

During the past seven years the author has had continued experience with the Kelvin quadrant electrometer, both in connection with scientific research and the training of electrical engineering students in the Siemens Laboratory, King's College, London. This paper embodies a good deal of the experience which he has gained with the instrument, and he has been fortunate in that two of these instruments were available. The numbers of the instruments are 71 and 184. The writer was therefore able to test the one as a wattmeter, using the other for the purpose of investigating the instantaneous rate at which work was being done by alternate currents. The instrument used as a wattmeter (No. 184) is of comparatively recent construction, and differs from the other principally in the omission of the guard tube in the immediate vicinity of the needle surrounding a portion of the needle axis, and the wire connecting the needle to the acid inside the jar. The induction plate employed in the old form is done away with, and the terminals are permanently fixed to the quadrants in this new instrument, otherwise, so far as the author can see, they are identical. These instruments belong to Dr. J. Hopkinson, F.R.S., the old form being the same that he has used for many years, and in connection with which he read a paper before the Physical Society on March 14th, 1885.*

Verification of Clerk Maxwell's Formula.

In the paper just alluded to, it is shown that the sensibility of the instrument (No. 71) increased with the charge on the needle up to a certain point, and that for further increase of the charge on the needle the sensibility diminished. The complete explanation of this is not given, and the author believes Professors Ayrton and Perry were the first to point out that this effect is due to the portion of the guard tube in the immediate neighbourhood of the needle.

* See *Philosophical Magazine*, April, 1885.

To test this point in the new instrument a Kelvin vertical electrostatic voltmeter was placed across the needle and case, and a constant electromotive force applied to the quadrants, one pair being put to the case. The jar was then charged by sparks from an electrophorous, and readings taken on the voltmeter and electrometer scale. The charge was continually increased until disruption occurred between the needle and the lantern which supports the idiostatic gauge. Up to about 2,450 volts on the needle the sensibility increased, and so far as the author could see the needle was further deflected as the charge was increased up to the point of disruption, the spot of light being then off the scale. No great care was taken with this experiment, since it was only carried out for the purpose of ascertaining if diminished sensibility could be obtained with further increased charge. The results are given in fig. 1. In Clerk Maxwell's "Electricity and Magnetism," Vol. 1, p. 273, edition 1873, it is shown that the deflection of the needle of a quadrant electrometer should vary as $(A - B)\left(C - \frac{A + B}{2}\right)$, where C is the potential of the needle, and A and B the potentials of the two pairs of quadrants. In fig. 1 the E.M.F. between the quadrants was less

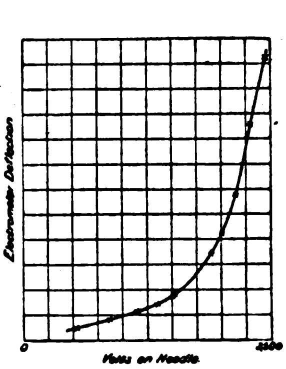

Fig. 1.

than 1 volt, and was constant. By the formula the quotient C/θ should in this case be constant, where θ is the observed deflection.

It varies in arbitrary units from 0·55 to 0·11 as the value of C varies from about 550 to 2,450 volts. This is working the instrument far beyond the range for which it is intended, since when the gauge is in proper adjustment the value of C is only about 550 volts.

In the following experiment the highest E.M.F. employed is 115 volts, and since a square root of mean square value equal to 100 volts was the maximum potential difference about to be used by the author in a certain series of experiments upon alternate current watt-hour meters, it was necessary to see that within this range of potential the formula above given is verified. The instrument was connected as before with one pair of quadrants to the case, the other pair being insulated and the electromotive forces applied to the quadrants, as also to the needle were supplied by storage cells, and accurately measured by Poggendorff's method, the standard of comparison being Clark's cell. The results are given in Table I.

TABLE I.

Observed deflection θ	A + B volts.	C volts.	$\dfrac{\left(C - \frac{A+B}{2}\right)(A+B).}{\theta}$

+ 9[illegible]7	113 0	18·1	439
			433 mean

The instrument in the above experiment was mounted on a slate base in the upstairs room of the Siemens Laboratory. The spot of light when working on this base with this instrument is never perfectly steady, and this may account for the errors observed in Table I.

Method of Test.

Fig. 2 gives a diagram of connections showing how the electrometer was used as a wattmeter for alternate currents, and how it was tested when being so used. In the formula

$$\theta = \lambda(A - B)\left(C - \frac{A+B}{2}\right),$$

where λ is a constant, it follows that if A and B are in phase with one another and with the alternate current, and have the same wave form as the alternate current; and if C is in phase with the potential

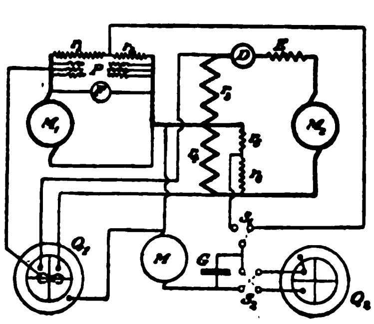

FIG. 2.

difference between two points of the circuit where the power is to be measured, and has the same wave form, A must be equal and opposite in sign to B, since the instantaneous rate at which work is done on or by the circuit must be proportional to A C or B C.

In the Siemens Laboratory there are two alternate current machines* coupled together in such manner that any desired phase difference between their armatures can be obtained. In fig. 2, M_1 and M_2 represent the armatures of these machines. On the shaft of one of these alternators is fixed a revolving contact maker, M, which makes contact between two brushes once in a period, that is, six times in a revolution of the alternator since there are 12 poles. It consists of a gunmetal disc keyed to the shaft of the alternator, and carrying two rings, one of ebonite and the other of gunmetal insulated from the disc by means of the ebonite ring. Into the ebonite ring are inserted six contact making strips of gunmetal $\frac{1}{16}$th of an inch thick, equally spaced out on the circumference and soldered into the gunmetal ring. An insulated copper brush bears on the gunmetal ring, and an insulated steel brush bears on the surface of the ebonite ring, touching each of the contact making strips as the contact maker revolves. The epoch at which such contact is made by the small steel brush can be varied and observed by means of a pointer moving over a fixed circle divided into 360 equal parts. The diameter of this revolving contact maker is 13 inches.

Q_1 is the No. 184 electrometer used as a wattmeter.

Q_2 is the No. 71 electrometer used in connection with the revolving contact maker, M, for the purpose of determining the instantaneous values of the current and potential difference.

D is a Kelvin balance or Siemens electro-dynamometer for the measurement of current; E is the thick wire circuit or circuits of the watt-hour meters being tested; F is a Kelvin multi-cellular voltmeter; r_1, r_2 are non-inductive resistances of comparatively large value for the purpose of reducing the potential difference applied to the electrometer, Q_2, when measuring potential difference, C; the pressure circuits, P, of the watt-hour meters, are placed across $r_1 + r_2$; r_3, r_4 are made up of a manganin strip 50 8 mm. wide and 0·4 mm. thick; $r_3 = r_4 = 0·2275$ ohms at about 10° C.; r_5, r_6 are non-inductive resistances of considerable magnitude for reducing the potential difference applied to Q_2 when necessary. The junction between r_3 and r_4 is connected to the case of Q_1; the quadrants of this instrument are connected respectively to the extreme ends of r_3, r_4; whilst the needle of the electrometer is connected to the other pole of M_1. In connection with Q_2, s_1 is a two-way switch for observing potentials across r_2 or r_4; s_2 is the ordinary switch supplied with the electrometer which short circuits the quadrants when moved to its central position, and in its two other positions reverses the charge on the quadrants; G is a condenser, which can be varied from 0·001 to 1 microfarad, its capacity being one microfarad during the experiments, the results of which are given in Table II.

Before giving the results of the experiments, it is well to explain the method adopted of treating the curves for the purpose of arriving at the average watts due to the alternate current, the relation between which and the deflection of the electrometer used as a wattmeter it is desired to find. It is also necessary to examine the limits of accuracy obtainable by this method. In any one experiment the frequency employed is kept constant as nearly as possible; the phase difference between current and potential is adjusted to any desired value, and the amplitude of these quantities is kept constant by observing their square root of mean square values on the instruments, D and F. The revolving contact maker, M, is then set to different positions of the phase, the number employed being at least ten equal divisions to the half period, and for each position, readings taken on the electrometer, Q_2, when the switch, s_1, is in each of its two positions. If the deflections so obtained be plotted in terms of the position of the revolving contact maker, M, the forms of the two curves are those due to the instantaneous values of the potential difference applied to the needle of the electrometer, Q_1, and the current which gives the form of potential difference applied to the quadrants of Q_1. By multiplying each of these deflections together, and by a suitable constant involving the square of the sensibility of Q_2, and the resistances, r_1, r_2; r_3 or r_4; r_5, r_6, the instantaneous rate at which work is being done by the alternate current can be inferred in watts. The average of these over a half period gives the average rate, and this can be obtained by plotting the instantaneous product and taking the area with a planimeter, or the average of the algebraic sum during a half period can be taken. The author found the latter method agreed so well with the former when the number of intervals at which observations are taken is ten, that he has adopted it in this paper, that is to say, the two electrometer deflections for a given position of M are multiplied together, the average of these taken over half a period, and such average multiplied by a constant to reduce to watts.

The best way, perhaps, to test the limits of accuracy is to adjust current and potential until they are exactly in phase. The voltmeter, F, and amperemeter, D, give the square root of mean square values, and the product of these should agree with the average results obtained from the curves. The time required to take one set of observations is generally about 20 minutes, during this time an average for volts, amperes, and frequency is taken. The author finds from experience that if care be taken an agreement between the results got from the curves, and from the product of volts and amperes, can be obtained to within 1 or 2 per cent. It must be remembered that for each position of the contact maker, *four* observations on the electrometer (Q_2) scale have to be obtained; that is, two for potential and two for current corresponding to the two positions of s_2 for each position of s_1, the difference in each case giving the net double deflection. This method is best, as it eliminates any zero error there may be. In working the electrometer, Q_2, a wooden tapper or mallet is employed, since in every electrometer there must be viscosity due to the fluid, and by gently tapping the slate base for each deflection very consistent results can be obtained. This viscosity is greater in winter, and it is advisable to keep the instrument in a warm room, although with this method of tapping the author does not find this necessary. The greatest trouble in the use of the electrometer undoubtedly arises from dust settling on the surface of the acid in the jar, thereby making the angular movement of the wire hanging from the needle smaller than it would be if such brake action did not exist. This takes place when the acid in the jar is old, and if the surface be agitated by blowing through a glass tube near where the wire dips into the acid it can be to a great extent remedied. Whatever the state of the acid the author finds he gets the most consistent results by gentle tapping. The electrometer, Q_1, is not so sensitive as the old form Q_2, and the effect due to the acid in it has not given so much trouble. The sensibility of Q_2 when the idiostatic gauge is adjusted is such that one Clark cell gives a deflection from zero of $10\frac{1}{2}$ inches on a scale 12 feet from the mirror. The potential of the needle is in this case about 350 volts.

(*To be continued.*)

* A full description of these machines is given in the *Phil. Trans. Roy. Soc.*, Vol. 187 (1896), A. p. 231.

INSTITUTION OF ELECTRICAL ENGINEERS.

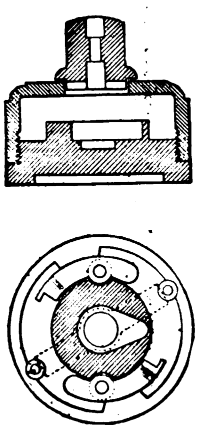
On the Manufacture of Lamps and other Apparatus for 200-Volt Circuits. By G. Binswanger Byng, Member. (Paper read February 24th, 1897.)

(*Continued from page* 272.)

Without enlarging upon the subject of switches to an undue extent, I will show some specimens of different types I find to be satisfactory in practice.

Here (1) is a switch to take the place of the ordinary link or tumbler switch, and (2) here is an ordinary double-break china switch. You will notice the formation of the china base, and the

H.V. DOUBLE BREAK SWITCH



H.V. WALL PLUG

Fuses.

separation and action of the metallic parts, which are arranged to produce a long break and perfect insulation, so that an arc cannot be maintained if established, nor can a shock be communicated to the operator. I have also placed there enlarged drawings of wall sockets and ceiling roses, to illustrate my further remarks under this heading.

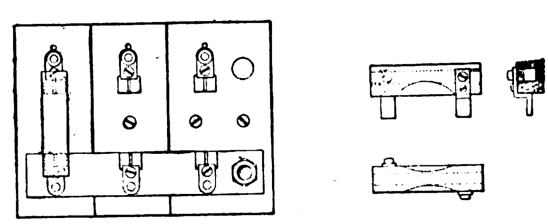
It is not necessary to go deeply into the subject of fixtures such as electroliers, pendants, &c., but in connection therewith I wish to refer to the question whether it is advisable to recommend the use of two or more low-voltage lamps in series on a 200-volt circuit. Within my own experience, I know of several installations fitted originally with 200-volt lamps that have, by reason of greater expense for current, and an inferior light, been re-wired for two 100 lamps in series, with satisfactory results. It is within the province of manufacturers to materially assist wiremen by designing fittings specially adapted to series wiring, such as series holders, ball fittings, brackets, or electroliers with arms in multiples of two, and such a practice might be extended with advantage to many other details.

The question of fuses for higher voltage requires more careful investigation, and would repay thorough discussion. Central station engineers agree to differ upon the various points of efficiency, as evidenced by the different rules issued for our guidance. Some lay stress upon increasing the length of fuse wires, others insist upon ventilation holes, and in some cases the height of covers are to be increased. But there is no unanimity between them, and none of these rules, in my opinion, indicate the right direction.

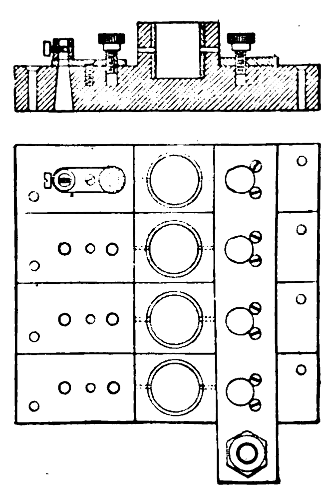
I have made some extensive experiments, and believe that the results are of interest to the profession generally.

When a circuit is opened by the disruption of a fuse, the combined metallic vapours and hot air produced by the high temperature of the resulting arc may extend and maintain it so as to bridge over the terminals which, melting and becoming volatilised, feed the arc, and rapidly increase the temperature. I find, in practice, that under these conditions the china base supporting the fuse and terminals is easily volatilised also, and not only contributes towards the maintenance of the arc, but is ruptured as if by explosion, tending to set fire to any inflammable surroundings. This rupture has hitherto, I believe, erroneously been attributed to the expansion of air confined by the cover, hence the ventilation holes, which, according to my opinion, are useless. The same experiments tend to prove the fallacy of using a long fuse wire, with the concomitant disadvantages of finding space for it, and also difficulty in renewal; and I feel sure that full efficiency may be attained with a short fuse.

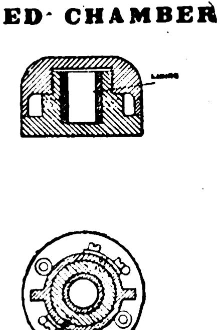
H.V. CUT OUT BOARD
SPRING CLIPS FOR HOLLOW CHINA FUSE HOLDERS



H.V. CUT-OUT BOARD WITH LINED CHAMBERS



H.V. CHINA CUT-OUT LINED CHAMBER



My deductions from the aforesaid experiments are that:—

1. It is essential to arrange a fuse wire so that it will break at a definite part of its length, *i.e.*, approximately, the centre.

2. The arc formed on breaking the fuse must be so confined that it cannot be maintained so as to damage the terminals, base, or cover.

I will now describe how I have carried out these essential points in china cut-out boxes, which are the general type of fusible cut-outs used in house installations in this country.

These fuses are arranged on china bases or in groups upon cut-out boards, and their carrying capacity varies from 1 to 100 amperes. In all these I provide what I call a "fuse chamber"—*i.e.*, a round china wall forming a central hole, from ½ to 1 inch in diameter—and this is pierced with two holes near to the terminals, which are fixed upon the base outside the wall. The wire is threaded through the holes from one terminal to the other, passing through the fuse chamber. Both ends of the fuse wire are supported by a material which is a better heat conductor than air, whilst it is free in the central fuse chamber. Thus the same current raises the temperature of the fuse wire within the fuse chamber more rapidly than at the supported ends, therefore the disruption takes place there, and the resulting arc is enclosed. I find, however, that china as an isolator is not sufficient, because of its tendency to volatilise under the high temperatures—a fact I have already mentioned. Therefore I line the interior of the chamber with another material which is a better heat conductor and less liable to fracture, and I find that ordinary plaster of Paris is most convenient for this purpose, although several other substances may be equally efficient.

Fuses constructed on this principle require but a short length of wire, and are perfectly safe on high voltages, and the general appearance and size does not differ to any great extent from those now in common use. The principle once established of surrounding part of the length of fuse wire with a substance that is a better conductor of heat than air, we can easily construct any other type of fuse upon the same principle.

Fuse wires enclosed in glass tubes filled with plaster or cement, but with a free central space for fusion, for instance, fulfil the same conditions.

I find that such fuses have been patented by Mr. Mordey in 1890. The mere fact of enclosing a fusible wire in a non-conducting refractory filling would not fulfil the essential functions of a perfect fuse as I have described, without a clear space at or about the centre for disruption. Mr. Mordey describes such a space in his specification, but it is for the purpose of observation only, and it is not clear, from the tenor of the specification, that the inventor had this purpose of the localisation of fusion in mind. Mr. Miller, of Kensington, has also altered the ordinary Edison fuse by substituting thin copper wire, and partly filling the centre with asbestos fibre. So far as localising the point of disruption and confining the arc, this fuse acts very well, although copper or alloyed fuses are not perfect under any circumstances, by reason of the maintenance of a dull red heat under normal load.

Arc Lamps.

Coming, now, to the subject of arc lamps in relation to the higher pressure, I do not see that, with alternating currents, the increased potential materially affects the consumer. The practice may bring a single-parallel system into vogue, with economy coils—an alteration which will, in my belief, increase the commercial efficiency of alternating arcs. But the disadvantages are apparent in the case of a continuous current circuit. For instance, in small installations of one or two lamps on the 100-volt circuit, these must be doubled on the 200-volt circuit, or useless resistances interposed. To equalise the conditions it has been proposed to substitute low current lamps, say, four 5-ampere instead of two 10-ampere lamps.

As this substitute has been advocated by one of the foremost central station engineers, and many others will possibly follow him, it may be useful and not out of place to prove that both in theory and practice low current arc lamps are deficient in points of economy and efficiency.

It is generally accepted that the current density of an arc is independent of its size; assuming this as correct, the area of an arc must be proportional to the current, and the cooling surface proportional to its diameter. This is the case with the cooling surface of the carbons, if these are used of areas proportional to the current taken by the lamp. Thus the cooling effect of the atmosphere will have a direct relation to the diameter of the arc and to the square root of the current. Therefore, for illumination, large arcs are more efficient than small ones, and the practical arc is attained when the benefit of increasing the number of light centres balances the inefficiency of small arcs. This gives, in practice, an arc of about 10 amperes.

Small arcs worked under same conditions are more unsteady than large ones, which is due to the fact that with an arc of a given length the E.M.F. decreases as the current increases. An experiment in which a fixed length of arc at 5 amperes and 44 volts was suddenly increased from 5 amperes showed—

Normal	5 amperes	44 volts.
Sudden increase from	5 to 6 amperes ...	40·5 „
„ „	5 „ 7 „ ...	38·5 „
„ „	5 „ 8 „ ...	37·2 „
„ „	5 „ 9 „ ...	36 „
„ „	5 „ 10 „ ...	35·2 „

So an arc, or series of arcs, with a total voltage approximating to the E.M.F. of the circuit is unstable and fluctuating—probably due to the disproportionate variations of the cooling surface, coupled with the decreased resistance of carbon at higher temperatures. If the arc flares, the current will increase, unless there is sufficient resistance in series to reduce the voltage across the arc at a greater rate than the above figures show. Certainly the mechanism tends to lengthen the arc, but to no advantage because the movement continues until the current decreases to the normal value, and the acceleration would extinguish the arc unless an interposed resistance allowed of a rapid increase of the voltage across the arc. Such a resistance is necessary to compensate the "negative resistance" of the arc, which may be more appropriately termed "decreased cooling surface per ampere." An additional resistance in series is necessary to ensure steadiness. It follows, therefore, that 5-ampere lamps must be worked on a higher E.M.F. or "pumping" will ensue.

(*To be continued.*)

TEST OF THE CHICAGO STORAGE BATTERY ROAD.*

The carefully conducted test of the plant of the Chicago Electric Traction Company furnishes the most valuable data at present obtainable regarding the application of the storage battery to street railway service. The vital question of the cost of battery maintenance is still an open one, yet the batteries tested have shown a better record than any of their predecessors. The results of the tests make a good average, showing just about what might be expected from a trolley road operating under the same conditions.

It may be well to preface the test with a sketch of the history of the company and a description of the equipment. The conception of the road was for the purpose of booming real estate in the south-western portion of the city. The company was chartered early in 1894 with a capital stock of $2,500,000, and almost from the beginning it has laboured under financial difficulties. In 1895 a majority of the bonds were placed with parties interested in the manufacture of storage batteries with the understanding that battery cars should be run. The company owned six franchises, covering 36 miles of streets, but nearly all the tributary territory is very sparsely settled. In a short time the company became insolvent, and in January, 1896, G. Herbert Condict was appointed receiver. Under foreclosure proceedings the road was sold at public auction October 12th, 1897, to J. S. Bache for $260,000. E. R. Gilbert was appointed general manager of the company. Some idea of the traffic of the road is given by a statement of the receipts and expenditures in the receiver's report:—

	Passengers and miscellaneous.	Operating expenses.
January to June	$4,972	$9,188
June	2,482	3,224
July	6,045	4,609
August	7,045	6,048
September...	6,347	6,584
October 1 to 12	2,254	2,880

The main line extends from the northern terminus at South Park Avenue and 63rd Street, the intersection with the Alley L, south to Englewood, Washington Heights and Blue Island, and a branch runs from Morgan Avenue West through Morgan Park. The line passes several summer resorts and three cemeteries; a large summer traffic results from the former, and for the latter a car, specially designed for funerals, is in operation. On the Morgan Park line a grade of 9·3 per cent. is encountered for a distance of 371 feet on Prospect Avenue. This gradient was insurmountable for a car equipped with one 50-H.P. motor geared to one axle only. A counter weight system was installed which is almost a duplicate of the one in Providence, R. I., designed by M. H. Bronsdon and J. P. F. Kuhlman, and described in the *Review*, April, 1896. There are 23 miles of track now laid, of which 19 miles are double.

After the decision to use storage batteries was reached, B. J. Arnold and J. H. Vail were employed as engineers to plan the entire system. All the designs follow the most approved line of engineering practice, and no pains were spared to make it a model of its kind. From the boilers to the batteries everything was designed with a view to economy and convenience. Perhaps this is the first time that the storage battery has been given an honest and prolonged trial in this country, and if it is capable of successful operation in street railway service it should be demonstrated in this system.

The track, which was constructed by C. E. Loss & Co., is the very best, for this was essential to long life for the battery plates. Johnson 7-inch girder rails, weighing 80 lbs., and resting on tie plates, are joined by 6 bolt fish plates with tie rods at every joint. Oak ties, 8 feet long, are placed 2 feet between centres, and rest on 6 inches of gravel ballast. The construction, with the absence of trolley wires and rail bonds, appears as though it were intended for steam traffic.

The power station is worthy of note, for it is certainly different in many respects from any other railway station. It is not necessary to locate the power house at the "centre of gravity" of the system to get the most economical current distribution, so a site was selected at 88th Street and Vincennes Avenue, convenient to the Rock Island railroad, and where land is cheap and transportation for fuel good. Car tracks run through the loggia, and above this are the offices, locker room, shower baths, toilet rooms, and waiting rooms for the employés.

Unlike street railway stations in general, the dynamos are not all of the same voltage, for it is necessary to have three circuits of different potential to charge the batteries properly. Four six-pole, 190 kw., shunt wound Walker generators, with a variable voltage between 160 and 190, were installed. This is the ultimate dynamo capacity of the station, the fourth machine being held in reserve. The dynamos are direct connected to two 250-H.P. Willans engines, the kind so generally used in the electric power stations of Great Britain. These two engines are at either end of the room, and a third one, of 500 H.P., will be put in the centre. To give the most flexible arrangement, the Arnold system of power station construction was adopted. A solid shaft with couplings extends from one engine to the other. The armatures of the generators are fixed to quills, which are free to rotate about the solid shaft. This makes a very complete and compact engine generator installation, a 1,000 H.P. plant occupying a floor space only 12 feet × 56 feet. Each engine has two sets of cylinders, the cranks being opposite to one another. The steam, entering the high pressure cylinder, from the steam chest, expands through the hollow piston rod into the receiver space below, ready to act on the following piston. An air cushion takes up the momentum of the moving parts and permits a speed of 380 r.p.m., without excessive noise or vibration. The speed is regulated by a throttle valve in the steam pipe controlled by a centrifugal shaft governor.

Just to the rear of the power units is the white marble switchboard, consisting of five panels, one for each generator and the fifth for the motor switches. There are four bus bars, the three lower ones being for the high, medium, and low voltages, and the top one

* *Street Railway Review.*

the common negative bar. Each panel has two switches, one for the negative lead of the generator after it has passed through a recording ammeter and circuit breaker, and the other switch can be turned through a semi-circle making connection with any of the three positive bus bars. Weston illuminated dial ammeter and voltmeter and a resistance box for controlling the voltage are attached to each generator panel. From the motor panel the circuits are controlled which run to the two battery transfer cars, the car transfer tables in the basement, to the cooling tower motor and the other motors in the building. By means of the circular switch in the centre of the motor panel, the motor bus bars can be connected to any of the three positive bus bars, or the motors can be operated from the car batteries when the generators are not running. The engine room presents a very attractive appearance, being finished with white marble floors and wainscoting, and visitors' gallery.

The passageway to the boiler room is behind the engines and by the condensers in the basement. There are three 200-H.P. Heine water-tube boilers, with room for three more. Coal is delivered on a side track back of the boiler room, where it is intended to have the fuel transferred direct from the cars to the iron platform in front of the boilers, about 7 feet above the floor. From here it is shovelled into the hoppers of the Roney stokers.

The smoke stack, which is located about 30 feet outside the building, is constructed of steel, is self-supporting, 7 feet in diameter and 150 feet high. It rests on a brick foundation, raising it to 22 feet above the ground. Connection to the boilers is made through an iron flue back and above them and through a brick flue entering the brick base of the stack. A Green fuel economiser, having 192 tubes, is in the brick flue; a by-pass is also provided for service when the economiser is not in use. Adjoining the stack is a Worthington cooling tower, 12 feet in diameter and 30 feet high. The condenser pump delivers the condensed steam and heated injection water to the top of the tower, and here, by means of revolving pipes turned by the pressure of the escaping water, it is sent in sprays over the tops of sewer tile set on end in tiers. During warm weather a large fan, driven by a Siemens-Halske motor, cools the water by evaporation, so that when it collects in the condenser well its temperature is about 80° F. The feed-water pipe taps into the condenser discharge before the pipe reaches the tower.

The supply of feed-water comes from an artesian well and from the city mains, but by the arrangement of the jet condensers and the cooling tower, the amount taken is only sufficient to make up for the waste due to evaporation. The water can be taken through a heater, which receives the exhaust from the auxiliary pumps, and through the economiser into the boiler, or either of the heaters can be cut out if necessary. The economiser not only heats up the water to the boiling point, but also acts as a reservoir with a supply of hot water which increases the duty of the boilers. The steam is supplied to each engine through a 6-inch pipe, having a copper expansion bend, and the engine exhaust is conducted to jet condensers.

The most unique and interesting features of the plant are to be found in the battery room, which is in the basement under the car barn. The car battery consists of 72 cells arranged in 12 rows of six each. These cells each have nine plates, 7¾ inches wide and 14⅛ inches long, five of which are negative of the "Chloride" type and four positive of the "Tudor" or "Manchester" type. The positive plates are $\frac{5}{16}$th inch and the negative ½ inch thick. Each cell, including plates, electrolyte and hard rubber jar, weighs 100 lbs., making the total weight for a tray 7,800 lbs. The plates are connected by electrically welded lead strips in four groups of 18 cells, each group being joined by flexible cables to two large brass plates on the sides of the trays. A loose fitting rubber crate over the top of the batteries prevents the electrolyte from splashing out of the jars.

By means of the three separate generator circuits the batteries can be charged at three different potentials as the counter electromotive force in the battery rises. The discharged battery is first connected to the 160-volt main with a current of 150 amperes flowing. The current decreases as the counter electromotive force increases, and when the current diminishes to 30 amperes, the battery is switched into the 172-volt circuit. The current jumps to 150 amperes, and diminishes again, and then the terminals are transferred to the 176-volt circuit. This operation can be accomplished in about 40 minutes, although a slightly better battery efficiency is shown when the time is longer.

After the batteries are charged the next important step is to get them in the cars expeditiously, and this is accomplished by a travelling carriage which runs along the track in the alley alongside the battery tables. On either end of the carriage is an elevator with rolls on top which are operated by bevel gears. Similar rolls are on the charging tables, which can be coupled to the elevator rolls and the trays automatically shifted. In the middle of the carriage is the operator's platform, with a controller for each of the motors, two of which are for the rolls, one for each elevator and one to run the carriage along the track.

When a discharged battery on a car is to be replaced a charged one is rolled upon one of the elevators and the carriage is run to a position where the vacant elevator is directly beneath the track in the loggia. The car, at the end of each round trip, runs into the correct position, which is determined by the vertical position of a lever the conductor lifts so that the front bumper of the car just touches it. The vacant elevator of the carriage is raised and the discharged battery released from the car by pulling a lever. When it is lowered the carriage is advanced so that the charged battery is beneath the car truck. The battery is elevated, the hooks automatically engaging the cross bars and the brass plates on the sides of the trays making a sliding electrical connection with the spring clips on the car trucks which are the terminals of the controller cables. The entire operation can be performed in 50 seconds, although the customary time is a little over a minute. The carriage then carries the discharged battery to an empty charging table, where it is rolled from the elevator and makes electrical connection with the charging circuit. The battery room, although well ventilated, is filled with the fumes of sulphuric acid. This disagreeable condition could probably be obviated by having hoods over the charging batteries and the fumes conveyed to the stack.

There is provision in the car barn at present for 28 cars, but it will be extended eventually to accommodate 50 cars. The transfer table, operated by an electric motor, runs on a track down the centre of the barn. No special tools or preparations have been made for repairs. Besides the regular equipment of cars, a 3,500-gal. sprinkler is provided for summer and a snow plough for winter.

The motor cars are mounted on Dupont trucks, made by the Johnson Company. Each truck has two bars running across the frame and engaging hooks, formed by bending over four 5-inch channel irons, which pass under the tray. A 50 H.P. Walker motor is suspended on the outside of the car axle. The controllers, made by the Walker Company, had to be of special design for the service, as the low voltage necessitated large currents. There are five points: the first combines four sets of batteries in parallel, giving 36 volts; the second gives 72 volts with the cells in series-parallel; the third puts the batteries in series with resistance; the fourth cuts out the resistance but leaves the batteries in series, and the fifth shunts the motor field with the batteries in series.

During the summer of 1897 over 20 motor cars were operated, often with trailers, and when the winter schedule of nine cars was instituted, Mr. Condict, then general manager of the road, decided to make a complete test of the road and power house to determine the most economical methods of operation. Under the direction of George A. Damon, who was assisted by Prof. Gaylord and a corps of students from the Armour Institute, three complete tests were conducted under actual operating conditions. The following is an abstract of the report of the tests for which we are under obligations to Mr. Condict. We are also indebted to Mr. Damon for courtesies extended.

Test of Power Plant.

The equipment of the power house has already been described. In preparing for the tests all proper precautions were taken to secure accurate data. The apparatus used was carefully calibrated. The water was measured by means of three tanks just before it entered the feed pumps. The steam used by the stoker engine, by the economiser engine, by the calorimeters, by the feed pump, and by the air pump was condensed and carefully measured. The blow-off from the boilers and other unused piping was opened up to guard against the water escaping through unknown leaks. All water not accounted for by the auxiliaries was charged against the engines, with the exception of a liberal allowance for leakage in the live-steam line.

The first test was with the plant running with two boilers, two engines and three generators. The second test was with practically the same load carried by one boiler, one engine and two generators, while the last test was made under practically the same conditions as the second test, with the exception that the three-voltage method of charging the batteries was abandoned. In this test but one generator was used, and the batteries were charged in successive sets, all at a common potential, the voltage being raised as the batteries became charged in such a way that the load upon the generator was kept nearly constant.

The coal used was from Fairmount, W. Va., and cost, delivered at the power house, $1.90 per ton. An average of five determinations of its calorific value by the Berthier method gave 10,145 British thermal units per pound. The average of six analyses gives the following result:—

Moisture	6·326 per cent.
Volatiles and combustibles	32·903 „
Fixed carbon	48·126 „
Sulphur	2·700 „
Ash	10·030 „

Card No. 7.—Taken 3.15 p.m. on November 26th, 1897.

THE MAGNETIC PROPERTIES OF ALMOST PURE IRON.

By ERNEST WILSON.

Communicated by Dr. J. Hopkinson, F.R.S., to the Royal Society.
Received January 11th. Read January 27th, 1898.

One of the two rings of almost pure iron supplied by Colonel Dyer, of the Elswick Works, to Sir Frederick Abel, K.C.B., F.R.S., by whom they were sent to Dr. John Hopkinson, F.R.S., has already formed the subject of a communication,* and is herein referred to as Pure Iron I. As this pure iron has not been directly tested for dissipation of energy due to magnetic hysteresis, and the second ring was available, the author thought it would be interesting to examine its magnetic properties: it is referred to as Pure Iron II. The substances other than iron in this specimen are stated to be—

Carbon.	Silicon.	Phosphorus.	Sulphur.	Manganese.
Trace.	Trace.	None.	0·013.	0·1.

This ring has an internal diameter of 3·2 cm., an external diameter of 4·5 cm., a depth of 2·6 cm., and is wound with 61 turns for the secondary coil next the iron, and 49 turns for the primary or magnetising coils. The method of test † employs a ballistic galvanometer, and is that in use in the Siemens Laboratory, King's College, London, where the present experiments were carried out. The currents in the primary circuit were supplied by storage cells, and measured by balancing the potential difference due to such currents in a standard resistance against a Clark's cell. The current meter in the circuit was only used for convenience of adjustment.

Quoting from the communication above referred to, Pure Iron I. gives the following induction curve at atmospheric temperature:—

B....	84	118	467	2,700	7,060	10,980	14,160	15,590	16,570	17,120	17,440
H....	0·15	0·38	0·60	1·06	2·11	3·77	7·48	13·36	23·25	33·65	44·66

Pure Iron II. has been tested under two conditions: (*a*) as received, and (*b*) after careful annealing. The results are given in Table I, which also contains the results obtained by Prof. Ewing from a sample of transformer plate rolled from Swedish iron.‡ The figures of Prof. Ewing relating to magnetic hysteresis are exceptionally low, and although annealing has considerably improved the Pure Iron II., it is still slightly inferior to the transformer plate. On the other hand, the permeability μ of this pure iron after annealing is exceptionally high, having a value 5,490 for B = 9,000. The coercive force for maximum B = 15,270 is 1·13 C.G.S. units.

* *Roy. Soc. Proc.*, Vol. 52, p. 228.
† *Ibid*, Vol. 53, p. 352.
‡ *Proceedings Institution of Civil Engineers*, Vol. 126, p. 185.

Table I.

Limits of B in C.G.S. units per square centimetre.	Dissipation of energy by magnetic hysteresis in ergs per cycle per cubic centimetre.					
	Transformer plate rolled from Swedish iron (Ewing).		Pure Iron II. tested as received.		Pure Iron II. tested after annealing.	
		μ.		μ.		μ.
2,000	220	2,560	350	2,000	262	2,500
3,000	410	3,340	500	2,730	460	3,190
4,000	640	3,880	800	3,330	720	3,810
5,000	910	4,230	1,100	3,700	1,010	4,350
6,000	1,200	4,410	1,450	4,138	1,350	4,800
7,000	1,520	4,450	1,760	4,375	1,670	5,380
8,000	1,900	4,330	2,160	4,445	2,020	5,440
9,000	2,310	4,090	2,600	4,615	2,450	5,490
10,000		3,790	3,100	4,545	2,860	5,460
12,000			4,400	4,000		4,900
14,000			5,900	2,641		3,260
15,000				1,415		2,050

The figures in Table I. relating to Pure Iron II. after annealing have been obtained by interpolation from the actual observed data given in Table II. An induction density of 15,270 for H = 9·24 is higher than the author remembers having seen. In fact, for values of H below about 10 or 12 this specimen is exceptionally good, as is shown by the very high permeability.

Table II.

Limits of H.	Limits of B.	$\frac{1}{4\pi}\int H\,dB$.	μ	Coercive force in C.G.S. units.

Apparent Magnetic Instability.

Whilst making the foregoing experiments, the author noticed how great was the apparent magnetic instability in this specimen, and thought it worth to investigate this more closely.

It has already been noticed, and is well known, that if the magnetising force be varied from one maximum value through zero to a value equal, say, to the then coercive force of the material, that tapping the specimen will produce a considerable change of induction; or if the observed kick on a ballistic galvanometer (in circuit with a secondary coil wound on the specimen) due to such change be added to the observed kick when the magnetising force is raised to the opposite maximum, the sum does not equal the whole kick which would be observed if the force were at once varied from the one maximum to the other. During the interval the magnetism appears to continue to settle down, so that the change which lastly takes place is not so great as it would be if such apparent settling down did not occur.

Experiments were made to investigate the effect when the limits of B were (*a*) large and (*b*) small. It is assumed that the instrument gives the true time integral of current.

(*a*) Maximum B = 15,270, coercive force 1·13 C.G.S. units. The maximum force, H, of 9·24 C.G.S. units, was suddenly varied through zero to 1·13, and the secondary circuit kept closed until deflections to the left and right were observed, the periodic time of the galvanometer needle being 10·6 seconds. The scale is graduated from 0 on the left to 1,000 on the right, and the readings taken were 351, 623, giving a difference of 272, corresponding to a change of induction per square centimetre of 12,630 C.G.S. units. When the magnetism had settled down, as was shown by closing the secondary key with no extra resistance in its circuit, and observing no deflection on the ballistic galvanometer, a suitable extra resistance was inserted, and the force suddenly raised to its maximum value, the observed deflections are 362, 627, the difference 265 corresponding to B = 12,350. These results were many times repeated.

The total change of induction produced a deflection 662, 330, the difference 332 corresponding to B = 15,270. We have, therefore, to account for a difference of 5,560, or 18 per cent. of the total change from one maximum to the other. The zero, when the spot of light is perfectly steady, is 495, and we can see that when making the first change from one maximum through zero to force, 1·13 the deflection to the left is 143 as against 128 to the right; whereas, when making the second change, the deflections are 133 to the left and 132 to right. There is evidence here of a change of continuing in the same direction, since the first elongation is greater than the second, and the decrement would only account for about 1 per cent.

This effect was next observed in a slightly different manner. The change of force from one maximum through zero to the then coercive force was effected, and the secondary circuit closed at known intervals of time after such change. The results are given in Table III.

TABLE III.

Time in seconds ..	0	1	2	3	4	5	6	10
Change of B, 10 cells exciting through extra resistance	13,600	4,030	1,990	927	576	285	175	42
Change of B, 56 cells exciting through extra resistance	13,800	3,690	1,680	944	529	256	...	40

It will be seen from the figures that about 30 per cent. comes out after the first second has elapsed, and that the result is practically the same, whether the charging potential difference be that due to 10 or 56 cells. With a total reversal from one maximum to the other no such effect was observed, the change taking place immediately. Having taken the force from one maximum through zero to a value equal to the then coercive force, the specimen was tapped four times with a piece of wood, and at each stroke it delivered 105, 40, 56, 30 C.G.S. units per square centimetre in the direction of acquirement of magnetism.

(*b*) Maximum B = 3,770, maximum H = 1·003. The force was varied from one maximum through zero to 0·620 and a deflection corresponding to B = 3,620 observed. The figures in Table IV. give the results obtained by closing the secondary circuit at known intervals of time after reversal.

TABLE IV.

Time in seconds	0	1	2	3	5
Change of B, five cells exciting through extra resistance ...	3,620	536	95	25	10

One would expect the maximum induction to be affected in this case, since it is on the steep part of the curve: the figures obtained are given in Table V.

TABLE V.

Time in seconds	0	1	2	3	5
Change of B, five cells exciting through extra resistance ...	3,770	796	23	14	6·5

The curve in fig. 1 shows this effect clearly; the points 1, 2, 3, for any force show the observed change of induction density B when the secondary key is raised ½ second, 1 second after reversal, and kept down permanently as in the ordinary way. When observing the deflections for the curve in fig. 1, the five cells used for exciting had placed across their terminals a condenser of 4 microfarads capacity.

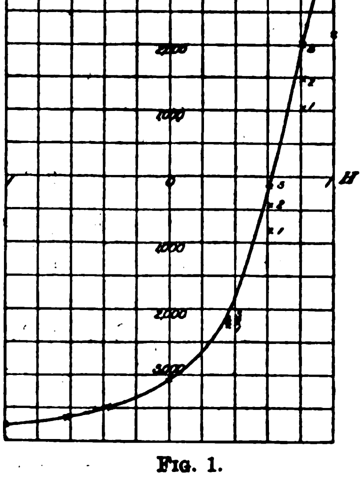

FIG. 1.

We are dealing with a very steep curve in these experiments, that is to say, the rising portion for the large forces is very nearly perpendicular. We observe that it is on the steep portions that these effects have been noticed, and such effects could very easily be produced by a slow change in the magnetising force. Such slow change might arise from the heating of resistances in the circuit, if these be of carbon; this was looked into, and only metal resistances used. The self-induction of the circuit might, if large enough, delay the magnetising current, and produce the effect. We have seen that it is practically the same, whether the applied potential be that due to 10 or 56 cells. In any case the self-induction can be approximately calculated in our case. Take the curve in fig. 1—we see B increases 5,750, whilst H increases 0·6. The total change is 9,860, since the cross sectional area of the specimen is 1·715 sq. cm. H = 0·6 corresponds to a change of 0·117 ampere, and, taking the volt as our unit and the primary turns at 50, we find L = 4·21 × 10⁻⁸, where L is the coefficient of self-induction. If E be the applied potential and R the resistance of the circuit, the current at any time, *t*, after closing the circuit, can be expressed by $\frac{E}{R}(1 - \epsilon^{-\frac{R}{L}t})$. For $t = \frac{1}{2}$ second the current has its maximum value within an exceedingly small quantity. But the method of experiment enabled one to test the rapidity with which the current rises to its maximum value. Let a balance be made, say, when the current is such that the force is equal to the coercive force of the material. Now suddenly reverse the force from its maximum through zero to this value. The immediate depression of a key tells at once if the current is still balanced. The current, immediately after reversal, that is to say, within ½ second, had certainly attained its normal value to within 0·3 or 0·4 per cent.

The condenser had no material effect upon the rapidity with which the current attained its maximum value. We can only conclude that the effect is peculiar to the iron itself, and might be influenced by induced currents, since the ring is not subdivided. The subject of propagation of magnetism as affected by induced currents has been dealt with in the case of a magnet having a core 12 inches diameter,* and a magnet having a diameter of 4 inches.† Imagine that the cross section of our pure iron specimen is circular instead of rectangular—it would have a diameter of 14·8 mm. If we assume equal conductivities and magnetic properties, we can infer, roughly, from the 12 and 4-inch magnets, what the effect of induced currents in our specimen would be.

Take the 12-inch magnet. For reversal of maximum H = 2·4 the effects had died away in about 400 seconds. Similar events will happen in the pure iron core, but at times varying as $\left(\frac{14\cdot8}{305}\right)^2$: that is, we should expect the effects to have subsided in 0·85 second.

Take the 4-inch magnet. For reversal of magnetism H = 1·7, the effects had subsided in about 40 seconds: $\left(\frac{14\cdot8}{101\cdot6}\right)^2 \times 40$ gives 0·94 second.

It is, therefore, probable that the induced currents in the Pure Iron II. may have something to do with the effects observed in this paper, although it is difficult to account for such times as five and 10 seconds, unless the molecule itself is considered. This effect has been observed in laminated specimens.

The difficulty of working with alternate currents, if the core be subdivided, in order to investigate the effects observed, using the method in the *Proceedings of the Royal Society*, Vol. 53, p. 352, is the necessity for the very accurate control and measurement of the magnetising force. Small variations of this force would at once mask the effects observed. In the paper just mentioned a considerable difference was observed between cyclic curves obtained with the ballistic galvanometer, and by means of alternate currents having frequencies of 72 and 125 per second in the case of a laminated hard steel ring for maximum B = 16,000. On the other hand, no such difference was observed in the case of a laminated soft iron ring when maximum B was 4,000.‡ It would seem from the experiments in this paper that the amplitude of induction would not be so great for high frequency and small induction density, B, and this is of importance in the case of iron cores for transformers. It is worth noting that when working on solid rings with the ballistic galvanometer, induced currents may account for apparent magnetic instability.

Mr. H. H. Hodd has helped me in the experimental part of this paper, and I here wish to tender him my thanks.

A $1,000,000 GUTTA-PERCHA SCHEME.§

THE Gutta-Percha Corporation, Limited, with $1,000,000 capital, was "floated" in London in December. The object is to acquire the Sérullas patents for extracting gutta-percha from the leaves of the *Isonandra dichopsis* and other trees of that family.

The London *Financial Times*, not inaptly, headed its notice of the new corporation "Stale Eggs for Sale." Readers of the *India-Rubber World* will remember that, so long ago as 1892, Hippolyte Eugene Sérullas, who had gone to the East Indies at the expense of the French Government to report upon the gutta-percha supply, read before the Société d'Encouragement pour l'Industrie Nationelle, an account of his discovery of a method of extracting pure gutta-percha from leaves and twigs, instead of destroying the trees, as is so common in Borneo. Patents were granted subsequently to Sérullas, in conjunction with Felix E. Hourant, in several countries, and the rights under these patents are involved in the above scheme. In England two patents were granted—No. 11,116 of 1892, and No. 654 of 1896. In the United States there is one patent—No. 575,739. In spite of the publicity of M. Sérullas's idea for so many years, and the fact that the owners of the patents have been ready at all times to realise upon them, the fact that no attempt has been made to work the idea on a commercial scale implies a general lack of confidence in its value.

But Sérullas is not alone in having a method for extracting gutta-percha from leaves. Another Frenchman—Dieudonné Rigole—has been in the field with a patent for this purpose for several years.

* *Journal of Proceedings of Institution of Electrical Engineers*, Vol. 24, Part 116.

† *Phil. Trans.*, Vol. 186, A, pp. 93—121.

‡ See *Electrician*, September 9th, 1892.

§ *India-Rubber World.*

The British issue was No. 4,252 of 1892. The *India-Rubber World* in September, 1893, published a prospectus of the Gutta-Percha Manufacturing Company, with $600,000 capital, to exploit Rigole's method. Nothing coming of this, the Borneo Gutta-Percha Plantation and Produce Company, Limited, with $300,000 capital, was projected, as we reported in May, 1894, but nothing more has been heard of that enterprise.

By the way, the new Gutta-Percha Corporation excepts Brazil from the scope of its operations, the G. P. Brazil Syndicate. Limited, having been registered in London on April 1st, with £5,000 capital, to acquire and develop the rights of Sérullas, so far as they relate to Brazil, in the process for extracting gums from the leaves of trees. The intention is to apply the method to India-rubber. But while all the terrestrial rights under these patents have been monopolised, no doubt the vendors would entertain negotiations for rights to develop the patents on all the seas, in the milky way, and on the next comet that may be headed toward this planet. These might afford a richer field than even the forests of Borneo.

"THE COMING OF THE ELECTRIC HORSE."

Lecture by Prof. S. P. Thompson.

This was the subject of an address delivered on Thursday evening in the Agricultural Hall, Wolverhampton, by Prof. Silvanus P. Thompson, D.Sc., F.R.S., Principal of the City Guilds Technical College, Finsbury, and who is this year president of the Wolverhampton Literary and Scientific Society. The address was exceedingly interesting. Prof. Thompson pointed out that we are reaching the limit of the capacity of steam power, and therefore we must look around for something superior, and that he affirms is electricity. We are, in fact, entering upon a revolution quite as momentous as that of the supercession of animal power by steam power. Electricity has served us in telegraphy for about 50 years, and in lighting for about 20 years, but its use in heavy motive power is just beginning. As far back as the time of the wedding of the Prince of Wales, London Bridge was illuminated by arc lamps, but it was at enormous cost, the energy being derived from Grove's batteries, now we use dynamos. The latter became possible as early as 1831, when Faraday discovered the mechanical mode of generating electricity, by the motion of a magnet within or around a coil of wire, but it was not till 1878 that this motion was supplied by the steam engine. Then it was that electricity began to be available for use on a large scale of lighting, and for heavy mechanical work. The first electric lighting station put up in London was at Paddington Railway Station, and the dynamos there constructed, are still at work. Since then, however, the capabilities of electric lighting plant has enormously extended, and in one generating station, 30,000 horse-power is constantly employed. Many of the larger dynamos consisted of a pulley, girt with wire coils, and rotating within a circular frame, fitted with magnets. Electric motors of 50 H.P. had an efficiency of 92 per cent., with only 8 per cent. of waste, and motors of over 200 H.P. had an efficiency of 97 per cent. In the case of steam power unaided by electrical transmission, the efficiency was much lower. In one notable instance of eight engines of 40 horse-power average, the loss of energy in transmission through belting and shafting was 43 per cent., or nearly one-half. The works of the Electrical Construction Corporation, Wolverhampton, were the first in England to be fitted with electrical motors. The principle was being extensively applied to machine tools, and thousands of pounds were saved annually in consequence. A firm in Chester applied electricity to the cranes used for the carrying of steam billets, and in this case not only were the cranes moved by electricity, but the billets were raised by electro-magnets in place of the customary attachments of chains. Here a great saving of time, labour and fuel was accomplished. Mr. T. Parker, of Wolverhampton, had provided electrical plant for colliery purposes. Electrical motors, no larger than a lady's muff, could work at 2 H.P., and no energy was wasted while work was not being done. Messrs. Siemens, of London, had saved 3,000 tons of coal a year by the substitution of electrical wires and motors for belting and shafting; and much labour had been saved in addition. Some years ago he (Prof. Thompson) suggested that a motor house should be established at Soho, or Clerkenwell, London, for the benefit of the large number of small manufacturers there who required only a little power, and that not constantly. At present each one has to meet the cost of maintaining his own steam engine or gas engine; but under the plan suggested each would have a small electrical motor, connected with the generating station by wires. He would then take only as much energy as he actually required, and there would be no waste.

In concluding, Prof. Thompson spoke of the advance of electrical traction in the United States and the Colonies. The use of horse-power on the world's tramways had greatly declined between 1890 and 1897, the mileage being reduced from 5,000 to 900, while the mileage of electric tramways had increased from 1,262 to 13,000. The province of Ontario had 900 miles of electric tramways—more than in the whole of Europe. In New Jersey one could travel 40 miles at a stretch by electric trams. In many American cities the workers were now able to reside in the suburbs, slum dwellings had declined, and the health, comfort, and morals of the people had improved. Electrical energy was being transmitted from the Falls of Niagara to the neighbouring manufacturing towns, to the great benefit of those towns; and Rome was now lit by electricity, the energy being conveyed from the Tivoli Falls. He looked forward to the time when electricity would warm our houses and be the chief motive power.

Prof. Thompson, subsequent to the lecture, was present at a supper in his honour given by the members of the society, and in reply to the toast of his health, the President said that we in this country were several years behind America in respect to electric lighting, but we benefited by being behind. The Americans had been too anxious to make use of their inventions, and had spent money like water on miniature schemes. We had started later, and had had full benefit of later experiment and research. In America many of the earlier enterprises were not paying, while in England nearly all our electrical companies were in a sound financial condition, and paying a good, and in some cases, a splendid dividend. Electric lighting companies were, indeed, among the best forms of investment. Mr. Chamberlain was responsible for an Act of Parliament which had retarded enterprise of this character; but this retardment had been most profitable, for it had prevented great waste of money in wild-cat speculation in the execution of miniature schemes, and in the laying down of large quantities of imperfectly designed plant. We had waited and had begun on a sound and substantial basis. In Boston, U.S.A., three sets of machinery of electric lighting had been successively laid down, showing that it was possible to pay too dearly for progress.

THE SENTINEL CIRCUIT-BREAKERS.

The automatic circuit-breakers which are being introduced by the Sentinel Electric Company, of Wilmington, Del., depend for their action upon a principle which is claimed to be not only novel, but extremely effective and reliable.

The actual disruption of the circuit is accomplished by the destruction of a brittle metal bar which is included in the circuit, and which is provided with grooves to localise and insure the break.

The illustrations herewith show the single pole style of a type which, in its several sizes, is designed to protect electric light services of from 6 to 200 amperes at any voltage up to 250, and which is said to be adapted to alternating and direct current circuits with an equal degree of efficiency.

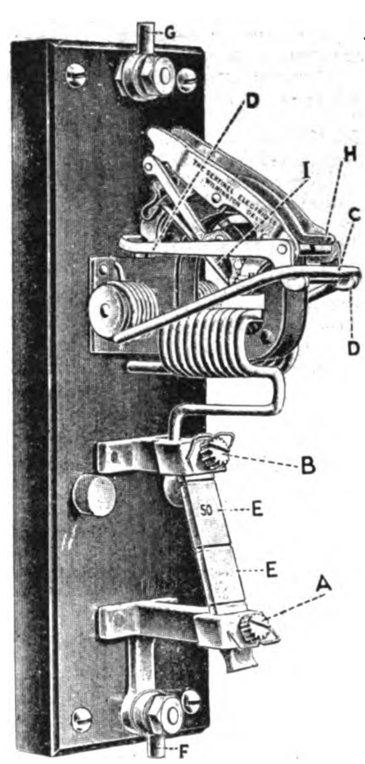

Fig. 1.—Sentinel Circuit-Breaker Set.

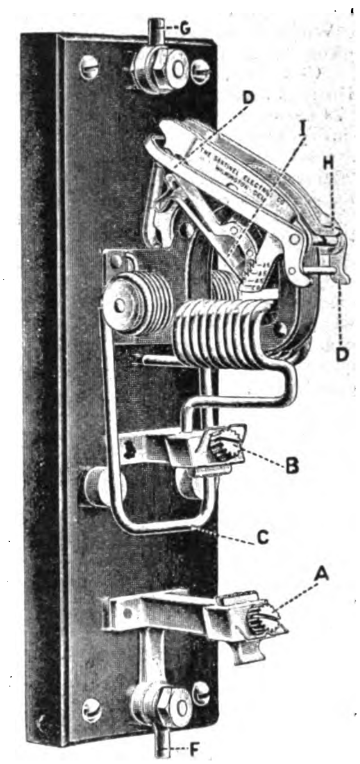

Fig. 2.—Sentinel Circuit-Breaker Discharged.

Referring to the accompanying illustrations, the breaking bar E E, fig. 1, is, upon the discharge of the circuit-breaker, struck and broken by the hammer spring C, as shown in fig. 2. When setting the device, with the upper mechanism D D, as shown in fig. 2, the operator raises the spring C, until it encounters and lifts the trigger H, when the lever D D will fall and leave the hammer spring set. A new breaking bar E E is then inserted after the stubs of the old bar have been removed.

Some of the advantages and important features which are claimed and guaranteed for this device are: (1) An annual inspection is all that the circuit-breakers require. (2) A perfect electrical connection is insured each time the device is recharged by the necessary insertion of the new bar. (3) Owing to their low ohmic resistance and the fact that they introduce no appreciable "lag" on alternating current, fuses may be replaced with no appreciable increase in the total losses. (4) The mechanical design of the device is such that vibrations do not affect it in any way, and once "set" it will remain so indefinitely unless the discharging point is purposely altered.

When the circuit-breakers are employed to protect light services, it is claimed that they perform successfully the functions of both a switch and circuit-breaker, as the circuit may, in all cases, be closed by the insertion of a new bar and opened either by removing the bar or by discharging the hammer spring by hand, thereby destroying it. This feature is especially valuable in the case of a serious short circuit or ground on the service wiring. According to present practice, the operator upon finding a protective device "blown" is required to open the switch controlling the service; he then recharges the device and closes the circuit by closing the service switch. Under similar circumstances the Sentinel circuit-breakers merely require that the spring C be set, the old bar stubs removed by loosening the screws A and B, and a new bar M M inserted. If the abnormal load is still "on" the bar will be broken by the hammer spring the instant the former touches the upper bar holder, and such an action is accomplished without danger of injury to the operator.

A combined switch and circuit-breaker also involving the breakable-strip principle, but adapted especially to the protection of motors, has been perfected by this company, and performs in a novel and efficient manner the functions of both devices.

MOTOR-DRIVEN PRINTING PRESSES.*

As was to have been expected, printers have not been the last to avail themselves of the advantages which recent discoveries by the students of electric science have placed at the disposition of industrial enterprise.

The advantage is obvious of a system which renders it possible to locate presses and other printing machinery in any part of an establishment, exclusive of line shafting, and also to run any one press at any time independent of the others. With presses equipped with direct-connected motors, each can be run at any hour of the day or night, with an expense of power proportionate to the work done, instead of that requisite for running a boiler, engine and heavy friction load of shafting and belting.

What such a saving amounts to may be judged by an estimate made by Prof. Benjamin, of the Case School of Applied Science, of Cleveland, Ohio. In 16 establishments whose plants Prof. Benjamin tested, there was developed 1,808 horse-power, and of this 979 horse-power, or 51 per cent., was expended in driving the shafts, pulleys and countershafts, while all the machines were idle. There are cases on record in which the loss of power in transmission from engines to machines, through belts, is much higher even than this, ranging from 80 to 93 per cent. of the total power generated.

So direct an appeal to economy as is made by such facts as these has a strong tendency to increase the already rapid process of installation of electric power plants.

Another great advantage of direct-connected motor to the press or other machine is that an accident to the power does not affect the whole plant, as the breaking of a belt or the main shaft causes a complete shut-down until repaired. And this by no means infrequent occurrence very often assumes the proportions of a real catastrophe.

NEW PATENTS.

[*Compiled expressly for this journal by* W. P. Thompson & Co., *Electrical Patent Agents,* 322, *High Holborn, London, W.C., to whom all inquiries should be addressed.*]

3,645. "Arrangement for transmitting telegraphic messages in contrary directions simultaneously over a single wire." M. Bernstein, proprietor of the firm of J. F. Wallman & Co. Dated February 14th. (*Complete.*)

3,695. "Improvements in magnetic circuits or parts of circuits.' E. Wilson. Dated February 14th.

3,731. "Transmitting drawings, pictures, sketches, and the like by telegraph or telephone." J. M. Martin. Dated February 15th.

3,749. "A method of oxidation and bleaching by means of electrolysis." J. G. A. Rhodin. Dated February 15th.

3,783. "A new or improved method of and apparatus for generating electricity." C. O. Barrows and C. H. Smith. Dated February 15th.

3,796. "Improved means for displacing, dispersing, or extinguishing arcs formed in breaking electrical circuits." S. H. Short. Dated February 15th. (*Complete.*)

3,805. "Improvements in electrical switch apparatus." T. H. Minshall. Dated February 15th.

3,806. "Improvements in apparatus for making and breaking electric circuits at predetermined times." H. O. Swoboda. Dated February 15th.

3,808. "Improvements in impedance coils for enclosed arc lamps." G. Thomas-Davies. Dated February 15th.

3,827. "Improvements in blocks and electros and surfaces for printing from." G. T. Teasdale-Buckell. Dated February 16th.

3,838. "Improvements in electric accumulators." A. Webb. Dated February 16th.

3,841. "Improvements in the method of and means employed for connecting electric glow lamps to main conductors." F. Palm. Dated February 16th. (*Complete*)

3,850. "Improvements in holders for electric glow lamps." W. Giepel, F. M. T. Lange and W. R. Saltrick. Dated February 16th.

3,902. "Improvements in devices for protecting electric incandescent lamps from the action of moisture." H. Beau and M. Bertrand-Taillet. Dated February 16th.

3,905. "Improvements in suspension devices for electric and other lamps." P. G. Pasquet. Dated February 16th.

3,924. "Improved fastening for the heads of electric glow lamps." J. Kremenezky. Dated February 16th.

3,925. "Improvements in electric safety fuses and lamp connections." H. C. Gover and J. M. Moffat. Dated February 16th. (*Complete.*)

3,960. "Improvements in electric switches." J. Williams and W. M. Walters. Dated February 17th.

3,993. "Improvements in, or relating to, electric ignition devices for internal combustion engines." A. J. Boult. (La Société Nouvelle des Etablissements Decauville Aine, France.) Dated February 17th. (*Complete.*)

4,002. "A new and improved telephone support and an automatic circuit controller." L. Duque. Dated February 17th.

4,004. "Improvements in switches for altering the speed and direction of revolution of electric motors, and for altering the course of the electrical current round field magnets." W. R. Edwards and S. F. Beevor. Dated February 17th.

4,046. "Improvements in, or connected with, the distribution of electricity on the three-wire system with the neutral wire at earth potential." A. B. Blackburn, W. L. Spence and E. S. W. Moore. Dated February 17th.

4,075. "Improvements in methods and apparatus for electrothermally treating materials, more particularly for the manufacture of calcium carbide and other carbides, and the reduction of ores." H. Maxim. Dated February 18th.

4,114. "Improvements in telegraphic apparatus." F. W. Golby. (B. Fidler, Austria.) Dated February 18th.

4,121. "Improvements in telephones, telegraphs, and other forms of electrical signalling." E. Wilson and H. Godsal. Dated February 18th.

4,150. "Improvements in electrical accumulators or storage batteries." T. W. Allan and Allan & Adamson, Limited. Dated February 19th.

4,176. "Improvements in the distribution of electricity over electric railways." M. Cattori. Dated February 19th. (*Complete.*)

4,202. "Improvements relating to the displayal of words or devices by electrical illumination." W. J. H. Jones. Dated February 19th.

ELECTRICAL PATENTS OF 1884, EXPIRING IN MARCH, 1898.

We are informed by Messrs. W. P. Thompson & Co. that about 85 applications for electrical patents were filed in the month of March, 1884. Out of these some were never completed, and of those that were, only one has been allowed to run its full length of term, viz., 14 years, and being of interest we give a small abstract below:—

4,828. "Improvements in telegraph posts." J. Oppenheimer. Dated March 13th, 1884. Relates of the construction of forming telegraph posts of metal tubes of various oval sections. Thus strength and lightness are secured, and the attachments have no tendency to turn round the post.

CONTENTS:

THE ELECTRICAL REVIEW.

Published every FRIDAY, Price 4d.

The Oldest Weekly Electrical Paper. Established 1872.

TO BE OBTAINED BY ORDER FROM ANY NEWSAGENT IN TOWN OR COUNTRY.

OFFICE:—4 LUDGATE HILL, LONDON.

Telegraphic Address: "AGEEKAY, LONDON." Code A B C.

Telephone No. 988 Holborn.

ALL Letters should be addressed to the Proprietors, H. Alabaster, Gatehouse & Co.

ADVERTISEMENT RATES ON APPLICATION.

The "Electrical Review" is the recognised medium of the Electrical Trades.

SUBSCRIPTION RATES.—In *Great Britain*, Post Free per Year, 19s. 6d. To all other countries, per Year, £1 4s.

BINDING.—Subscribers' numbers bound, including case, for 4s. each volume.

CASES.—Cloth Cases for Binding can be had, price 2s. 6d. each.

READING CASES, to hold from One to Twenty-six Numbers until the Volume is complete for Binding, can now be had from the Publishers, Price 6s. or Free by Post (in Great Britain), 6s. 6d.

FOREIGN AGENTS.—*New York*: D. VAN NOSTRAND, 23, Murray Street. *Paris*: VEUVE J. BOYVEAU, 22, Rue de la Banque. *Berlin*: ASHER & Co., 5, Unter den Linden.

Cheques and Postal Orders (on Chief Office, London) to be made payable to MR. H. ALABASTER, 4 Ludgate Hill E.C.

WEATHERPROOF WIRE.

THE subject of this article is not, as one might be led to suppose from the title, a wire insulated in such a manner as to be unaffected by exposure to the weather, and, therefore, equally good under all kinds of atmospheric conditions; but it is the wire covered with a painted braiding which is so commonly used for overhead circuits in America, and which has been christened "weatherproof" by some humourist, probably because the one absolutely certain characteristic of all such wires is that they are none of them proof against weather. In reply to an article in which the use of these wires was condemned, Mr. Alex. Dow has taken up the cudgels in its favour, and in the pages of an American contemporary, *Electrical Engineering*, gives reasons for his belief that these so-called weatherproof coverings have a value which warrants their use.

It is almost impossible for us, accustomed as we are to judge of such matters from the standpoint of what is necessary in our much-abused English climate, to imagine that any sane man would run circuits under the conditions named by Mr. Dow; and it is therefore interesting, as throwing light on the enormous difference of climatic conditions in the two countries, to learn the opinion of an American engineer who has had considerable experience of overhead lines, and who, although he states that in his opinion all high tension circuits are best underground, believes that overhead lines will continue for many years to come, and that with them will continue the use of the cheap weatherproof wire.

Now what are the conditions under which these wires are used? We are asked to picture to ourselves the overhead trunk lines of a central station, supplying, as is generally the case, alternating current at a pressure of 2,200 volts, and direct current for arc lighting at pressures up to 5,000 or 6,000 volts. We are told that this line will consist of poles 40 feet to 60 feet high, each having from four to eight arms, and carrying from 24 to 64 insulators and the same number of wires (in some cases this number may be increased to 100 or more) of which probably a third to a half are alive continuously during the 24 hours. We will complete the picture in Mr. Dow's own words: "Almost any day during dry weather there may be seen on the poles of such a trunk line workmen taking up slack, changing over, cutting, or taking down wires; or stringing new circuits or branches; and this work goes on while the adjoining circuits are alive—indeed, in many cases, the wires being handled also are alive. The work requires that the linesmen climb through and among the conductors. It is impossible that they should do this without touching conductors which are in use, and it is equally impossible in many cases to prevent the wire which is being manipulated from crossing or twisting around other wires on the same line. Under the conditions of the electric lighting business it is a very great convenience, and almost a necessity, that this work should go on without interruption of service dependent on wires strung on the same poles. With bare wires this would be impossible; with wires continuously covered with insulation no better than the common weatherproofing, it is entirely possible during fair weather, and it should never be attempted during bad weather."

To our English ideas, even though we may think that our own Board of Trade regulations are somewhat too stringent in some cases, it seems as though the engineer who set his linesmen to such work would be inviting an indictment for manslaughter; especially when we read in the same article that Mr. Dow recognises that the measured insulation of such lines would not be materially reduced if the wire were not covered, and that the best of the "weatherproof" wires will pass through a summer shower without breaking down, even though exposed to the full pressure by the crossing of adjacent conductors, but that a rain storm of three or four hours, inevitably means the breakdown of such a cross; and that the first rainy days of autumn may always be expected to produce a fair crop of burn outs and earths. That such operations as are described above, should be possible in any weather without great risk of injury to the linesmen seems inconceivable, especially as the braiding is by no means imperishable, and we are told that most of these weatherproof wires have to be renewed after four or five years; but, even allowing this, we would ask how it is possible to maintain such circuits in wet weather, and whether the objection to shutting down all the circuits, if there is a fault to repair or a branch to connect, does not in many cases lead line superintendents to allow linesmen to take the risk of working on the line at times, when owing to the weather, the covering of the wire cannot afford any appreciable protection.

Even allowing for the difference of conditions due to climate, we cannot but think that the risks incurred are far too great; and, although we fully recognise that there are many cases in which no electric circuits would be possible unless overhead construction were allowed, we do not consider that a trunk line of many circuits is a case in point, and we hope the time is not far distant when all such trunk lines will be put underground.

GAS MANTLES AND GLOW LAMP FILAMENTS.

In the New York *Electrical World* for January 22nd last, in the course of a leader, entitled "Electric Lighting and Gas," it is suggested that the efficiency of the glow lamp might be "enormously increased" by coating the present carbon filament, or incorporating with it, some of those oxides of the rare metals which are used in the manufacture of the Welsbach incandescent gas mantles.

This suggestion is made on the assumption that the light emitted from these oxides is solely due to their being raised to a high temperature; so that if, by any device, they could be coated on, or incorporated with, an electric incandescent lamp filament, the same sort of effect would be produced in a vacuum, as is produced when they are heated in the form of an open network mantle over a Bunsen burner.

As various experiments, and unsuccessful attempts in the direction indicated, have, however, sufficiently shown this assumption is far from representing the truth; for it is essential for the production of the incandescent effect that the oxides should be heated in the presence of oxygen.

If these oxides be heated in a platinum crucible, so that they are somewhat sheltered from the air, to a far higher temperature than can ever be attained with a plain Bunsen burner, no special incandescent effect will be produced.

Again, if a small piece of "mantle" on the end of a wire be placed *in* the hottest part of a Bunsen flame, it will not give out as much light as when held on the *outside* of the flame, just where it issues from the burner; a position in which, although the temperature must be comparatively low, the bit of mantle will be well supplied with air.

With the object of increasing this supply of fresh air in the ordinary mantle and burner arrangement, a chimney has lately been introduced, the lower part of which is perforated with rows of holes, through which a constant stream of air plays on to the mantle. The effect of this chimney is to very greatly increase the light, as compared with that obtained when an ordinary chimney is used. Whether the already sufficiently brief life of the mantle would be further shortened by this increase of brilliancy tests only can positively decide, but that such would be the case is certainly highly probable.

Pointing in the same direction, viz., to the necessity for air, there is the fact that the light from a Welsbach burner is sensibly diminished if the atmosphere in which it is burning is not fairly good.

Thus it would seem that there is little probability of any improvement in the glow lamp, as we know it, by the simple introduction into its filament of the oxides of the rare earths. And some far more radical change in its construction would be necessary before advantage could be taken of the peculiar incandescing properties of these bodies.

We must, therefore, look for improvement, rather in the use of some material for filaments which will stand, without rapid disintegration or breaking, a higher temperature than the carbon now employed.

But there is another direction in which, if any improvement could be brought about, it would greatly facilitate the successful use of lamps of a higher efficiency than those now usually employed; that is in steadiness of supply pressure.

At present the unfortunate lampmaker, who attempts to produce a lamp which will run at, say, 3 watts per candle, has to reckon with the fact that a supply pressure of nominally 100 volts may, for a hour or two during the evening, stand, or rather wobble, at anything between that figure and 109, or even 110 volts. So that, in practice, he is obliged to use a larger "factor of safety" in fixing the efficiency at which he makes his lamps, than would be necessary if he could depend on their being run ~~more~~ closely to the pressure for which they are designed.

Liverpool and its Electrical Engineer.—The City Council has agreed, on the recommendation of the Tramways Committee, that Mr. Arthur Bromley Holmes be appointed electrical engineer-in-chief for both the tramway service and for the electric lighting and other electrical purposes, on condition that he gave up private practice, and that his salary be increased by £600 per annum in lieu of his private practice, to be paid out of the tramway account.

ON SOME RECENT INVESTIGATIONS IN CONNECTION WITH THE ELECTRO-DEPOSITION OF METALS.*

BY J. C. GRAHAM.

(*Continued from page* 279.)

THE result was remarkable. It was seen at once that the current density could be raised far above anything now used, and that the surface of the copper was as bright and as smooth as it is when using such low densities as 100 amperes to the square metre. With this apparatus the current density could be made so great that, if the jet was shut off for a fraction of a second, the whole face of the cathode blackened almost instantaneously, although it remained quite bright as long as the jet was allowed to flow.

The next step was to measure the maximum possible current densities which could be used with this apparatus, consistently with obtaining the proper forms of deposit. It was, however, found that owing to the very rapid growth of tree-like formations of copper which took place all along the edges of the cathode, it was impossible to obtain even approximately accurate measurements of the current density. With such current densities as 2,000 to 3,000 amperes to the square metre these formations will grow to a length of 10 or 15 millimetres in a few minutes, attached at one end to the edge of the cathode, and waving about in the electrolyte like seaweed.

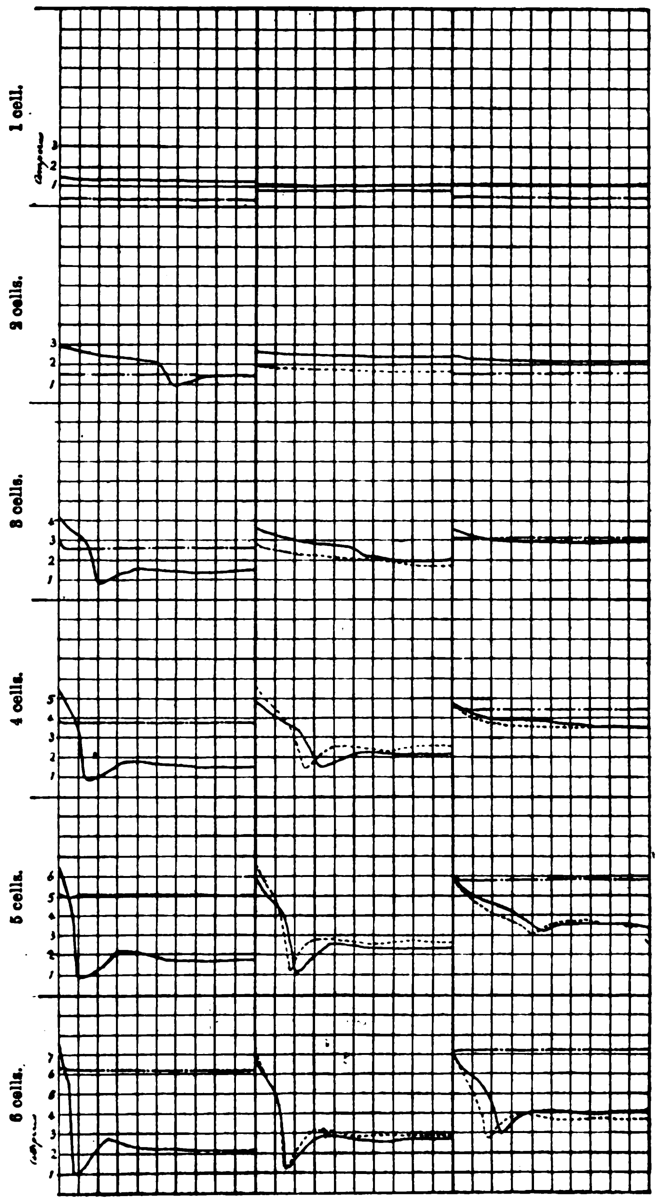
A great many unsuccessful devices were tried with the object of preventing these growths from forming, such as varnishing the edges of the cathode, dipping them in paraffin, covering the edges with thin strips of India-rubber, &c. But it was invariably noticed that the growths began along the line where the insulating material and the cathode met and gradually spread over the face of the insulator, holding on at one end to the cathode.

The cause of these growths appears to be the excessive crowding of the lines of force extending from the anode to the cathode, which takes place along the edges of the cathode, and which causes the current density along these edges to be far in excess of the current density over the rest of the face of the cathode; and acting upon this hypothesis, the difficulty was ultimately overcome by preventing this crowding by means of a shield, as shown by a split line in Diagram C, which was placed at a small distance from the face of the cathode, overlapping the edges, so as to preserve the free circulation of the electrolyte between the shield and the cathode, at the same time shielding the edges of the cathode from the lines of force which would have extended from the anode towards those edges. It is sufficient if the distance between the shield and the cathode is about 6 millimetres, and if the breadth of the shield be about 25 millimetres, so as to overlap the edge of the cathode by about 12 millimetres.

The only remaining uncertainty in determining the current density over the exposed face of the cathode, arose from the difficulty of determining what amount of the current passed under the shield. It was obviously inaccurate to assume that the whole current was passing into the area exposed by the shield, because some of it passed under it. It was found, however, by cutting the cathodes through the middle with shears, so as to get the thickness in section, that the amount of deposit under the shield was very small, and that if the cathode surface was assumed to be about 6 millimetres wider at each edge than the surface exposed by the shield, the results would be fairly accurate for experiments of this character.

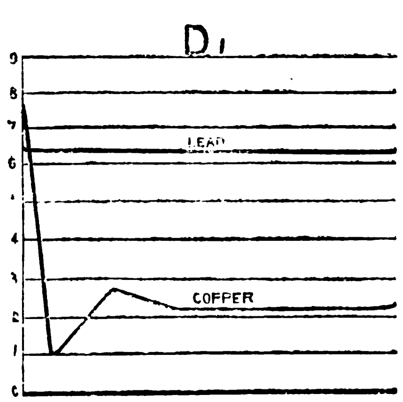
The actual current densities which it was found possible to use with this apparatus will be referred to later on, when all the conditions of accurate measurement have been referred to.

Down to this time copper anodes alone had been used, and although the current could be accurately measured, the readings in the various experiments differed so widely and corresponded so little to the various voltages used that it was obvious that some condition was present to which no attention had been paid; and it was found that this condition was the relation of the size of the copper anode to the number of amperes passing. It was found that if the current density measured on the face of the anode exceeded a certain amount



D.

the current density fell very rapidly after it was switched on, and remained far below what would have been expected according to the voltage.



In order to investigate this matter, a number of copper anodes of different sizes were made and tried at various voltages with a cathode which was the same size throughout.

The first anode was of the same area as the cathode; the the next one was double the area, the next three times the area, and so on, the last one being eight times the area of the cathode.

---

* Communicated to the Royal Society.

The cathode was a copper plate, of a square shape, measuring 50 millimetres along the sides, and in front of it was fixed a shield through which was cut a square hole measuring 30 millimetres along the sides.

A jet of about 6 millimetres diameter was used, the fall of the electrolyte being about a third of a metre.

A large number of observations were made with these anodes, each one being tested when connected with one cell, two cells, &c., up to six cells. The results are graphically represented in the Diagram D.

As the curves on this diagram are too small to be seen distinctly, the Diagram D_1 was prepared. It represents the bottom square of the first vertical column in D, considerably enlarged, and may be taken as an example of all the other squares.

Six cells were used, and the curved line, A B, shows how the current fell rapidly to the point, *c*, in about $1\frac{1}{2}$ minutes, then recovered rapidly, but only slightly at the point, *d*, and then became pretty constant. In this case the copper anode was the same size as the cathode.

(*To be continued.*)

ALUMINUM AS A RIVAL OF COPPER AND BRASS FOR ELECTRICAL CONDUCTORS.*

By ALFRED E. HUNT, S.B., President of the Pittsburg Reduction Company.

Copper has been used for electrical conductors very largely in the past, due to its comparatively high electrical conductivity, power of withstanding corrosion, ease of soldering and brazing, malleability, tensile strength and ductility. The exceptions in the past have been in telegraph wires of soft wrought-iron and the brass, iron, and steel used in the parts of electrical machinery.

Aluminum has already been used successfully for the purpose, and this article is written to call attention to its comparative merits as an electrical conductor.

The following facts regarding the metals, copper and aluminum, in bars, rods, and wire suitable for electrical conductors, need first to be considered.

Copper has a specific gravity of 8·93 (authority—Association of Copper Manufacturers of the United States, 1893); an electrical conductivity, when pure and soft annealed reckoned at 100 in the Matthiessen scale, but as ordinarily used in electrical conductors of about 98—97·61 (authority—Prof. W. C. Roberts-Austin); a tensile strength of from 16,500 lbs. per square inch in soft annealed pure copper (authority—Carnegie's Hand Book) to 65,000 lbs. per inch in hard-drawn bars; and a selling price of about 14 cents per pound in the United States, and an equivalent selling price of 130 marks per 100 kilograms in Germany, for wire, bars, and rods such as are used for electrical conductors.

Aluminum has a specific gravity of 2·68; an electrical conductivity (commercially pure metal) of 63·00 (authorities—Chas. F. Scott, of the Westinghouse Electric Company, and Prof. Jos. W. Richards, of Lehigh University); a tensile strength in pure soft wire of 26,000 lbs. per square inch, and in hard-drawn rods or wire of 40,000 lbs. per square inch.

Special selling price: The firm of Aron Hirsch & Son, of Halberstadt, Germany, are ready to sell aluminum conductors in the form of rods, bars, plates, and wire drawn to $2\frac{1}{2}$ millimetres in diameter, at the special low rate of 280 marks per 100 kilograms, for large quantities of metal, and similarly the Pittsburg Reduction Company will sell rods, bars, plates, and wire drawn down to No. 12 Brown & Sharpe gauge (eight-hundredths of an inch diameter) in large special orders for electrical conductors, at the rate of 29 cents per pound at their works in the United States.

These prices are special rates, below the regular prices for aluminum which these concerns have decided to make for electrical conductors alone, in order to favour the introduction of aluminum for this purpose and to overcome the handicap which aluminum has occasioned by its lower electrical conductivity than copper, in the matter of special low relative prices.

From these facts it is evident that:—

1. Any given volume of copper is $\frac{8\cdot93}{2\cdot68}$, or 3·332 times heavier than an equal volume of aluminum.

2. The equivalent price of 14 cents per pound for copper for any length of any equivalent section of aluminum wire or bar, would be 14 cents times the factor 3·332, or 46·65 cents per pound. That is, 1,000 feet of wire of, say, $\frac{1}{10}$th inch diameter, would cost equally as much if bought of copper at 14 cents per pound, or aluminum at 46·65 cents per pound. Aluminum, therefore, sold at 29 cents per lb. is only 62 per cent. of the cost of copper at 14 cents per pound section for section.

3. Reckoning the copper conductor to have its maximum of 100 per cent. conductivity, and the aluminum to have a conductivity of 63 per cent. (which the Pittsburg Reduction Company are ready to guarantee for their special pure aluminum metal for electrical conductors), then for an equivalent electrical conductivity a given section of copper that can be placed at 100 should be increased in area in round numbers to 160 to give an equal conductivity.

4. Due to their relative specific gravities, the weight of the given equal length of the aluminum conductor with 160 sectional area will be only 48 per cent. of the weight of the copper conductor with sectional area of 100, having the same electrical conductivity.

$100 \times 8\cdot93 = 893$, weight of the copper.

$160 \times 2\cdot68 = 428\cdot8$, weight of the aluminum.

$\frac{428\cdot8}{893} = 48$ per cent.

5. As to their relative cost for electrical conductors of equal conductivity, aluminum at 29 cents per pound is the most economical conductor as compared with copper at 14 cents per pound.

Taking, as an illustration, an aluminum conductor to replace a copper wire of No. 10 B. & S. gauge (about $\frac{1}{10}$th of an inch diameter), the aluminum wire of equal, in fact, somewhat superior, electrical conductivity would be of No. 8 B. & S. gauge (slightly over $\frac{1}{8}$th of an inch diameter).

The weight of a mile of No. 10 copper wire is 162·32 lbs., and its cost at 14 cents per pound would be equal to $22.72.

The weight of a mile of No. 8 aluminum wire would be 79·46 lbs., and at 29 cents per pound would cost $23.04.

Forty-eight per cent. of the weight of No. 10 copper wire, which will give equal electrical conductivity in aluminum wire, would only weigh 77·91 lbs.; so that, more accurately, $22.59 would be the cost of a mile of aluminum wire at 29 cents per pound to replace a mile of No. 10 copper wire at 14 cents per pound, costing $22.72.

6. The Continental requirements in tensile strength for soft copper wire, rods, and bars used as electrical conductors is 22 kilogrammes per square millimetre, the English requirement being similarly 14 tons per square inch; and our American requirement is about its equivalent of 32,000 lbs. per square inch.

Aluminum wire, rods, and bars will be furnished of 63 per cent. electrical conductivity, which will have an equal tensile strength per *unit of area* with the copper, and, therefore, with the electrical conductivity equivalent to 48 per cent. of the weight of the copper and sectional area of 160 against the area of the copper section 100, the tensile strength of the aluminum conductors will be as 100 for the copper is to 160 for the aluminum. This would mean, if a square inch of copper conductor was used of, say, 32,000 lbs. per square inch tensile strength, the equal conductivity area of 1·6 inches of aluminum would have a tensile strength of 51,200 lbs.

It has been already determined that with aerial lines, the snow and ice load is practically as heavy on lengths of small wire, as upon larger sections, so that no objection upon this score can probably be found to the use of the larger sections of aluminum wire.

Both on account of having only 48 per cent. of the weight, and on account of having about 60 per cent. more strength, the aluminum conductor could be used in much longer spans between supports, and the number of expensive poles and insulators can be materially diminished. Properly drawn aluminum wire is as tough, and will stand bending as severely without breaking, as soft copper wire. The toughness of aluminum wire is, however, greatly modified by the care and skill used in manufacture. If it is drawn too

* Advance proofs of this paper were courteously forwarded through the Secretary of the Institution of Electrical Engineers.

severely through the dies, or is not well annealed at the proper intervals in the drawing operation, it is finished much more brittle than when properly manipulated.

Hard-drawn copper wire, especially that in the smaller sections drawn through diamond dies, is furnished with a tensile strength of 65,000 lbs. per square inch. What the maximum tensile strength of the best pure hard-drawn aluminum will reach under similar favourable conditions for developing the maximum tensile results, has not yet been determined, but from experiments already made it can quite surely be predicted that at least 50,000 lbs. per square inch can be obtained, and, perhaps, even higher strength still.

Aluminum hardened with a few per cent. of alloying ingredients can be furnished in wire with a tensile strength far in excess of what can be obtained in pure aluminum. Experiments are now being made by the Pittsburg Reduction Company to determine just what alloy will furnish the maximum tensile strength, together with maximum electrical conductivity. From results already obtained, it can surely be predicted that an alloy of aluminum can be furnished which, drawn into wire, will have a tensile strength of at least 62,000 lbs. per square inch, and electrical conductivity of more than 50 in the Matthiessen scale. This material will rival hard-drawn copper wire and the silicon bronze materials which are now in use, where maximum tensile strength, together with good electrical conductivity, are required.

(To be continued.)

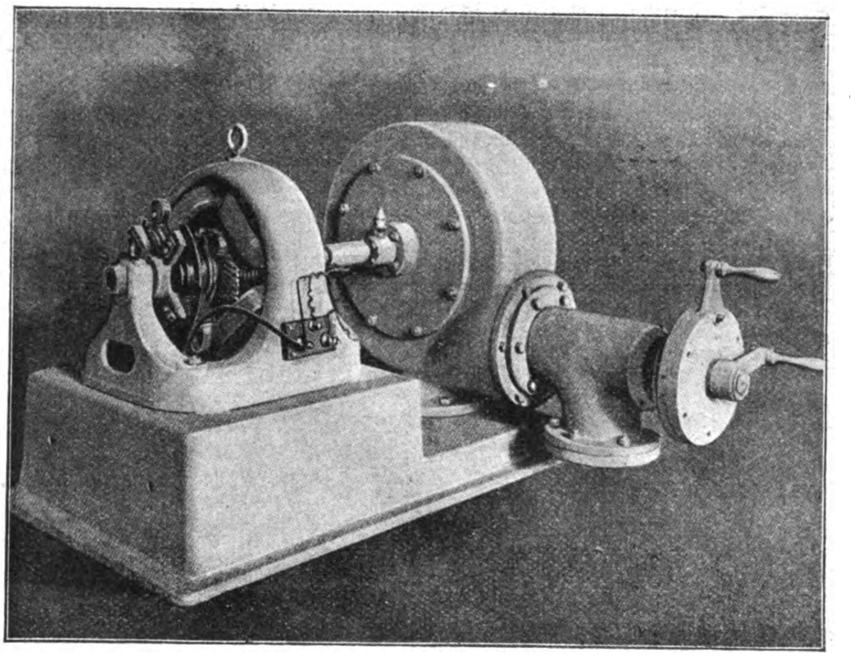
THE USE OF OIL IN STEAM BOILERS.

MUCH has been claimed for kerosene as a scale solvent in steam boilers. The use of this article is, however, strongly condemned by Mr. W. H. Edgar in a paper read to an American society. It is, perhaps, to the abundance of kerosene in America that its use in boilers is due. We believe less use has been made of it in England, but it may be well to regard the opinion of an American who must have seen a good deal of the effects. The effects of kerosene on scale are mechanical. It inserts itself between the scale and the plates and loosens the scale, but the oil is volatile, and passes off with the steam, and is very destructive of the joints in heating apparatus, and generally intensifies grooving and pitting. Further, it dilutes the lubricating oil in the cylinders of engines and generally exerts an oxidising effect on rings and piston rods, and with metallic packing it is difficult to keep this in order. Where the oil gets between the scale and the plate of the boiler it will carbonise by the heat, and, in doing so, will carbonise the iron, and this action will go on all over the boiler below water line. *In toto*, the use of kerosene is a mistake, and its scale-removing effects have been much overstated. The use of too pure a water should also be avoided in boilers, pure water being so general a solvent and requiring something to satisfy its solvent properties. Hence the pitting of boilers fed with pure water, which, however, is often only a name for water containing a little acid. For scale prevention the author asks for sugars and tannins only, not tannic acid, but tannin still combined and containing the inert matter, the sap, the sugar, and the starch. The object is to convert the carbonates of lime and magnesia in tannates. The tannin will not work on the sulphate of lime, but this and sulphate of magnesia will reduce to saccharates by the use of sugar, and these break up into oxalates, tartrates, and carbonates, and part of this goes to the tannin, and forms tannate of lime, and thus a small amount of sugar will serve as a carrier for a considerable reduction of sulphates to the final form of tannate. To sum up, Mr. Edgar advises to use no kerosene and no caustic soda, but a properly proportioned amount of tannin extracts, sugar and starch. Properly compounded there should be no action on the iron. The tannins will deal with the carbonates, and the sugars will deal with the sulphates, while the wood starch assists to prevent the sugars being too stable, and also the tannins, thereby securing easily convertible tannates and saccharates. It is a mistake to use much soda in compounding, say, starch and slippery elm, as the soda kills the gelatinous properties, and tannate of soda is produced which is not wanted. We might add that, where boiler compounds are used, they require feeding in minute quantities with the water, and are best mixed in a tank from which a small pump will put them all day through very dilute into the feed pump outlet or inlet.

LIGHTING A PUMPING STATION BY WATER-POWER.

THE following letter reproduced in the New York *Electrical Review* from the *American Machinist*, relates to a practice which is believed to be new and which has much to commend it. Its principle is the use of water from a steam pumping station as power-water for lighting the station. The economy of the plan over a separate small engine for driving the dynamo is obvious. If the water-wheel has an efficiency of 85 per cent., which can easily be reached in moderate sized wheels of the impulse type, the plan secures a coal economy, for lighting, of 85 per cent. of that obtained by the pumping engine, which latter, being of large size, and of high grade, gives a resulting economy far in excess of what could be secured by any small engine driving the dynamo direct.

The illustration herewith gives an excellent idea of the general arrangement. The handle shown at the top on the right of the illustration adjusts the nozzle to position and the handle below binds it there.



An index plate and pin insures the correct placing of the nozzles with respect to the wheel. The impulse type of wheel has peculiar advantages for this class of work, in which the speed of the wheel must be the same as that of the machine to be driven. With a turbine, a change in size ordinarily changes the power delivered as well as the speed, and it is only by chance that a standard turbine wheel can be found to fit any given case in both speed and power. With the impulse-wheel, on the other hand, the diameter can be varied at will without changing the power delivered, so long as the nozzle remains unchanged, and in proportioning wheels for this class of work it is only necessary, in ordinary cases, to make the wheel of such diameter that when running at the number of revolutions required by the machine to be driven it shall have a peripheral speed equal to that called for by the head of water under which it operates. James Leffel and Company state that the success of this plant has led to the installation of a similar one, but of about three times the capacity, at the Columbus, Ohio, waterworks. The letter is as follows:

"There has been no undertaking in my past experience that has given more satisfaction than this, and in fact it exceeds our expectations as to economy. As we were too far from the city electric plant to receive light from them, we concluded to put in a plant of our own, and purchased a 40-light machine—which will easily carry 50 lights—and connected it direct to a 12-inch Leffel Cascade wheel, which is connected to our main service pipe inside the station. The discharge is piped to pump-well to obviate any waste of water. Under 70 lbs. pressure—our minimum—we can run 80 lights, 16 candle-power, 110 volts, with $\frac{21}{32}$-inch jet, which gives a theoretical flow of 90 gallons per minute, making a total of 54,000 gallons in 10 hours' run, which actually cost 23 cents per 1,000 gallons for coal burned while pumping, as all other items, such as salaries, banking fires, &c., remain a constant, showing the exact cost to us of running 80 lights 10 hours to be 12·42 cents. Our coal costs us $1·75 per ton, delivered in shed at station. The data are based on my last year's report of the triple-expansion pumping engine.

"The Cascade motor has five different size jets—$\frac{5}{16}$-inch, $\frac{9}{16}$-inch, $\frac{21}{32}$-inch, $\frac{11}{16}$-inch and $\frac{23}{32}$-inch in diameter—made on the smooth taper plan. The nozzles are all in one brass disc, 4 inches thick, bored longitudinally, the disc being 5 inches in diameter. The jets are laid off on a circle having six spaces, one being left blank to close main opening when not in use. I enclose rough sketch to give a better idea.

"The generator is a multipolar, compound, shunt-wound machine, the speed being 890 turns per minute.

"W. C. Powell,

"Engineer Springfield, Ohio, Waterworks."

THE ELECTROLYSIS OF MAGNETIC SALTS.

Revue d'Electricité of February 12th prints an interesting article by Prof. Hurmezescu, of the University of Jassey, on the behaviour of iron in electrolytic cells placed in strong magnetic fields. Two principal observations are made: one that the rate of deposition and dissolution of iron electrodes

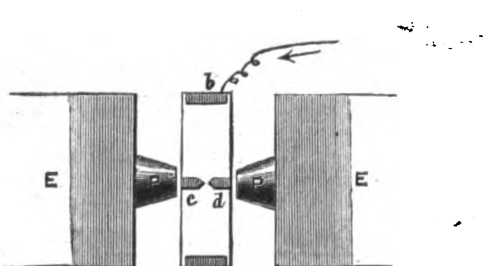


Fig. 1.

is greatly affected by the magnetisation of the iron; the other that electrolytes containing magnetic salts, placed in a magnetic field, show vortical movements, or eddies, when a current of electricity is passed through them.

A number of experiments are described, among which the following are perhaps the most striking. A solution of copper sulphate is poured into a shallow tray of thin sheet iron placed on the poles of a magnet. The iron is dissolved, and the copper deposited along lines, which are roughly at right angles to the field, and are described by the author as being approximately the lines of equal magnetisation. The appearance of the tray is figured in the paper. The arrangement of another experiment is shown in fig. 1. Here a b are iron electrodes placed in an electrolytic solution of the following composition:—

Water	1,000 grm.
Double sulphate of iron and ammonia...	100 "
Sulphate of soda	100 "
With glycerine to prevent oxidation of the iron salt.	

At c d are placed what the author terms parasitic electrodes, also of iron, nearly dividing the cell in half, and having sharp opposed edges. The electromagnet, P P, strongly magnetises c d, the intensity of magnetisation being more intense at the sharp edges than elsewhere. On passing a current through the cell iron is deposited on c d, opposite the anode, and dissolved opposed the cathode. The deposition of iron is found to be much greater on the highly magnetised edges of c d, than on the other parts.

In a third experiment the cell was arranged as shown in fig. 2, having two gaps left in the divided iron partition,

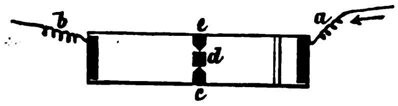

Fig. 2.

c, d, e, and a porous diaphragm across the anode to prevent diffusion of the oxygen. The electrolyte was of the same composition as before. On placing this cell in a magnetic field across c, c, and passing a current from a to b, the eddies shown in fig. 3 were observed. The speed of the eddies

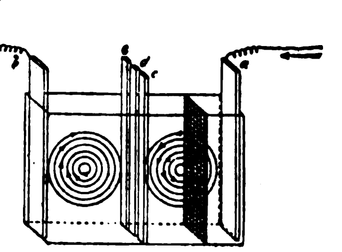

Fig. 3.

increased with the strength of the field, but did not occur at all with non-magnetic electrolytes. On replacing a, b, fig. 2, by copper electrodes, and the electrolyte by copper sulphate, c, d, e being, as before, of iron, no eddies were seen until the copper in the solution was partly replaced by iron from c, d, when slow eddies began to form.

The article is well illustrated with figures taken apparently from photographs. Before leaving this subject we may perhaps refer to an experiment shown some years ago to the present writer by a French electrician. A steel wire held

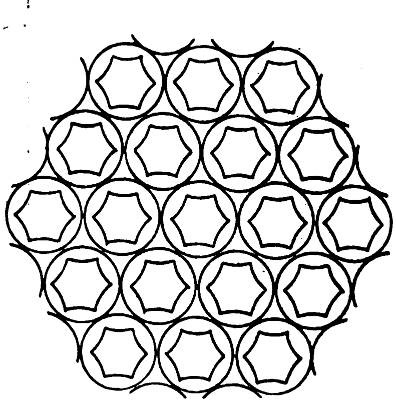

Fig. 4.

vertically in a solution of common salt and alum, forming an anode, is eaten away very smoothly and regularly into the form of a long tapering and very sharp point. It had been proposed to sharpen needles in this way by lowering them in bundles into the electrolyte, and passing a current through them as the anode. Under these circumstances, however, they did not form circular conical points, but pyramidal ones with hollow sides. The circles in fig. 4 represent the sections of the bundled needles before the action has begun, and the hexagons the sections of the taper points where electrolysis has removed parts of the material. Another proposal made was to use this property to maintain the sharp edges of rotating circular knives. These were to run in an electrolytic solution and a current of electricity constantly passed through them. The plan might have many applications in other directions.

COMPARING RESULTS OF TESTS ON ACCUMULATORS.

[COMMUNICATED.]

If the batteries or cells to be compared are of the lead and lead peroxide types, one of the safest, fairest and most correct comparisons is to give the watt-hours discharge per lb. of plates, at equal rates of discharge. It is still more correct if we take the watt-hours per lb. of positive plates at equal rates of discharge in amperes per lb. of said plates, taking the weights without connectors. The reason for this is, that by taking positives only, and all at same discharge rate per lb., the results are fairly correct when cells of different sizes are compared, whereas when cells of different sizes are compared by watt-hours per lb. of plates or per lb. of battery the results are altogether misleading, unless the cells are of same size, that is, have plates which give same rate of discharge per lb.

Reports made on tests of batteries, especially those made by supposed experts in teaching establishments, sometimes do not recognise the foregoing precautions, hence such reports for purposes of comparison are valueless as a rule.

Another rule which should be observed in making tests is, that the rate of discharge in watts ought to be maintained constant from start to finish of the discharge, few reports state whether this or any other rule was observed. Some tests are made with constant resistance in which the watts fall nearly 25 per cent. from start to finish. Others are made with a variable resistance maintaining constant ampere rate of discharge. Both these methods give a higher watt-hour capacity result than the method of testing at a constant rate of watts with a variable resistance.

That constant rate of watts is the correct method is undoubted, for if we use a battery for power or traction, it may be called upon to work at the same rate at the end of 6 or 8 hours as at the beginning of a run. In any case, however, it must be remembered that there are three methods, and the results obtained by one method is not comparable with the others; and again, unless a report states which method has been used it is not comparable. Following is a table of comparison as it should be:—

Name of cell.	Rate of discharge + watts per lb. constant.	Watt-hours capacity per lb. of positives.
A	5·5	32 8
B	5·5	21 8
C	5·7	19 0
D	4·5	26·6

In this table, A, B, results are strictly comparable, for the discharge rate is same in both.

Although C gives 19 watt-hours against B 21, C is probably the best battery, as the rate of discharge of C is much higher. D, again, gives 26.6 at a rate of 4·5, but is probably not much better than B, if the rate had been raised to 5 watts discharge per lb. of positive.

These figures are results actually obtained on tests on small cells, and they are quite comparable with results on large cells.

An examination of the best and most used cells in the market proves that all of them run at about 5 watt-hours rate of discharge per lb. of positives, and at that rate give a capacity of 25 watt-hours per lb. of positive plates.

These figures refer to everyday working batteries, and cells giving these results when made up into batteries give 8 to 9 watt-hours per lb. of battery, it is obvious that this result is one which depends much, on the boxes used, also on the nature of the connectors, and also on the amount of acid solution used. The amount of acid solution can be reduced to a very much smaller quantity than was formerly considered necessary. In good traction cells 61 watt-hours per lb. of acid solution can be got easily in large cells; this is a very remarkable fact and one which is very significant from an electro-chemical point of view.

From these figures, *i.e.*, the rate of discharge in watts per lb. of positives and the discharge in watt-hours per lb. and the watt-hours per lb. of acid, the watt-hours per lb. of any cell or battery can be calculated approximately from tests made on one positive only, thus reducing the testing of batteries from a clumsy rule of thumb state to an almost exact science.

The antiquated expert cannot, from observed results on one plate, calculate results for 11 or 13 plates; there are so many things he does not know, that he does not make the attempt.

Up till recently the accumulator has been pretty much where the dynamo was before the application of the doctrine of the magnetic circuit was applied. It will be strange, indeed, if such an important electrical apparatus cannot be reduced to exact science.

Improvements have been made by trial and error, but much greater improvements are possible, when exact knowledge is obtained regarding the proportions and proper consistency of the elements, and the exact knowledge of the chemical and electro-chemical reactions involved must be elucidated.

THE TESTING OF INSULATORS FOR HIGH TENSION SERVICE.

In a recent issue of the *Electrical World* Mr. J. R. Haskin gives some interesting and useful information with reference to testing of insulators for high tension power service. Unless each insulator is thoroughly capable of withstanding the pressure and strain to which it is to be subjected when in service, there will necessarily be one or more unknown weak spots, which, by their breaking down, will necessitate the discontinuance of service until, after more or less trouble and delay, the particular location of the trouble is found. Too much attention therefore cannot be paid to the thorough testing of the insulators before installing them.

When the Niagara-Buffalo transmission line was about to be constructed, the question of insulation received very careful attention from the electrical superintendent of the company, Mr. Paul M. Lincoln, who after careful deliberation designed for the purpose two transformers, each capable of producing a pressure of 20,000 volts.

The insulators to be tested were placed in an inverted position in a square iron pan capable of holding a dozen or more; the pin holes were filled up half full with salt water, and the insulators were also submerged in the same to within about an inch of the edge of the outer petticoat. One lead from the transformers was attached to the pan and the other to a short bar of zinc or copper, this being placed in the pin hole of each insulator in turn.

During the early tests a pressure of 20,000 volts was first applied, and if the insulator stood this test the pressure was gradually increased to 40,000 volts, but after the first few had been tested it became customary to apply the entire 40,000 volts pressure at once. If the insulator is satisfactory, nothing will be noticed except a subdued humming sound, caused partly by the transformer and partly by the discharges due to a condenser action on the surface of the insulator, with oft times a snapping blue, static spark jumping from the edges of the pin hole to the outer petticoat edge of the insulator, this latter phenomenon generally appearing when the surface of the insulator is at all moist, or has upon its surface a few drops of the salt water accidentally spilled upon it. But if there is a slight flaw in the make-up of the insulator a yellowish spark will immediately manifest itself, and if the breakdown is at all serious this spark may be seen coming through the top surface of the inverted translator, below the level of the brine.

Experiment showed that when fresh water was used instead of brine, a much larger proportion of the insulators passed the test, and were apparently sound and well made. It is rather difficult to say why this should be, but the fact remained nevertheless.

The reason for the poor insulating properties of defective insulators was easily made apparent by breaking up one of the insulators and examining the porcelain, which was found by the application of red ink to an unglazed surface to be very porous. In nearly every case also, flaws caused by imperfect kneading of the clay were found, poor lots of insulators being often filled with these imperfections, while only one or two flaws would be found in the imperfect ones from a lot which gave a high percentage of satisfactory insulators. Too much importance cannot be given to this matter, as it is above all the prime requisite of a porcelain insulator. A perfect piece of porcelain, $\frac{3}{16}$ths of an inch in thickness, is for all practical purposes non-puncturable.

The necessary size of the insulator to be used appears to vary somewhat according to the climatic conditions of the locality in which they are to be installed. The writer has been informed that in certain sections in the West where the climate is very dry and the air thin, power has been and is now being transmitted at a pressure of 50,000 and 60,000 volts on wires insulated only by the ordinary glass insulator in common use by the telegraph and telephone companies. In such a locality as Niagara Falls this would be impossible, as the moisture and dust collecting on the surface of the insulator would be sufficient to allow the current to leak across even when but 10,000 or 15,000 volts were being used. Therefore, a large insulator made of the first quality of porcelain, well baked and vitrified, is the only one that will stand the pressure and wear of a high tension transmission line in such a locality.

No better proof of the satisfactory nature of the test described can be given than the working of the overhead system of the Buffalo transmission line since the commencement of its operation. Except for a few cases of breakdown among the insulators that had been installed temporarily, it has been necessary to remove only two or three insulators out of the whole set of more than 12,000.

STANDARD CLAUSES FOR SPECIFICATIONS.

We have received a circular, with a copy of certain agreed standard clauses, from the Electrical Engineering Plant Manufacturers' Association and the Municipal Electrical Association, which has reference to a point on which we recently commented, namely, the relation of customer, engineer, and manufacturer. The circular refers to the feeling that has been found to prevail, that the regulations which commonly govern building contracts are unsatisfactory when applied to electrical contracts. Manufacturers have felt that they are at the mercy of the purchaser's engineer, and engineers have felt that they are called upon to exercise judicial functions not strictly appertaining to their duties. The attention directed upon the subject has led to the above associations taking the matter in hand for discussion, and with a view to agreement upon a model specification. The clauses agreed to we publish in full further on, so as to make them as widely known as possible. So far only commercial conditions have been dealt with, but it is hoped that there will be standardising of more technical features, whereby a purchaser will be able to buy better and cheaper goods at an earlier delivery than where new patterns are called for, as well as being able to avoid the inevitable risks of new patterns. Perhaps there is no more unpleasant portion of an engineer's duties than the enforcing upon a contractor of requirements in respect of entirely new work of the engineer's own design. There is always ample room for dispute, and even in respect of the business clauses of a specification, there is room for dispute as to the true meaning and intent. With standard clauses there would very soon be arrived at a general consensus of opinion as to what each clause really signified, and many loopholes now open for shirking on the one hand, and perhaps unfair demands on the other, would be closed. This is a much to be desired blessing. Engineers should be glad to be relieved of the judicial functions imposed upon them in specifications, functions for which neither their position entitles them fairly to exercise, nor their training fits them. The clauses now published bear upon a number of points on which there has been much friction, and it is proposed to add to them as occasion offers, until a complete specification is available to cover all essential contingencies of electrical contracts.

Undoubtedly there should be an effort to standardise technical features, and especially the testing requirements of specifications. Such standardising might be subject to periodical revision, and this could very easily be arranged as knowledge advanced. To standardise is not necessarily to crystallise: it is rather to direct men's minds upon details and conditions, so that much thought is directed in a concentrated manner in a given direction, in order that improvements may be made by concentrated thought that are now not made by the system for diffuse energy. We hope to return to this subject at an early date.

The Electrical Engineering Plant Manufacturers' Association and The Municipal Electrical Association.

Approved Standard Clauses.

For adoption among the General Conditions of Specifications for Electrical Engineering Plant.

Drawings.—The contractor shall, at his own expense, supply to the purchaser copies of the drawings necessary for the erection of the works under the contract, but shall not be called upon to furnish constructional details further than in the opinion of the engineer are required for the purposes of the contract. If the contractor shall be called upon to supply additional copies of the drawings, they shall be paid for at a fair price to be arranged. The engineer shall, in addition, have the right at all reasonable times to inspect any drawings of any portion of the plant contracted for at the works of the manufacturer.

Powers of Engineer to Reject Materials or vary Works.—The engineer may from time to time during the execution of the contract, vary, increase, or reduce the contract works, and may order any work or portion of work executed, or partially executed, to be removed or altered; and the difference of cost occasioned by any variation, addition, omission, removal, or alteration, as aforesaid, shall be added to or deducted from the contract price as the case may require, and the amount of such difference shall be ascertained and determined in accordance with the rates specified in the schedule of prices set out in the schedule to the contract so far as the same may be applicable, and where the same are not applicable, then according to such rates or prices as shall be fair and reasonable; such prices in cases of dispute shall be referred to arbitration as herein provided. No addition shall, however, be made to the contract price in respect of any such variation of, or addition to, the said works, unless the instructions for the same shall have been given by the engineer in writing, nor unless such instruction shall state that the matter thereof is to be the subject of an extra charge.

A decision of the engineer to reject materials, or require workmanship which is in his opinion defective, to be amended, shall be obeyed by the contractor. If the contractor shall so desire, and of such desire shall give notice in writing to the purchaser within 72 hours after receiving notice from the engineer, the question involved in any such decision of the engineer may be submitted to arbitration, as herein provided. The contractor shall not, under these circumstances, cease to proceed with the execution of the contract, to the prejudice of the purchaser.

Date of Completion of Works and Penalties.—The contractor shall within a period of from the date of the order of the engineer to commence the contract works (and time shall in this respect be of the essence of the contract) complete the whole of the contract works, and make good all damage done to the roads, buildings, or other property of the purchaser and fill up all holes, and trenches which may have been dug, and level any mounds or heaps of earth that may have been made, and reinstate all works, property, matters, and things disturbed or damaged, and deliver up to the purchaser the said works complete to the satisfaction of the engineer; and in case the contractor shall make default in performing and observing the provisions of this clause within the period hereinbefore limited or within any extension of the same period which may be granted under the powers herein contained, the contractors shall and will pay to the purchaser on demand as ascertained and liquidated damages, and not as a penalty, the sum of £ * for each and every week which shall elapse between the expiration of the period limited by this clause or any extension thereof which may be granted as aforesaid, and the actual performance and

* N.B.—Under no circumstances to exceed 1 per cent. per week of the contract value.

observance by the contractor of the provisions of this clause, unless the execution of the contract works shall have been delayed by an unreasonable strike of workmen, by excessive inclement weather affecting the work of the contractor, or by any circumstances over which the contractor shall have had no control; provided that no such damages shall accrue as payable by the contractor to the purchaser after the time when the plant is complete and ready to be set to work.

Power of Purchaser to use Works during Execution.—The purchaser shall have power to use any portion of the plant reasonably capable of use at any time during execution of the contract, and also pending any arbitration. In such case, however, the contractor shall be entitled to receive, by way of rental, a sum equal to 5 per centum per annum upon the amount withheld in respect of any machinery put into beneficial use, and not paid for.

Payments.—During the progress of the works, and as soon as possible after the expiration of each month, the contractor shall be entitled to payment, on the engineer's certificate, of 75 per cent. of the value of the work executed on the site and plant delivered on the site during the month, until the balance of 25 per cent. of the value of the executed work retained by the purchaser is equal to 10 per cent. of the total value of the contract. Thereafter the contractor shall be entitled to monthly payments as before equal to 90 per cent. of the value of the remainder of the executed work, until the contract works are completed for continuous effective usage by the purchaser, whereupon he shall become entitled to one-half of the retention monies. The remaining half of the retention monies shall be payable * months later.

The purchaser shall, however, be entitled to retain such sum of money as, in the opinion of the engineer, fairly represents the prejudice to the purchaser arising out of incomplete or defective details, until the adjustment of such details to the satisfaction of the engineer.

In cases where the contractor, although willing so to do, is unable to repair defects in certain parts of the contract works in consequence of the purchaser not being able to place such parts into his hands for the requisite time, owing to their being in use, the contractor shall be paid in full for such portion of the contract works on giving an undertaking, with security to the satisfaction of the purchaser if required, to remedy the defects so soon as the same can be placed in his hands for the purpose.

Certificates of Engineer.—The engineer shall, from time to time, issue his certificates in accordance with the clause relating to payments, and payment shall be made to the contractor at the earliest possible date. Certificates of the engineer, other than the final certificate, shall not be considered conclusive evidence as to the sufficiency of any work or materials to which they relate, nor shall they relieve the contractor from his liability to make good all defects as provided by the contract. The contractor, when applying for a certificate shall, if required, furnish to the engineer an approximate statement of the value of the work executed and materials delivered, based on the original estimate.

When the contract works shall be completed, as referred to in the clause relating to payments, the contractor shall be entitled to call upon the engineer for a certificate to that effect. In case of the refusal of the engineer to grant such certificate when called upon by the contractor so to do, this refusal shall be subject to appeal under the Arbitration Clause herein contained.

Maintenance and Limitation of Responsibility of Contractor.—The contractor shall be responsible for, and shall effectually maintain and uphold in good and substantial condition, in accordance with the specification, fair wear and tear only excepted, all and every part of the contract works for a period of months † from the date of completion of the contract as certified by the engineer.

Arbitration.—In case any dispute or difference shall arise between the purchaser, or his engineer on his behalf, and the contractor, either during the progress of the works, or after the determination abandonment, or breach of the contract, as to the construction of the contract, or as to the reasonableness of any extra charge, or as to the withholding by the engineer of any certificate to which the contractor may claim to be entitled, then either party may, within 72 hours, but not later, give to the other notice in writing of the existence of such dispute or difference, and such dispute or difference may be referred to arbitration, which arbitration shall be deemed to be a submission to arbitration, within the meaning of the Arbitration Act, 1889.

Approved on behalf of the Electrical Engineering Plant Manufacturers' Association.

CORRESPONDENCE.

Knots.

In the account of the meeting of the T.C.M.C. in the Electrical Review, of the 4th inst., Admiral Sir A. Hoskins is reported to have said that the company were manufacturing a cable "60 knots in length," and that their new cable steamer would have a speed of "12 knots per hour."

I submit that such phrases are inexact and wholly unscientific, and their employment by the chief of a large company, which earns its money by applied science, most improper. The use of these phrases are a sure and certain indication of a neglected professional education. Hence they are in daily use by masters and officers of cable and mail steamers, pilots and seamen generally of the merchant service, also by naval officers of the pre Royal Naval College period. Needless to say, laymen, such as yachtsmen, shipowners, newspaper writers, Members of Parliament, and even judges and barristers of the Admiralty Court offend in the same way, but, of course, they may be pardoned.

In the Royal Navy and in the Staff College one never hears such expressions. I, however (dare I say it), have even known cable engineers and electricians guilty of this offence. *They* ought to know better.

For the edification of the gallant Admiral and of others who may feel disposed to stick to their knots as well as to their guns, permit me to say what a knot is. A knot is a speed, and a knot is the unit of nautical speed; it is the product of a length 6,080 feet into a unit of time 1 hour. It is not in itself a length, but the word is used to denote an interval (a length) between one or more marks on the log line, which instrument is a *speed* measurer. In this sense only can knot be regarded as a length, and in this sense only is it employed by Lord Kelvin in his "Navigation." According to Prof. Greenhill, F.R.S., who I need hardly say is an authority on dynamics, a "knot per hour" is an acceleration; hence a steamer going "20 knots per hour" would make the passage between Liverpool and New York in something like 17·3 hours. Prof. Cotterill, F.R.S., and M. Slade, R.N., in their "Mechanics" say, "the expression (knots per hour) is erroneous, and should be guarded against." I am sorry to say that a length of so many knots and knots per hour are tacitly acquiesced in by cable engineers and electricians. I did manage to convert one cable man, but I fear he has through evil communication lapsed from the narrow path of accurate definition. I also converted a shipmaster, but his employer did not grasp the subtle distinction between knots and knots per hour. Why not use the word "naut" to denote a length of one sea mile as proposed by Lord Kelvin? then the knot would be a speed of one naut per hour.

Geo. Herbert Little,
Master Mariner, late Student Royal Naval College.

Re Salaries of Assistant Electrical Engineers.

Having followed with great interest and sympathy the recent protests in your columns against the absurdly low salaries paid to assistant electrical engineers, I should like to point out that your correspondent "Fiat Justitia" is saddling the wrong horse when he places the entire onus of this case of sweating on the borough councillors. Surely Mr. Boot has enough influence with his committee to place his staff in a somewhat better position if he tried, and could ensure at least those men who do the work, for which he takes all the credit, and probably a salary as large or larger than the combined salaries of all his staff, at least a "living wage."

Also, I think it must have escaped the notice of Mr. L. D. Collins that the advertisement in question was for an *experienced* man, thus prohibiting anybody taking this job for the sake of experience.

By the bye, would Mr. Collins be so kind as to give the derivation and meaning of "horse-sense." I have not yet been able to find anybody capable of furnishing me with this information.

Tom.

D

Electrical Driving of Cotton Mills.

I am glad to see you are taking interest in the correspondence now going on in *Engineering* on the electrical driving of cotton mills.

This subject is of immense importance to the electrical industry, because if this scheme can be shown to be feasible and profitable, every cotton mill will take as many units per annum as *an average provincial town*, and the demand for motors and dynamos will exceed anything that we have hitherto experienced. Your interest, and that of your friends, lies entirely with the progressives, but to make Fortune smile you must tickle her; you have not tickled her much yet.

For instance, your contributor says, "Nevertheless he (Mr. Herschmann) is sceptical of Mr. Raworth's 15 per cent. for electricity"—of course, I quite expected you to say "on this head Mr. Raworth is all right, and even if he had said 14 or 13 or even 12 per cent. loss between indicated and electrical horse-power, many of our friends would have been quite ready to accept orders on his specification." You know these facts quite as well as I do, probably better.

Now take the cotton mill engine—it averages 500 to 1,200 H.P. indicated—quite a good-sized engine, but not much of an engine for economy; it could not compete with an engine of 6,000 H.P., fitted with modern appliances and giving a H.P. for 1 lb. of coal.

Again consider the motors, they are now too high in speed for the spinner's frames, but these latter have been designed to suit the speed of line shafts, they can be modified considerably for electric driving; how much, it is impossible to foretell, but when we remember that the speed of the spindles is from 7,000 to 9,000 revolutions per minute, it is apparent that the speed difficulty is not likely to be insuperable.

Your contributor says "a cotton mill is *not* a large cube." Now, this is either a misprint or your contributor has never seen a cotton mill; he is, however, quite right in pointing out that the power required for driving a cotton mill is almost entirely absorbed in friction, much less than 1 per cent. is put into the cotton—this is where we come in; not only does electricity transmit power with less friction than iron and leather, but it uses neither oil nor laces, it has no cogs to crack, no ropes to ravel, no belts to break—it is always ready and always willing.

It is an open question whether the application of electricity will not permit of sufficient saving being made in the cost of the machines to pay for the motors, if it should do so, the question is settled—the genius of Lancashire has not yet been directed to this problem, but whenever it may take it in hand it will solve it.

A "mule," for example, is a factory in itself, it contains a book full of mechanical motions, and he would be a bold man who would say off-hand that electricity will not simplify some of them and reduce the friction of the internal driving gear.

Mr. Herschmann's figures of ¼ to ¾ H.P. per machine are very misleading, they apply only to the card room, whereas the bulk of the power is absorbed in spinning and doubling in, which processes a single frame will absorb from 4 to 10 H.P.

Mr. Herschmann considers it a defect that the power is not intermittent, but electrical engineers will not grumble at that, it is just what they hanker after, to me it opens up the possibility of supplying electrical energy at something less than a halfpenny per unit, at which price electricity would take the first place as an angel to redeem mankind from the incidental curses of jerry built civilisation.

John S. Raworth.

Dublin Cables.

With reference to the letter from Mr. Ruddle, the superintendent of the Dublin Electricity Works, which was published in your last issue, it may be well to state that, of the cables supplied to the Dublin Corporation by this company, a considerable portion was delivered in 1892, and was used, we understand, in the high tension alternating incandescent lamp circuits. Of these cables, we believe, no complaint is made. Faults, however, have occurred in the arc lighting circuits, the cables for which were supplied since 1893; the conductors of the latter are 7/16s, the thickness of the dielectric being 1/13". In no case were these cables laid underground by this company.

Through the courtesy of Mr. Ruddle the cables were examined by us in April of last year. As the result of our examination we found that at the junction boxes the cables were seriously damaged, and that even where a breakdown had not yet occurred, we found in some cases the cables to have been punctured or wounded; we therefore submit that this does not point to faulty material, but rather gives evidence of mechanical injury, for which a manufacturer should not be considered responsible.

As regards the cable, apart from these faults the rubber appeared to be in very good order; a length returned to our works for examination was tested with 5,000 volts alternating current, and showed no signs of weakness. Under these circumstances it cannot with justice be held that a dielectric of India-rubber fails in its object, and calls for the substitution of some other material, which in addition to its own inherent defects would be subject to the same mechanical disadvantages. The trouble, in our opinion, lies in the handling of the cables, and the want of complete understanding between the manufacturers and the contractor, or persons to whom the work of laying is confided. Whether or not other manufacturers may be better able to establish such an understanding, we are unable to state, but we may assure you that we spare no pains to place at the disposal of the contractors for laying, such knowledge as we possess on the subject.

Wm. Gray,

Electric Light Department, The India-Rubber, Gutta-Percha, and Telegraph Works Company, Limited.

"Is the Nervous System a Coherer?"

In the Electrical Review, of March 4th, there appears a very interesting notice of a communication made by M. Branly to the Académie des Sciences, on December 27th, in which some striking analogies are pointed out between coherer action and the conductivity of the nerves for nervous currents. That this is not the first time such a suggestion has been made will appear by the following extract from an article by me, headed "Apologia pro electricitate jus," in the *Lancet*, of May 4th, 1895:—"It seems conceivable that other histological arrangements, *e.g.*, those nerve fibrils which conduct, yet only touch and do not anastomose, those motor nerve endings which are only in contact with the sarcous substance; indeed, any conducting arrangement in the animal body which may be classed as a 'bad contact'—may constitute the physiological analogue of what would be electrically known as a 'coherer.'"

W. S. Hedley, M.D.

March 6th, 1898.

Cost of Long-Running Plant.

The letter of your correspondent, "Atlas," raises an interesting question. Along with the engineer to the South Staffordshire scheme, the writer had occasion to go very thoroughly into the question of the probable generating costs, and, from the mass of information which we collected, it was perfectly evident that with ordinary good luck the project could be made to pay very well with customers paying at the rate of 1d. a unit and discounts. In the case of Niagara, it should be remembered that a town had practically to be built at short notice, in order to create a demand for power, but in South Staffordshire the town, or rather towns, with their multitudinous industries, already exist, and if only the various representative bodies can be got to pull in one direction, a few more years will undoubtedly see energy being distributed over the area bounded by Wolverhampton and Birmingham, Walsall and Dudley at under a 1d. per unit.

At the St. Helen's Chemical Works where the generators are comparatively small (300 kw.) and, moreover, driven in the old fashioned way from slow running horizontal engines, the writer has it on good authority that the total cost of generation, including fair amounts for rates and taxes, interest and depreciation is nearer a ¼d. than a ½d. per unit. The load is, of course, a 24-hour one.

The Manchester central station, which has a very considerable day load, due partly to motors and also, no doubt to the peculiar atmospheric conditions of that salubrious place, is at the present moment generating current at a figure well under 1½d. per unit, and this is with the coal bill at the comparatively high (considering the position of the district) figure of ·4d. per unit (coal at Edinburgh is ·31d. and at Leeds ·25d.). At the present time the plant is some 30 per cent. overloaded, and all repairs, &c., have to be carried out during the night by men paid time and half, and those who know anything of night work will recognise how it "plays the bear" with the cost sheets. Mr. Day, the engineer in charge, stated to the writer that when they got the load well in hand (two 1,500 kilowatts are on order from the Electric Construction Company, Limited, and Siemens Bros. & Co.), and these extras were stopped, he quite expected the generating costs to drop well below 1d. per unit.

E. Kilburn Scott.

CORRESPONDENCE.—We have received, too late for insertion in this issue, a communication from Mr. A. J. Liversedge on "The Burning Question." This letter, and a reply thereto, will appear in our next issue.—EDS. ELEC. REV.

Appointment Vacant.—An electrical and mechanical working engineer is wanted to take charge of electric lighting and motor plant, &c., of a large works near Manchester. Applications have to be lodged with the Committee, Co-operative Wholesale Society, Limited, 1, Balloon Street, Manchester, by 14th inst.

Bankruptcy Proceedings.—At last Wednesday's sitting of the London Bankruptcy Court, John Dewhurst, 52, North End Road, West Kensington, electrician and sanitary engineer, was allowed to pass his public examination upon accounts showing total liabilities £860 (unsecured £390), and assets £196. He stated that he had traded as an electrician for 13 years, and he attributed his insolvency mainly to having paid an excessive amount to buy out a former partner in the sanitary engineer's branch. His failure was further caused by loss through embezzlement of money by a traveller, and by depreciation in the value of his stock-in-trade.

The British Thomson-Houston Company, Limited.—This company announces that owing to increased business, it has become necessary to take further premises at 26 and 27, Bush Lane, Cannon Street, E.C., where new showrooms have been opened. This address is now the head-quarters of the supply department, under the management of Mr. A. J. Ireland, as heretofore.

The "Cabinet Maker."—A copy of the *Cabinet Maker and Art Furnisher* (edited by Mr. J. Williams Benn) for March, is before us, and is a trade publication of the first class. There is much artistic talent bestowed upon electric light fittings and their arrangement in house and mansion lighting, and in this work the art furnisher and the electric lighting man have a kindred interest. There is plenty of room for the two trades to work together in the matter of electric light casings and mouldings, so as to prevent them becoming an eyesore. The work of Messrs. J. F. & G. Harris in this line is made the subject of a short article. Matter of interest is afforded by the article describing the new factory of Messrs. C. & R. Light, at Finsbury, the wood-working machinery in which is operated by electric power, a 30 H.P. electric motor being employed. A 20 H.P. motor is shortly to be added. An electric lift is used, and the building is lighted electrically.

Cole, Marchent & Morley.—This firm, of Prospect Foundry, Bradford, has just issued a new catalogue of steam engines and condensing plant. The list is got up in what we are accustomed to consider the American style of arrangement, with small pages and very neat illustrations. In the letterpress we observe a discussion of the points affecting the selection of a suitable type of engine for the required purpose, the question of space, character of load, water and fuel supply, and boiler pressure, being dealt with. Among those described is the Corliss engine, the firm's own standard Corliss engine, details being given of general arrangement, and of the construction of the principal parts, also Corliss engines with positively driven valves, high-speed vertical engines, and the steam Barring engine with automatic throw-out gear. One section to which we referred last week, is devoted to independent condensing plants. We understand that Messrs. Cole, Marchent & Morley have, during the past few years, practically remodelled their works, and laid themselves out for the production of the highest class of engineering work.

Crompton & Co., Limited.—This company have decided to close the office at 35, Queen Victoria Street, at which address they have hitherto been carrying on the sale of electrical cooking and heating appliances, and from March 1st this branch of their business will be carried on at the Arc Works, Chelmsford. In future they will supply their electrical heating and cooking appliances to the trade only.

Diversified Uses for Storage Batteries.—Our New York namesake recently gave a list of some of the battery contracts being carried out by the Electric Storage Battery Company, as signifying the diversified uses to which secondary batteries may be put. The latest contracts cover batteries to be used in connection with electric elevators; large plants for the Chicago Edison Company and the Buffalo Railway Company, and for private residences. Also in Mr. Howard Gould's new steam yacht *Niagara*, and Mr. Lloyd Phœnix's yacht *Intrepid*. The American Fire Insurance Company's building in Philadelphia is being equipped with a battery for night lighting. The Germantown, Pa., Hospital, is increasing the capacity of its plant by 50 per cent. Batteries have been furnished to the Cleveland Telephone Company and the Southern Bell Telephone Company; also for fire-alarm work at Portland, Ore., Augusta, Ga., and St. Paul, Minn.; for telegraph work on the Lehigh Valley Railroad, the Southern Pipe Line Company, the Great North-western Telegraph Company, the Chicago, Milwaukee and St. Paul Railway Company, the Postal Telegraph and Cable Company, and the General Electric Company. The Patton Motor Company and the National Electric Car Lighting Company are installing them in connection with their systems, and the State School of Mines, Colorado, has equipped its laboratory with them.

Dortmund Electrical Exhibition.—Arrangements are in hand for the holding of an electrical exhibition at Dortmund, Germany, in July next.

Electric Timepieces.—The Swansea Free Library Committee has had under consideration the tender of Mr. Gans for the supply of six electric timepieces for the library and one for the exterior of the building, at a cost of £84 14s. The matter was deferred.

A Gas Chairman on Incandescent Gas.—A shareholder in the Cheltenham Gas Company raised the question of street lighting at the meeting of the company held on Tuesday last week. He said there was a strong desire outside the area of the electric light for an improved illumination by gas. Many people were of opinion that an improvement could be made by the adoption of the incandescent burner. He hoped to have an assurance that the directors would consider this matter, make experiments, and give the Corporation the opportunity of judging whether a better light could not be supplied, and at what cost. The contrast between the electric light and gas light was so unfavourable to gas, that the Town Council were justified in asking for something better than was now given. Unless the lighting of the streets by gas was greatly improved, the lighting of them by electric light would make speedy strides. The speaker was differed from by another shareholder as to the result of the use of the incandescent burners in Liverpool. He had seen the lighting of the front of St. George's Hall in that city, and he came to the conclusion that it was an utter failure. The chairman, in reply, said the directors would only be too delighted to improve the lighting of the streets by any means in their power, and at several meetings lately they had considered the merits of incandescent and other burners; but the incandescent burner was not at present a perfect light, and certainly was not adapted for street lighting. Far from having the slightest prejudice to the incandescent burner, they would be glad to adopt it when they found it to be quite satisfactory.

List.—The British Bundy Company, of 100c, Queen Victoria Street, E.C., sends us a list of the Bundy time recorder. It is claimed that this system will tell the exact time each workman arrives at and departs from the works, even to the time devoted in the department where employed. The process of registering can be performed so quickly that no loss of time is entailed thereby. Each employé is given a numbered key, and upon arrival in the morning, whenever he goes out and returns during the day, and upon leaving at night, he registers the time and his number by inserting the key in the proper place in the recorder and giving it a quarter turn. In registering when going out, the lever at the left of the clock is held down, thereby printing a star opposite the number, showing departing time. A printed impression is thus made on the paper ribbon inside the clock of the hour and minute that each employé registers, together with his number. The recorders can be placed at convenient points at entrances or in departments. At each registration a bell rings.

"Lithin."—This is the name of a new insulating material being supplied by the firm of Hirschmann & Co., of Rummelsburg, b. Berlin, a German list of which is before us.

Motor Omnibuses.—Negotiations are in progress to start a service of motor omnibuses. Daimler petrol engines, of from 8 to 10 horse-power would be employed.

New Company.—The Compagnie d'Electricité Thomson-Houston de la Mediterranée, recently formed in Brussels, has a capital of £200,000. Its operations are restricted to Egypt, Greece, Spain, Portugal and Italy.

Rochefort-sur-Mer Exhibition.—We are informed that the buildings and other operations in connection with this exhibition are progressing. The exhibition is under the esteemed patronage of MM. les Ministres du Commerce, de l'Industrie, de la Marine et des Colonies, du Department, de la Municipalité et de la Chambre de Commerce. It will be both international and colonial, and will embody all the products of commerce, industry, marine and fine arts. Applications to be addressed to the Administration de l'Exposition, Mairie de Rochefort-sur-Mer.

The "Sans Pareil" Reflector.—Messrs. Webster and Co., Theatre Royal, Leeds, have sent us particulars of their "Sans Pareil" reflector, for diffusing the light of incandescent lamps. The reflector is of cardboard, lined with foil, which can be had in various colours, thus, to a certain extent, minimising the loss of light from colouring the lamps. Some of the reflectors which we have seen had been in use since July last, and had not tarnished, as is the case with metal and silvered reflectors. There should be a large demand for them in the smaller theatres throughout the country. Messrs. Webster have also patented an arrangement of battens made of bamboo to take the place of the cumbrous and heavy battens hitherto in use. The proprietor of the Theatre Royal, Leeds, speaks highly of both reflectors and battens.

The Shannon Water-power Scheme.—The scheme of the Shannon Electric Power Syndicate, which proposes to utilise water-power from the Shannon, is being pushed forward. A committee of the Limerick Fishery Conservators is to confer with the syndicate on the matter.

South African Notes.—Our contemporary, the *British and South African Export Gazette* for March, has the following notes on electrical work:—An electric lighting installation is under contemplation for the Monastery diamond mine, Orange Free State. An electrical tram installation is in contemplation at the Sheba gold mine, to replace the present steam tram. The provision of an electric light installation for Woodstock, Cape Colony, is under consideration by the Town Council. A dynamo for the electric lighting equipment of the Glen Deep mine has been ordered. The proposed electric lighting plant for East London will include 43 2,000-C.P. arc lamps, 327 32-C.P. glow lamps, 2,304 16 C.P. glow lamps, five continuous current machines for arc lighting, three direct coupling alternators for the glow lamp service, two switchboards, and other accessory material. Tenders ranging from £12,000 to £30,000 have been received by the Bloemfontein (Orange Free State) Town Council for the proposed electric lighting installation in that town.

Winding-up Petition.—A petition, presented by Mrs. Jones and Messrs. Ross, creditors, for the winding up of the Ariel Arc Lamp Syndicate, is to be heard by Mr. Justice Wright on March 16th.

ELECTRIC LIGHTING NOTES.

Acton.—The Council last week considered the electric lighting question in committee, interviewing Mr. Lacey and Mr. Trentham, the two experts who have been engaged to report.

Bath.—At the last meeting of the Electric Lighting Committee a statement was presented of accounts in connection with the Electric Lighting Works for the year 1897, from January 17th to December 31st, which showed the following figures amongst others:—Revenue account: Public lighting, £2,184 11s.; other consumers, £4,115 14s. 5d.; meter and transformer rents, £219 1s. 9d.—total, £6,519 7s. 2d.; repairs, £395 2s. 8d., stores on hand and sundry receipts, £358 11s. 4d.; total income, £7,273 1s. 2d; total expenditure, £5,001 8s. 9d.; gross profit, £2,271 12s. 5d.; special expenditure, £1,626 7s. 4d.; net profit, £645 5s. 1d. As regarded the income the first three items of receipts for current amounted to £6,519 17s. 2d., as compared with £6,332 15s. 8d. received by the company for 1896, showing an apparent increase of £186 11s. 6d. The actual increase, however, was much greater if they took into account the shortening of the year by seven days at its commencement, and, this adjusted, the increase was about £330. The following is a summary of the capital expenditure to December: Original purchase, £24,830 18s. 5d.; additions since—sundries, £1,168 2s. 7d; builder's contract, £6,175; further works sanctioned, £19,676 16s. 8d.; total, £51,850 17s. 8d. The profit was £1,952 7s. 5d., which it was proposed to deal with as follows: Interest on loans, £707 2s. 4d.; depreciation fund, in view of sinking fund, £600; balance carried forward to next year, £645 5s. 1d.

In respect of the complaints *re* the efficiency of the light, Alderman Taylor reports to the Council that night after night his colleagues and himself had been round making the necessary tests. In nearly every instance they had found that where there was a bad light it was not their fault, and did not arise from the works. The power supplied was quite equal to the demand. He hoped people were not going to throw on the committee the blame when the lamps were not properly cleansed. He was making a report.

Bedford.—Consumers are dissatisfied with the charges for current, and a meeting was held in the Town Hall last Friday, when it was considered that the charge should be reduced to 4½d. per unit.

Belfast.—The Engineer has reported the alternative arrangements he had proposed to the Acme Gas Company for the purchase of the engines at present on hire from them, and it has been decided to return the engines to the owners.

The Gas and Police Committee is taking steps to secure the best method of lighting the leading thoroughfares within the present area of the city.

Bromley.—The Bromley Urban District Council has received the information required by them from the Bromley Electric Lighting Company, and have finally decided to transfer the electric lighting powers to the company. The Council's seal has been affixed to the deed of transfer of the electric lighting powers to a company.

Bury.—At the last Town Council meeting Mr. Pickup stated that after allowing a sufficient reserve for the electric lighting plant, they were able to supply current at the rate of 180 units per hour, whilst the demand at present is for only 90 units per hour.

Calcutta.—The Bengal Government has nominated Mr. Mearn for the appointment of Inspector of Electric Lighting in the City of Calcutta.

Camberwell.—It is stated that the General Purposes Committee of the Camberwell Vestry, intend to repeat their recommendation to purchase the vested interests of the County of London and Brush Provincial Electric Lighting Company in that parish, at a premium of 33 per cent. upon the capital expended, with an additional dividend of 5 per cent.

Canterbury.—The Council has accepted Mr. A. J. Brewster's tender for the erection of their electric light station as follows: Buildings, £4,032; boiler seatings, flues, &c., £910.

Cardiff.—The electrical engineer (Mr. Appelbee) has submitted a proposed scale of reduced charges. The present rate is 6d. for the first two hours' average daily use and 3½d. afterwards. The new rate suggested was 7d. for the first hour and 3½d. afterwards, while in the case of that small class of consumers who only use the light on an average one hour a day the charge should be a uniform one of 5d. per unit. The supply of electricity for 1897 had increased by 34,000 units over the preceding year, the total revenue was £6,968, and the surplus on the year's working would probably be about £230. The chairman advocated a slightly further reduction by making it 3d. instead of 3½d. after the first hour. Consideration of the question was deferred to a future meeting.

Chelsea.—The Vestry will oppose the Bills to be introduced into Parliament by the Chelsea Electricity Supply Company and the Metropolitan Electric Supply Company.

Croydon.—At the last County Council meeting it was reported that the plans and quantities for the extension of the electric light station buildings were nearing completion, but as the matter was urgent the borough engineer had been consulted and had obtained prices for excavation and for putting in the foundations to the ground level and the engine beds. A tender had been accepted for the work. The mains are to be extended in Addiscombe Road at a cost of £200. 15 alternating arc lamps are to be employed for the lighting of South End.

Darlington.—Prof. Kennedy was last week appointed by the Council to report and estimate *re* electric lighting for the borough.

Dartford.—The District Council does not approve Mr. H. S. McKrell's proposal to apply for a provisional order. A municipal order is already applied for.

Dorking.—A public meeting was called by the District Council and held on Thursday last week, for the purpose of giving information to ratepayers on electric lighting, previous to their voting on the question. Mr. Warden-Stevens was present and gave, in reply to a question, figures of the progress made in other towns. He recommended the alternating current high tension system. He also recommended a municipal supply. Mr. Gripper, managing director of Edmundson's Limited, was also present, and he contended for the low tension system.

Dundee.—Some of the electric arc lamps for street lighting were lighted for the first time on 1st inst.

East Grinstead.—At the next meeting of the District Council, Mr. Steer will move a resolution in favour of making application to the Board of Trade for a license or provisional order to enable the Council to supply electricity for public and private purposes within their district, or such other area as the Council may determine. This was done at the request of the General Purposes Committee, of which Mr. Steer is chairman.

East London (South Africa).—Specifications and plans are about being prepared for the electric lighting and tramway scheme for East London. The Borough Engineer's report suggests supplying the present public and private requirements of the town and furnishing the Harbour and Railway Departments with supply. The *British and South African Export Gazette* says that the supply of electric energy for the tramways is also included in the scheme. The locality of the generating station has been fixed near to the new wharf extension and also to the railway line for coal supplies. The scheme makes provision for a reserved plant, spare or duplicate engines, dynamos, boilers, &c., being contemplated. For the incandescent street and private lighting service, two direct-coupled alternators, with one spare one, are recommended. For the arc lighting service, two continuous current machines are proposed, one being for the Harbour Board's requirements, and the other for the Railway Department and the streets jointly. For the tramway service, one continuous current machine is apportioned. A spare continuous current machine is to be provided, to be available for arc lighting or tramway, the switchboard being so arranged that the current can be used for either lighting or traction purposes. For lighting power the scheme contemplates an energy equal to 2,804 16-C.P. glow lamps and 43 arc lamps per hour, *plus* the energy required for the three miles of trams, or 18 B.T. units per hour. The lamp provision comprises—for street lighting, 18 2,000-C.P. nom. arc lamps and 300 32-C.P. glow lamps; for the Harbour Department, 21 2,000-C.P. nom. arc lamps and 725 16-C.P. glow lamps; for the Railway Department, four 2,000-C.P. nom. arc lamps and 27 32-C.P. glow lamps. For private lighting, 1,500 16-C.P. glow lamps are recommended. High tension mains would deliver the current to transformers for the service of the low tension mains supplying the street and private incandescent lamps. It is proposed to place the street lamps in duplicate, arranged so that the second is automatically lit when the first is extinguished. The tram track, three miles in length, passes through St. Peter's Road, Oxford Street, Fleet Street or Caxton Street, Currie Street, Inverleith Terrace to the Beach. Future extensions contemplate the crossing of the Buffalo bridge to the West Bank. It is proposed to adopt the overhead trolley system, the track being laid with 60-lb. rails, and the cars constructed to carry 25 persons. The Town Council appointed as expert Mr. Lewis Cousens, M.I.E.E., Johannesburg, to draw up specifications and plans for the Council's approval, upon which tenders will be called for.

Edinburgh.—Various proposals are under the consideration of the Cleaning and Lighting Committee for using electricity in many streets where gas is now employed.

Edmonton.—After inquiries made by the architect, in conjunction with a London electrical engineer, the Board of Guardians Electric Lighting Committee finds that the adoption of electricity instead of gas for lighting the Edmonton House will result in a considerable saving. The Committee has now been instructed to obtain plans, specifications, and estimates, with power to employ a consulting electrical engineer.

Glasgow.—The arc lighting of St. Andrew's Hall, which has not given satisfaction to the Council, was discussed again last week, and a resolution was passed, "that in view of the unsteady character of the lighting, of the noises emitted by the arc lamps, and of the fact that the roof is practically invisible under the present method, a system be adopted which will be both efficient and silent." The Bazaar Committee was already considering the matter.

Gloucester.—When the Council had electric lighting matters before it last week, it was resolved to purchase part of the Bearland estate for a site for the electric lighting and dust destructor works, at a cost of £7,125, instead of either of the sites previously suggested. The tenders, of which we gave details last week, were afterwards accepted.

Greenock.—The Sub-committee on Electric Lighting is recommending the Police Board to extend the electric light in town at a cost (including site) of about £28,000. The proposal provides for the erection of about 40 arc lamps and pillars along the main streets, and the extension of the installation should such a demand arise.

At a special meeting of the Police Board on 28th ult., held to consider the electric lighting question, it was agreed to ask the Board of Trade for another month's extension of time to allow of the matter being more carefully considered. Mr. Teague's supplementary report has not yet been submitted to the Board.

Hampstead.—In the estimates for the ensuing financial year just placed before the Vestry, show that it will be unnecessary to make any demand on the rates in respect of electric lighting. The income from private consumers for the year 1898-9 under this head is estimated at £19,000, and the expenditure, including working expenses, establishment charges, interest, and repayment of principal of loans, at £13,500, thus showing an estimated net profit for the year of £5,500.

The Lighting Committee has had under consideration the question of providing additional plant for the winters of 1898 and 1899, and the Vestry has decided that additional plant be obtained at an estimated cost of £17,000. Tenders will be invited for the supply of the plant. The new plant at present fixed is almost ready for working. Mains are to be extended along several roads.

Hartlepool.—The borough engineer is to report on the cost of laying down, in connection with a dust destructor, electrical plant for public lighting.

Islington.—At a recent Vestry meeting the treasurer, replying to a question, said the number of public gas lamps in 1892 was 4,548, and the cost of the gas for each lamp £2 17s. 9d. In 1897 the number was 4,725, and the cost of gas for each was £3 0s. 11d. In 1897 the number of public electric lamps was 100, and the cost of the current to each lamp was £40 6s. 1¾d.

Kingswood.—The question of the municipal purchase of the electric lighting undertaking of the Western Counties Electric Lighting Syndicate has been raised on many occasions, but up to the present has not been actually settled. The last meeting of the Kingswood Council had before it a letter from the syndicate asking when the purchase was likely to be completed. The chairman of the Council said that a letter was written to Messrs. Parfitt some time ago, stating that as soon as the Local Government Board inquiry took place and the loan was sanctioned, a time for settlement of the purchase could be arranged. Mr. Parfitt's list of the extension was received, and would come up at the inquiry. There is about 18 months of the lease with Messrs. Parfitt for lighting the district to run, during which period they have to keep the plant, &c., in repair.

Leeds.—The Parliamentary Committee has approved a draft of the provisional order to be asked for in connection with the purchase by the Corporation of the electric light undertaking. The following are the terms of the purchase proposed by the Town Clerk in a recent letter to the company. "(1) The purchase to take effect as from March 1st, beyond which date, of course, there could be no further expenditure by the undertakers upon the undertaking chargeable to capital account; (2) that the Corporation issue or transfer to the undertakers, as purchase money, Leeds Corporation Redeemable 2½ per cent. Stock in lieu of Irredeemable Stock, the former to be of such an amount as would equal in value in the market a Leeds Corporation Irredeemable 5 per cent. Stock; this amount or value to be determined by arbitration in case the parties differ; (3) should it be found that any sum is payable to the undertakers to make up the dividend on capital expenditure to 5 per cent., the Corporation will be prepared to pay that amount in cash. The like also in regard to any agreed expenditure on capital after the date mentioned; (4) that in order to save time in the completion of the purchase, the Corporation be permitted forthwith to investigate the company's books and accounts, with a view of ascertaining to their satisfaction the sum properly expended by the undertakers upon the undertaking and chargeable to capital account." The offer is made without prejudice to the application of the Corporation to the Local Government Board for a provisional order empowering them to issue Irredeemable or other stock for the purpose of the purchase, and subject to confirmation by the Parliamentary Committee and the Council.

Leyton.—The electrical engineer is to have provided a sub-station in High Road, Leytonstone.

Lincoln.—The City Council expects to start the electric light works in October next. The Electric Lighting Committee and the electrical engineer, Mr. C. Vesey Brown, are pushing the works forward. The City Council last week arranged the positions of a number of street lamps.

Liverpool.—The Lighting Committee has agreed to extend the electric supply mains into Manchester Street and School Lane. A new design of electric lamp is to be tried for Bold Street.

Manchester.—At the last City Council meeting, Sir John Harwood mentioned that the Waterworks Committe had requested Mr. Hill, C.E., to obtain the opinion of an electrical engineer and such other assistance as in his opinion might be necessary, and report as to whether the water supply from Longdendale could in any satisfactory way be utilised for the purpose of generating power in connection with the supply of electricity. There was, Sir John said, a difference of opinion on this subject, and they wanted to get at the facts. Mr. Alderman Higginbottom suggested that Mr. Wordingham, head of the Manchester Electrical Works, should be the engineer called in by Mr. Hill. Sir John Harwood said the suggestion was rather premature. No doubt Mr. Wordingham would be consulted.

The City Council has, on the recommendation of the Electrical Committee, advanced the salary of Mr. F. E. Hughes, secretary, from £225 to £250 per annum, and that of Mr. A. A. Day, chief assistant engineer, from £250 to £275 per annum.

Mardy.—On Thursday night last week the new electric lighting works put down by the Mardy Electric Light Company were opened. The plant was supplied by Messrs. Crompton & Co., and erected under the supervision of their local agent, Mr. Hughes. The plant has a capacity of 1,300 8-C.P. lamps, which is considered sufficient to light 2,000. The installation has cost about £1,600. The plant comprises a steel locomotive multi-tubular boiler generating steam at 150 lbs. pressure for a 60-brake H.P. compound vertical engine. There is a duplex feed pump capable of pumping 1,000 gallons per hour against the boiler pressure of 150 lbs. The Crompton dynamo is of the firm's latest patent shunt-wound type, having an output of 168 amperes at 220 volts when running at 750 r.p.m. A booster is used for raising the voltage to 300 for accumulator charging. At present about 600 lamps are supplied, but it is anticipated that very shortly the plant will be working at its full capacity. The Mardy Company is itself wiring and fitting consumers' premises. The fittings have been supplied by the Ediswan Company. Mr. Harris has been appointed electrician to the company. It is expected that the District Council will shortly go in for public street lighting by electricity. The price of gas is 4s. 6d. At a supper held after the inauguration ceremony there were various toasts proposed and responded to.

Newcastle.—It having been stated that the electric lighting works are to be removed from Pandon Dene to another spot, the question of purchase by the City Council has again arisen.

Nottingham.—At the new Empire Theatre of Varieties the electric light is largely used. In the auditorium alone there are over 100 lights; while for the footlights, lamps of various colours are employed. Mr. Joseph Blackburn carried out the electrical work.

Plymouth.—The Electric Lighting Committee intend to run the wires in the direction of the infirmary owing to the number of public and other buildings requiring the light. It is intended to wire buildings free of cost at first, and spread the payment over two years.

Poplar.—After a long discussion, the Board of Works has decided to undertake the electric lighting itself, without the intervention of the company that has been seeking a provisional order.

Reading.—The minutes of the Lighting Committee read as follows: On February 11th the Town Clerk was instructed to confer with the Board of Trade as to the powers of control of the Corporation with reference to changes proposed from time to time in the system of supply of the Reading Electric Supply Company, and the effect of such changes upon the question of the capital properly expended, which was to form the basis of the sum to be paid by the Corporation in the event of their purchasing the undertaking. On the 18th the Town Clerk reported that a further alteration of the system of supply was in contemplation, and it appeared to him the only mode in which the Corporation could exercise effective control over capital expenditure was by themselves becoming the undertakers under the order.

Saltburn.—The Cleveland and South Durham Assets Company proposes erecting plant, &c., for the supply of electricity to private and business premises, and a plan of the streets which will be traversed and crossed by overhead wires was submitted to the Saltburn Urban Council last week for approval. Mr. T. P. O. Yale, A.I.E.E., attended for the company. The Council will hold a special meeting to consider the scheme.

Sheffield.—The *London Gazette* of March 4th contains notice of the Bill to be applied for by the Corporation for the purpose of the purchase of the Electric Light Company's undertaking.

Shoreditch.—At the last Vestry meeting it was reported that the Lighting Committee had received from the makers of the engine a letter admitting their responsibility for not supplying relief valves to the cylinders, from which omission the Committee were advised the accident at the electricity works, recently referred to in the ELECTRICAL REVIEW, arose. After considering and being advised upon the circumstances, the Committee instructed the Vestry Clerk to write a letter to the company under whose contract the engine was supplied, informing them that owing to the non-supply of relief valves as promised by the contractor, they would be held responsible for the accident and any resulting damage to the works of the undertaking. The term of maintenance of this engine after completion for which the contractor is responsible has not expired. Postcards have been sent round to a number of consumers stating that unless the accounts were paid at once the supply would be cut off. These have given offence to many consumers.

Shoreham.—The Southern Cross Ship Yard and Engineering Company is to have an interview with the Urban Council *re* supplying the Shoreham district with electric light.

On Thursday last week the scheme was explained to the District Council. The total cost is estimated at £6,000, and this would provide 56 1,000-C.P. arcs, and 1,500 16-C.P. incandescents. Mr. R. E. Churchill-Shann explained the scheme. It does not yet seem to be settled whether it will be carried out as a municipal or a private undertaking. The matter is to be discussed in committee.

Southampton.—The Corporation is considering the subject of entering into an agreement with the Electric Free Wiring Company.

Stirling.—The Police Commissioners, last week considered the question of electric lighting in conjunction with Prof. Kennedy's report, from which we quoted last week, on the water power at the Touch reservoirs. According to the *North British Daily Mail* account, Bailie Lawson moved that the report be received, its conclusions adopted, and the Lighting Committee instructed to proceed with the carrying out of the instructions from the Commission at the point where they were interrupted in December. Mr. Ferguson seconded. Ex-Provost Yellowlees moved as an amendment that Prof. Kennedy's report be laid on the table, and the Commission remit to the Lighting Committee to get from an electrical engineer, who is a specialist in the use of water power, at a cost not exceeding 20 guineas, a further report, with guaranteed estimates, as to the utilisation of the water pressure available at the reservoirs for the electric lighting of the town. Mr. Yellowlees held that the report by Prof. Kennedy on the water power available at the reservoirs was founded on wrong data, and that his conclusions were entirely misleading. He had based his calculations not on the quantity of water available at the reservoirs, but on the quantity of water delivered in the town after deductions, which brought it down to one-half of the actual amount. Mr. Hay seconded the amendment, which was carried by 11 votes to 8.

Stockport.—It is stated that the electricity works will be in operation about September next.

Torquay.—Electric light was switched on at the Town Hall on 1st inst.

Wallasey.—Mr. Ellery said at the last Council meeting that the Gas, Water, and Electricity Committee was making a reduction of 17 per cent. on the charges for electrical energy.

Wells.—The Town Council has received a letter from the Electric Light Supply Corporation asking if the Council would sell its electric light provisional order, and the Town Clerk was instructed to reply that it was not in the market.

Worcester.—The electric lighting accounts for 1897 show that the receipts were £6,291 against £4,757 in 1896, and there was a loss on the year's working of £1,474 10s. 9d., against £1,616 in 1896 and £1,443 in 1895. The expenditure of capital up to the end of 1897 was £67,293. The enterprise, says the *Worcestershire Echo*, has not even earned the interest payable by nearly £500, to say nothing of depreciation, a word which is not to be found in the accounts. A most startling item is to be found in the table showing what has become of the electricity generated. The total in Board of Trade units was 559,275, of which there were used for public lamps 83,700; sold to private consumers, 325,130; used in works, 5,155; *quantity not accounted for*, 145,290, *more than one-fourth of the total!* Thus, roughly speaking, for about 25 per cent. of the expenditure, representing £1,000, there is no return whatever! When the accounts came before the City Council on 1st inst., Mr. Rushton complained that statements made by the chairman of the Electricity Committee (Alderman Williamson) as to the value of the water power had been falsified by the results. Alderman Williamson said the statements were made on the authority of the experts employed by the Council. Mr. Rushton moved a long resolution asking for reports upon various features of the working of the department. Mr. Charge suggested that the works at Powick should be abandoned, and a generating station started in the city. An amendment was eventually carried asking the committee for a report on the year's working similar to one given in the previous year.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Berlin.—In the annual report of the Great Berlin Horse Railway Company, it is said in reference to the electric working of the street railways: the existing electric working of the street railways first introduced in May, 1896, and extended on April 28th, and again on June 5th, has on the trolley section given the greatest satisfaction, and all the doubts and prejudices with which it was regarded at first have been dissipated. The power of despatching crowds of passengers by means of trailer cars has given especial satisfaction to the public, and it is to be hoped, in the public interest, that the use of trailer cars may be extended by authorities when the network is re-modelled. In accordance with the decision of the authorities, a number of sections, especially in the inner city, are to be worked by accumulators, which are to be charged from the trolley wire. The present conduit in the Lindenstrasse and in the Dennewitsplatz are to be done away with, and no more conduits will be constructed. This will obviate many difficulties in working and much blocking of traffic. A more important point for the future working of the lines is, that the authorities have directed that bogie cars shall in future be used. These have accommodation for 28 passengers inside; they run smoother, and the resistance on curves is greatly reduced. It is intended to construct these bogie cars in large numbers.

Berlin.—An electric tramway running east and west across Berlin and taking in the Leipziger Strasse, and traversing the Potsdamer Platz, the busiest thoroughfares in the city, was tried for the first time on Tuesday last week. It is intended to replace the horses gradually on all the urban tram lines.

Bournemouth.—The British Electric Traction Company has written to the Town Clerk, stating that it is still hopeful of laying such a scheme for electric tramways before the Corporation as might be satisfactory to all concerned. The directors are taking steps with a view to such a scheme being formulated.

Brighton.—Mr. Magnus Volk, who is now sole proprietor of the electric railway, has arranged to take the power necessary to run his cars from the Corporation electricity works in future.

Bristol.—Although a week or 10 days ago the prospects of a settlement being arrived at between the Corporation of Bristol and the Tramway Company with regard to the adoption of electricity on all the existing Bristol lines and on several new ones, were distinctly hopeful, the position has so far changed that popularly it is described by one word: "deadlock." The company (as reported in the ELECTRICAL REVIEW last week) replied in detail to the terms submitted by the Bristol Sanitary Committee, accepting some, rejecting others. Their answer was considered at a private meeting of the Sanitary Committee, at which some members expressed considerable surprise at the publication of the report of their electrical engineer, Mr. Faraday Proctor. This report had been sharply criticised by the company, and its statements with regard to the cost of electric traction denied in the most emphatic terms. Mr. Faraday Proctor, in consequence of his report being challenged, gave an explanation to the Committee, with which the Committee were satisfied. The Committee's decision on the question of terms raised two points of difficulty which at present there is no likelihood of settling by negotiation. The Tramway Company, in addition to the Bill which will empower them to adopt electric traction, has a second Bill authorising extensions of the system in several parts of the city. The new lines would amount to between 7 and 8 miles in length. The Sanitary Committee required agreement to the following condition: "The date at which the Corporation's power to purchase the power station and the proposed extensions will arise, to be the same as for the present horse tramways." In other words, that would be rather less than 15 years hence. The company agreed to arrange for the power station to pass when their existing lines are bought, but insisted on the full term, 21 years, of the Tramways Act for the extensions. The Sanitary Committee refused to give way, and the company talk of withdrawing their Extensions Bill. The second difficulty was not foreseen, and details cannot be given about it. It appears, however, that the Sanitary Committee has objected to the use of the trolley system in certain streets in which they do not think overhead wires are permissible. The company contends that the overhead system—the only one they had contemplated—is, practically speaking, the system which holds the field, and that other municipal authorities have selected it. Should the Extension Bill be withdrawn, the company will proceed with the Electrical Power Bill, and will be opposed by the Corporation. Meanwhile, several notices of Parliamentary opposition to the company's Bills have been given and the Great Western and Midland Railway Companies are among the opponents.

Cable Trams for Leith.—Mr. Colam, C.E., has been reporting to the Town Council on the cabling of tramways, and he estimates the cost of the conversion of the lines and the equipment, with all the necessary pits and machinery in same, at about £45,000.

Cambridge.—The directors of the Cambridge Street Tramways Company in their report say that they have had under consideration a proposal from the British Electric Traction Company for substituting electricity for horse traction on their system. The report stated "the great majority of the public recognise the superior facilities afforded by electric traction, and it was proved that such is the development of traffic on its adoption, that horse traction has no chance alongside it."

Dublin.—The Blackrock Town Commissioners are supporting the Bill of the Dublin Southern District Tramways relating to the speed.

Dundee.—The Corporation Tramway Bill (purchase and electric power) is being opposed by the North British Railway Company and the Caledonian Railway Company.

Ealing.—The proposed electric tramway scheme was again brought up at the last District Council meeting, a member having a good deal to say against the overhead trolley system. In fact, he deprecated even the laying of tram rails when there existed a likelihood that electric traction would shortly be possible without such disfigurements.

Finchley.—The District Council and the Hampstead Vestry are conferring for the purpose of opposing the electric tramway scheme.

Glasgow.—For the purpose of rendering it possible to use double-deckers on the Springburn electric tramway route, the level of Springburn Road underneath the Caledonian Railway bridge is to be lowered 15 inches, at a cost of £2,280, to be paid by the Tramways Department.

Hull.—The tenders for the remainder of the work in connection with the electric tramways, are now being discussed. The tenders for the supply of rails, and for hard wood, have been given out, also for the electrical plant, &c. The Board of Trade have made an order sanctioning a loan of £150,000, repayable in 30 years, for the purposes of the Hull Corporation tramways, such sum to be apportioned as follows, namely:—Permanent way, £123,200; land and buildings for electric generating station, £14,800; car sheds and depôts, £12,000. The Corporation estimates covering the balance of the loan requires further consideration, and the Board's decision will be communicated shortly. Tenders have been accepted for the supply of creosoted redwood stringers for tramways.

Leeds and Bradford Light Railway.—This scheme, which recently formed the subject of an inquiry by the Light Railway Commissioners, was before the Leeds City Council again last week, and the terms of the promoters were rejected, the previous resolution to oppose the scheme being confirmed.

Liverpool.—A deputation from the Tramways (special) Committee is going to Hamburg to inspect the working of the tramways there.

Manchester.—The representatives of about a dozen of the district councils affected by the Manchester Tramways Company's Bill have been conferring, with a view to arranging for opposition.

Norwich.—The Standing Orders Committee last week decided that the standing orders might be dispensed with on the condition that the provisions relating to Tramways Nos. 2 and 3 were struck out of the Bill of the Norwich Electric Tramways Company.

South Staffordshire Tramways Company.—At the annual dinner of the employés of the South Staffordshire Tramways Company last week, an important statement was made by one of the directors, Mr. S. R. Blundstone, M.I.M.E. He stated that the company last year was slowly but surely drifting on to the rocks, which meant liquidation. On one side they had £50,000 assets, and on the other side liabilities amounting to £73,000, but he was pleased to say their difficulties now seemed to have been overcome. The South Staffordshire Tramways Company had never paid a dividend, but at the next half-yearly meeting the shareholders would be asked to declare a dividend on the preference shares. Another important matter to the residents of Birmingham and Black Country districts was this, that it was proposed the South Staffordshire Tramway Company should form part of a vast overhead electric system, similar to those in vogue in America, and to cover a radius of 25 miles in Birmingham and the Black Country districts.

Swansea.—The British Electric Traction Company has taken formal possession of the property of the Swansea Tramways and Improvements Company. Possession was taken on Tuesday last week, by Mr. Emile Garcke, the managing director of the Traction Company, while Mr. E. W. Ruck, a director of the Tramways Company, with Mr. Kincaid, the engineer, represented the former owners in the transfer. The *South Wales Daily News* understands that there is no intention of making any change in the local management, and that directly the necessary authority is obtained electric traction will be applied. Our contemporary remarks that the British Electric Traction Company has taken up tramway concerns in different parts of the kingdom, which involve a capital of about £3,000,000.

TELEGRAPH AND TELEPHONE NOTES.

Delays in Australian Telegrams.—Australian papers recently to hand throw some light on the causes to which the interruptions on the Australian landlines are to be attributed. Under date, Adelaide, January 31st, we read that "The superintendent of telegraphs reports a partial telegraphic interruption on the Port Darwin line, owing to thunderstorms which have been raging between Powell's Creek and Port Darwin for the past two days. The line is also down between Perth and Roebuck Bay, all messages being sent *via* Port Darwin, adding greatly to the difficulties."

The Glasgow Telephone Report.—The report of Sheriff Jameson on the recent telephone inquiry held at Glasgow has not yet been placed before the public, though there seems some probability of its being issued any day now. The *Edinburgh Evening Dispatch* of 4th inst. thinks that the report will be issued in the course of this week, and adds: "On one vital point the Treasury has, it is said, satisfied itself. It may be assumed that the report pronounced the existing service to be unsatisfactory, and that some recommendation was made in the direction of a municipal licence. It has, however, been ascertained that there is a Parliamentary difficulty which, as the Treasury authorities believe, blocks the way. A telephone licence could not be taken up by the Corporation without the special authority of a Private Bill, inasmuch as the service extends beyond the municipal boundaries, and it is not competent for the Town Council to undertake any enterprise outside its own area."

In the House of Commons, last week, Mr. Caldwell asked the Secretary to the Treasury, as representing the Postmaster-General, if he was prepared to lay upon the table of the House the report and evidence taken by the Treasury Commissioner at the telephone inquiry in Glasgow, so that the same may be in the hands of members before the House goes into Committee on the Civil Service Estimates. In reply, Mr. Hanbury said that they had been laid on the table the day previous, and he would see that there was no delay.

Landlines in the Western Soudan.—As long ago as in August, 1895, we directed the attention of our readers to the steady progress with which the French Government landlines were being advanced eastward from Senegal. At that time the line was on the point of reaching Bamaku, on the Upper Niger, a distance of some 670 miles from the town of St. Louis on the coast of Senegal. We learn that since then the lines have been gradually extended, until, at the present day, they reach Waghadugu, which lies in the hinterland of the Gold Coast; a distance of 1,200 miles from St. Louis. We also learn that, running inland from Wydah northward through Dahomey, the line has reached the town of Pama, a distance of 360 miles; the gap now remaining between Waghadugu and Pama is about 170 miles, and when the junction is effected it will be possible to telegraph from the Bight of Benin to the Senegal coast by landline, a distance of 1,750 miles, by French landlines. We are glad to notice that the necessity of a system of landlines on the Lower Niger has been recognised by the British Government, and that it is proposed, at a cost of some £25,000, to effect communication with the Lower Niger through the districts to the north of Lagos and Forcados, the report running as follows: "It has been found necessary to incur special expenditure for the administration and defence of the northern territories of the Gold Coast Protectorate, and as the Colonial revenues are insufficient to meet such expenditure, the Imperial Government has agreed to give immediate assistance to the colony. The Imperial Government has undertaken to bear the cost of constructing a line of telegraphs from Lagos to Saka and Ogbomostro, thence to the Niger, and down the river to Forcados." A provision of £10,000 is asked for, to cover the cost of that portion of the line within the jurisdiction of the Colony of Lagos, which, it is believed, will be completed this year.

The Privacy of Telegrams—Speaking in the Commons last week on the question of the greater privacy of telegrams, Mr. Hanbury said the way in which telegraph offices were now arranged for the reception of telegrams was the result of long practice and experience, and the Postmaster-General thought they were on the whole conducive to the convenience of the public. Special inquiry would be made as to whether any further precautions were necessary.

Cable Interruption.—Amazon Company's cable beyond Obidos down March 9th, 1898.

The Telegraph Estimates. — The estimates for the Civil Services and Revenue Departments for the year ending March 31st, 1899, were issued last week. Under the Foreign and Colonial services the estimate for subsidies to telegraph companies has risen by £8,000 in consequence of the new subsidy to the Direct West India Cable Company in respect of the cable from Bermuda to Jamaica. In the Revenue Department, under "Post Office Telegraphs," a net increase is shown of £181,645 in addition to the sum of £28,800 voted as a supplementary grant last session. The grant for Post Office Telegraphs in 1897-98 was £3,182,990, and the total estimate for 1898-99 is £3,364,635, showing the increase of £181,645 as above.

The Telephone Service.—A deputation from the Belfast Merchants and Manufacturers' Association laid the question of municipal telephony before the City Council last week. The matter was referred to the Law and Improvement Committee for immediate consideration.

The Norwich Town Council has decided to petition the Postmaster-General for a municipal telephone license.

The Eastbourne Chamber of Commerce has passed a resolution in favour of municipal telephony.

A proposal to refuse to enter into negotiations with the National Telephone Company on the question of underground wires, was before the City Council last week.

The new Mutual Telephone Syndicate is still engaged communicating with various districts and towns in the provinces, endeavouring to get them to approve the principle of telephone competition. In some places the syndicate is receiving support.

CONTRACTS OPEN.

Belgium.—April 1st. The Municipal Authorities of Seraing are inviting tenders for the concession for the supply of electrical energy in the town for public and private lighting purposes during a period of 30 years. Particulars may be had from, and tenders to be sent to, the College des Bourgmestre et Echevins, Seraing, Belgium.

Bengal.—According to *Daily Tenders* the Bengal-Nagpur Railway Company wants tenders for the supply and erection of electric lighting plant for the bridges on the Bengal-Nagpore Railway over the Mahanadi River. Further particulars from the Superintending Engineer, Southern Division, Bengal-Nagpore Railway, Cuttack.

Berlin.—March 15th. The Municipal Traffic Deputation of the Town Council has opened a competition for the construction of several new electric tramways in that city. Exhaustive details concerning this project are contained in the *Elektrotechnische Zeitschrift* of the 13th inst., which mentions that proposals will be received by the Stadtische Verkehrsdeputation Rathhaus III, Berlin, by March 15th.

Blackpool.—March 22nd. The Corporation wants tenders for a tubular boiler, superheaters, condensers, rectifiers, boosters, transformers, lead-covered cables, arc lamps and pillars. Borough electrical engineer, Mr. R. C. Quin. See our "Official Notices" February 25th.

Darwen.—March 28th. The Corporation wants tenders for the supply of steam engine and dynamos, piping, accumulators, switchboards, mains, arc lamps, pillars, &c. See our "Official Notices" this w

Denmark.—March 12th. Tenders are being invited for the supply of the engines, dynamos, accumulators, &c., required in connection with the new central station at Frederiksberg, near Copenhagen. Tenders to be sent to the Frederiksberg Sporveis-og Electricitets Aktieselskab, Gammel Kongerie, 140, Copenhagen V., from whom particulars may be obtained.

Derby.—March 24th. The Corporation wants tenders for the electric wiring of the Lunatic Asylum and premises at Rowditch. See our "Official Notices" March 4th.

Devizes.—March 21st. Tenders are wanted for the supply and delivery of two 40 kw. continuous current belt-driven dynamos for the Wilts County Asylum, Devizes. Engineers, Messrs. Massey & Allpress, 25, Queen Anne's Gate, Westminster. See our "Official Notices" March 4th.

Edinburgh.—The City Council is inviting tenders for a host of stores and sundry articles. Among the items are "electric lighting materials for the Powderhall destructor," and "upholding of electric light installations." Particulars, &c, from the electrical engineer, Dewar Place.

Edinburgh.—March 22nd. The Council wants tenders for the additions and extensions to the electric lighting at the City Chambers. See our "Official Notices" this week for particulars.

France.—March 31st. Tenders are being invited by the Municipal Authorities of Saint Chamond (Loire) for the concession for the lighting of the public streets of the town, either by gas or electricity. Particulars from, and tenders to be sent to, La Mairie de Saint Chamond (Loire).

Leyton.—April 4th. The District Council wants tenders for the supply of two dynamos, one transformer, two gas engines and connections, and switchboards for extension of the electricity works. Electrical engineer, Mr. H. C. Bishop.

Manchester.—March 15th. The Great Central Railway Company (M. S. & L.) wants tenders for the supply of various materials and stores during 12 months ending April 30th, 1899. Among the items are asbestos packing, brass sheet and tubing, electrical materials, India-rubber, tin and zinc sheets, wire, &c. Particulars from Mr. A. W. Longden, storekeeper, at Junction Street Mills, London Road, Manchester.

Plymouth.—March 23rd. The Corporation wants tenders for the supply of alternating current meters for the year ending March 31st, 1899. Particulars from Mr. J. H. Rider, Borough electrical engineer, East Street, Plymouth.

Roumania.—March 15th. Tenders are being invited by the General Direction of the Roumanian Post and Telegraphs in Bucharest for the supply of 56,000 metres of galvanised iron and steel wire.

Southgate.—March 14th. The District Council wants tenders for an installation of electrical communication for fire brigade purposes. Surveyor, Mr. C. G. Lawson. See our "Official Notices" March 4th.

Spain.—March 21st. The Municipal Authorities of Santona (province of Santander) are inviting tenders for the concession for the electric lighting of the public streets of the town during a period of 20 years. Tenders to be sent to El Secretario del Ayuntamiento de Santona (Santander) from whence full particulars may be obtained.

Switzerland.—April 30th. Plans and estimates are being invited, says the *Contract Recorder*, by the Government authorities of Fribourg, Switzerland, until April 30th next, for a projected electricity generating station to be established at Hauterine. Water-power is to be utilised, and the station will have a capacity of about 6,000 H.P. A premium of £120 will be awarded to the three schemes submitted which are considered to be the best. Plans and estimates are to be sent to the Department des Travaux Publics, Fribourg, Switzerland, from whence full particulars of the competition may be obtained.

The War Office.—April 27th. The Secretary of State for War is prepared to receive offers, competitive designs and specifications for the supply of portable electric search light apparatus. Particulars from the Director of Army Contracts, War Office, Pall Mall, S.W. See our "Official Notices" February 4th.

Victoria.—March 21st. The Telegraph Department of the Victorian Government Railways is inviting tenders for the supply of alternating current transformers and one main switchboard. Tenders to the Telegraph Superintendent's Office, Spencer Street, Melbourne.

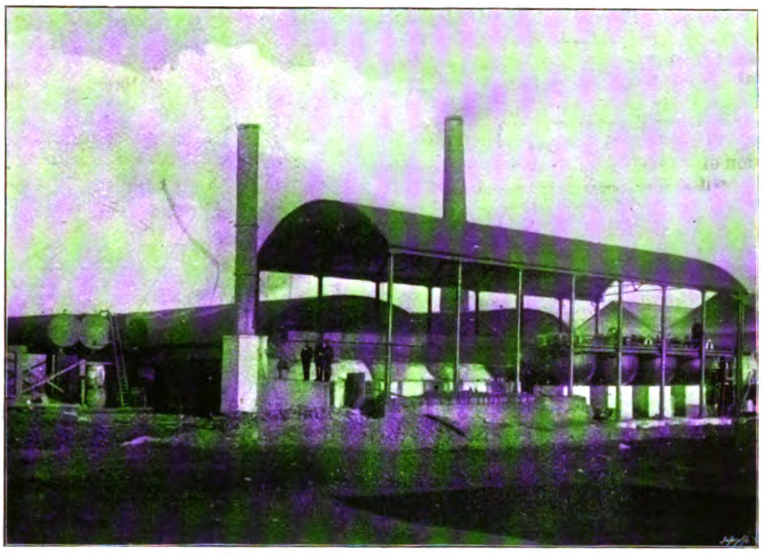
Victoria.—June 24th. The Council of the city of Hawthorne (Colony of Victoria, Australia) is inviting tenders for the supply and erection of buildings, boilers, engines, dynamos, transformers, mains, meters, arc lamps, poles; also running the plant for three years. See our "Official Notices" for particulars.

Wallasey.—March 17th. The District Council wants tenders for the supply of engine, alternator, exciter, two Lancashire and one water-tube boilers, and condensing apparatus. Engineer, Mr. J. H. Crowther. See "Official Notices" February 11th.

Watford.—March 16th. The District Council wants tenders for the supply and erection of various plant for the electric lighting of the district. For details of the seven sections see our "Official Notices" February 11th. Mr. W. C. C. Hawtayne, consulting engineer.

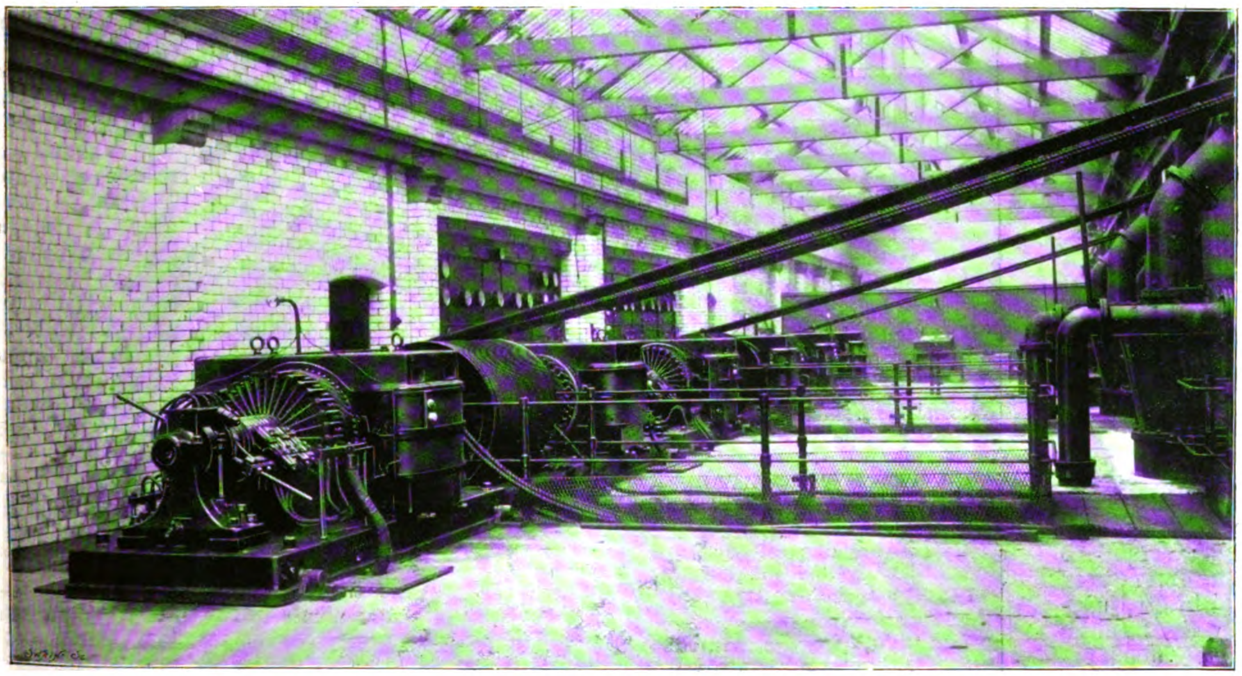
THE MANUFACTURE OF ELECTRO-CHEMICAL PRODUCTS.

There has been always more or less mystery associated with the electro-chemical industries, and probably the difficulty of penetrating into the inner recesses of such processes has been to some extent responsible for much of the legendary lore that has gathered round them. Occasionally the corner of the veil has been lifted, and one has been permitted to gaze upon what after all has been neither very mysterious nor especially wonderful; but, speaking generally, it is as difficult for a stranger to enter the gates of electro-chemical works as it is for an explorer to reach the City of Lhassa. With one or two conspicuous exceptions, there have been no places so jealously guarded from the inquisitive eye as copper depositing works. So rigorous are the rules in one well-known manufactory, that if it is necessary to introduce an outsider into the works for repairing plant or other specific purpose, he is usually conducted blindfolded to the spot where his services are required; yet the quality of the electrolytic copper produced at these works is not higher than that deposited in places where less secrecy prevails. With the migration of officials and workmen, and occasionally from other causes, it would seem almost impossible to keep any chemical or electrical processes completely concealed. There may be certain details of plant or process that it is desirable to keep within the four walls of the place where they have been evolved, but we do not think that there is much to be gained from a complete seclusion. Moreover, we think that where persistent attempts have been made to keep the details of a process secret, there is always more difficulty in dealing with supposed infringers.



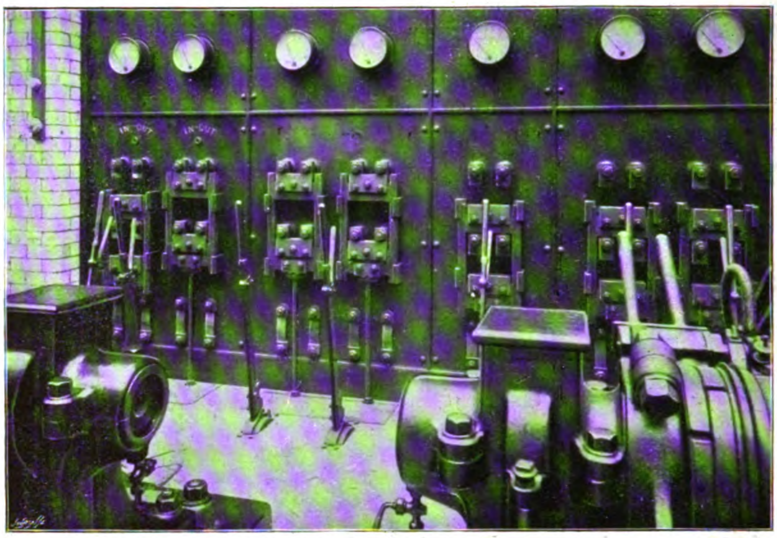
Chlorate of Potash Plant.

It is hardly necessary to say that electricity in many chemical processes has proved to be invaluable, and that this application of electricity is destined to be one of the most fruitful, is strikingly shown by the rapid development of the electro-chemical industry. Although considerable commercial success has been achieved in the use of electro-chemical processes, they, at any rate in their initiatory stages, call for extraordinary care; they may be, and no doubt when compared with older methods, are delightfully simple, but unless some regard be paid to the economical apportioning of the electric current for the necessary function of electrolysis, it is not difficult to realise that the process might prove an expensive one. The whole basis of the electro-chemical industry is that electricity offers a cheaper means of obtaining certain products than can be obtained by ordinary chemical methods; but the operations necessitate the continuous running of electrical machinery, and even with the most economical engines, the amount of coal burnt per annum, even in works of moderate output, must be considerable. As Mr. Andreoli pointed out in these columns some years ago, electrolytic works ought to be established in districts where coal and salt are cheap, and this is a necessary condition of the possibility of the competition of electrolysis with the chemical production of chlorine and caustic soda. It can, we suppose, be said of almost all the electro-chemical companies in this country, that they have settled in districts that are contiguous if not actually in the coal fields, and where salt is at the same time abundant.



General View of Engine Room.

It is not proposed in this article to deal generally with the subject of electro-chemical production of chemicals, but rather to give an account of the methods adopted in one well-known works for the manufacture of caustic soda, bleaching powder, and chlorate of potash. The Electro-Chemical Company, of St. Helen's, have been courteous enough to comply with our request to inspect their works, and to show the various processes in operation. There are some details connected with the works that the company has been compelled to withhold from us, but in spite of that there is probably considerable interest attaching to the following descriptions and illustrations.

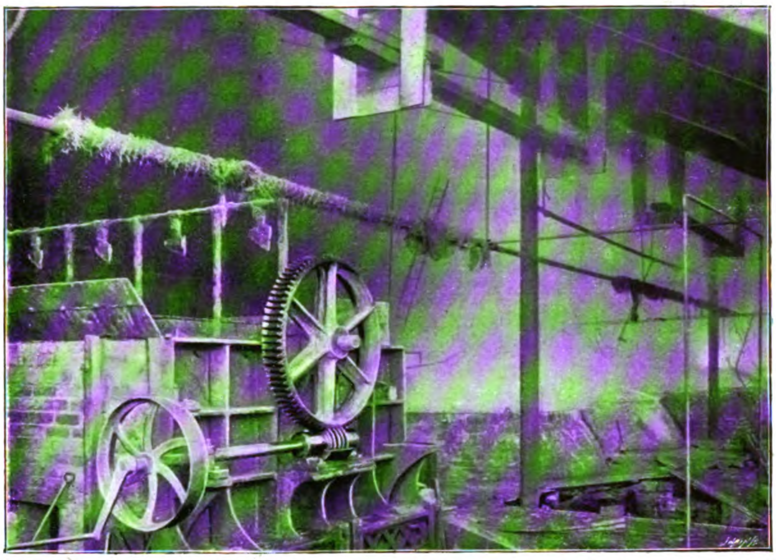


View of Switchboard.

In 1892 we drew attention in these columns to the establishment of works at Snodland, in Kent, for the purpose of demonstrating the production of caustic soda and bleach by means of electrolysis. The process was known as that of Holland and Richardson, and it may be reasonably conceived that a considerable measure of success attended the Snodland experiments, for sometime afterwards the Electro-Chemical Company was formed to work the system on a commercial scale at St. Helen's, Lancashire. It is hardly necessary to say that this town forms practically the centre of the electro-chemical industry, it being in close proximity to the coal pits and within a short distance of Cheshire, from whence salt is procured, which is, of course, the basis of the electro-chemical products manufactured here. The site upon which the electrical company's works are erected seems to be an eminently suitable one, judging by the facilities of transport furnished by the adjoining mineral line of the London and North-Western Railway Company. The works are connected by sidings to this line, while a portion is bounded by the St. Helen's and Mersey Canal.

Electrolytic Tanks.

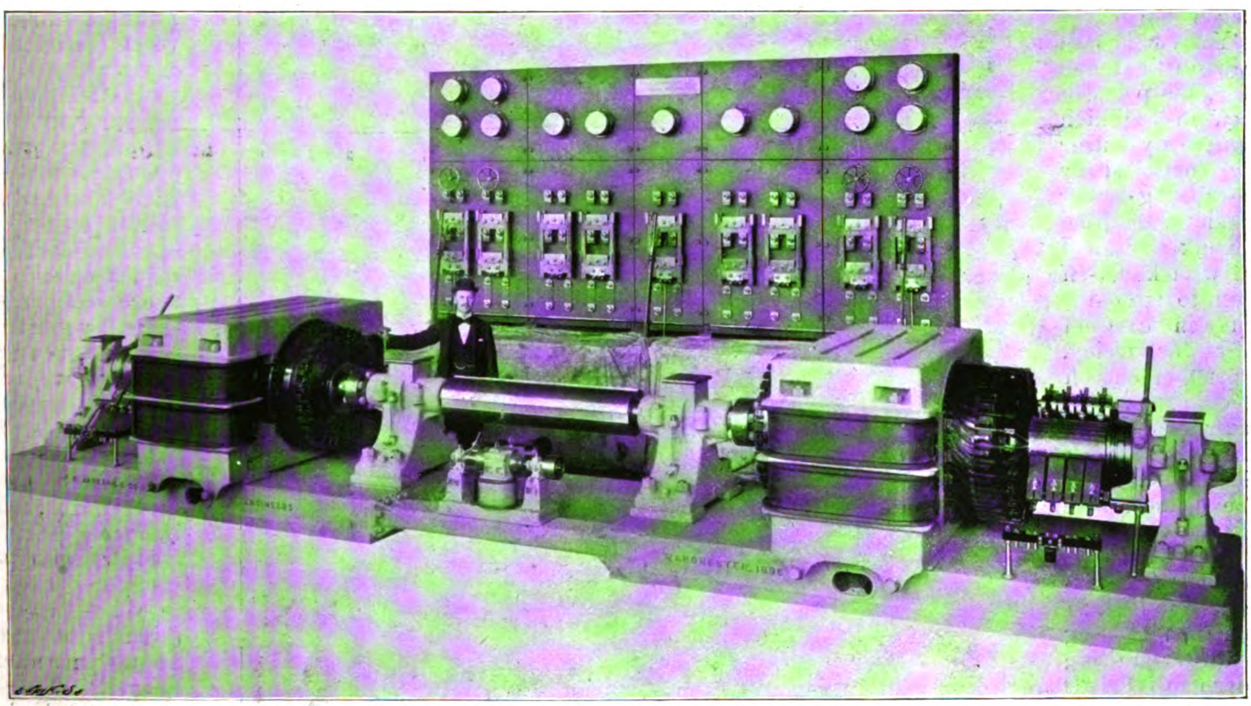
The three principal products have been already alluded to. The caustic soda is very extensively used in the manufacture of paper and soap, the chloride of lime (bleaching powder) is used to a great extent in the various processes of bleaching, and chlorate of potash which forms the third branch, constitutes a very important part of modern explosives. The production of these by an electro-chemical process is comparatively simple. Reduced to its elemental form, it is practically the decomposition of salt by means of electric current which gives chlorine gas at the anodes; the solution becomes gradually weaker in salt and stronger in alkali, and forms caustic soda. To be a little more precise, we may say that salt is first dissolved in what is known as the brine house. It is placed with water in a tank, in which it is agitated by mechanical stirrers until it has reached the requisite strength. The next operation is to run off the brine thus formed into settling tanks. The liquid being eventually drawn off into a final settling tank placed at a higher level. From this level the decomposing tanks are supplied with brine as required, the feeding of the tanks being a very simple operation, permitting each and every cell to be fed by merely turning on a few taps. The decomposing cells next merit our attention, and a glance at one of the illustrations will give a rough idea of the size of this plant. The cells are in what is known as the tank house, and are arranged in tiers. The tanks are 20 feet long × 3 feet wide and 1 foot 3 inches deep, and are divided into 16 cells. The anodes take the form of irregular blocks of carbon embedded on a lead strip, which is fixed in an earthenware box, as shown in the illustration. The anode box is inverted in the cell, but does not quite reach the bottom, thus permitting the liquid to circulate freely inside. A simple wrought-iron grid forms the cathode. As the current enters the cell chlorine gas is given off in the anode chamber, and the solution, after decomposition, becomes, as we have said, stronger in alkali and weaker in salt. In order to maintain the solution at the requisite strength, brine is fed into the tanks, and after a period a certain percentage of alkali is reached, and the solution becomes, to all intents and purposes, caustic soda. The hydrogen which is formed passes off into the atmosphere, the construction of the tank house permitting air to pass through freely. Having now obtained, by electrolytic methods, chlorine gas and caustic soda, the next step is to conduct them from the tanks for treatment. The chlorine gas, as it is given off, passes through a port hole into a closed conduit running the whole length of the tank, this conduit being connected to an earthenware main which runs from the tank house to the bleaching chambers and to the chlorate of potash plant. The use of the chlorine gas, to which we shall draw attention first, is in the making of chloride of lime. Lime is first prepared, and after being well riddled is spread upon the floors of bleaching chambers to a depth of about 6 inches; in order to present a greater surface it is arranged in furrows. There are five bleaching chambers, which are shown in one of the illustrations; the dimensions of each being 80 feet by 30 feet, and 5 feet 6 inches in height. When the lime has been spread upon the floor, the doors are sealed, and the chamber made



Caustic Soda Plant.

difficulties arising from the formation of CO_2 do not trouble them, they have no difficulty whatever in maintaining their bleaching powder at market strength. The next operation in which the chlorine gas figures is in the manufacture of chlorate of potash. In this case the chlorine is passed over milk of lime in absorbers, and the calcium of chlorate formed is run off and settled. The clear liquor is concentrated in pots, to 60° twaddle, chloride of potassium is then put in; from this potassium chlorate is obtained, which is run off into pans. Crude crystals are then obtained, and the mother liquor being drawn off, the crude crystals are re-dissolved by steam. This is run into lead coolers for final crystallisation; then comes the washing and drying process, and the chlorate of potash is ready for market. One of the illustrations shows an exterior view of the chlorate of potash plant.

The second product of the electrolytic process, viz., the caustic soda, is run off into large tanks in the caustic soda shed. There is a certain percentage of salt present in the solution when it has left the decomposing tanks, and the fluid is treated to a kind of preliminary evaporation process, in which the salt is precipitated and removed. The method of removing the salt is the employment of a revolving frame,



View of Switchboard and Dynamos before Erection.

air-tight in every way. The chlorine gas is then admitted into the chamber through connections in the roof. After the chlorine has acted upon the lime for some four or five days, there is formed chloride of lime, which is known commercially as bleaching powder, the strength of which varies from 35 to 37 per cent. of available chlorine. When this stage has been reached, the chloride of lime is discharged through shoots in the floor of the chambers into casks, and is then packed. It is claimed by the Electro-Chemical Company that as the

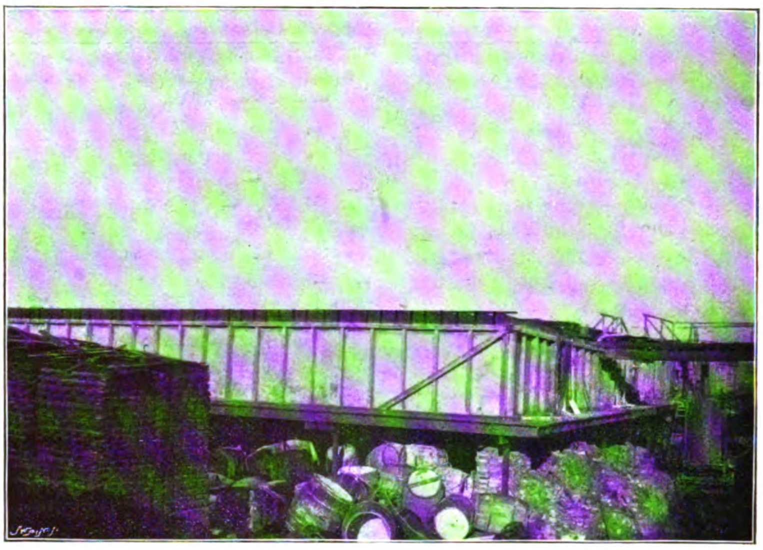
shown in one of the illustrations, which practically shovels out the salt from the bottom of the receiving tank. This salt is re-dissolved and used over again in the electrolytic tanks. In the caustic soda shed are 14 concentrating pots in which the solution is finally treated. Each pot has a furnace underneath, and in these the caustic soda is evaporated down to the required density and becomes ordinary commercial caustic of varying degrees of strength, according to requirements, the principal demand being for caustic having a strength of 70 per cent. The caustic, while in a fluid state, is run off into iron drums, in which it immediately solidifies.

That is practically a rough account of the chemical process. Turning from this to the generating plant, we find what is undoubtedly a very interesting section of the Electro-Chemical Company's works. The steam raising plant consists of 10 Lancashire boilers by Beeley & Co., of Hyde, which are constructed to work at 160 lbs. pressure.

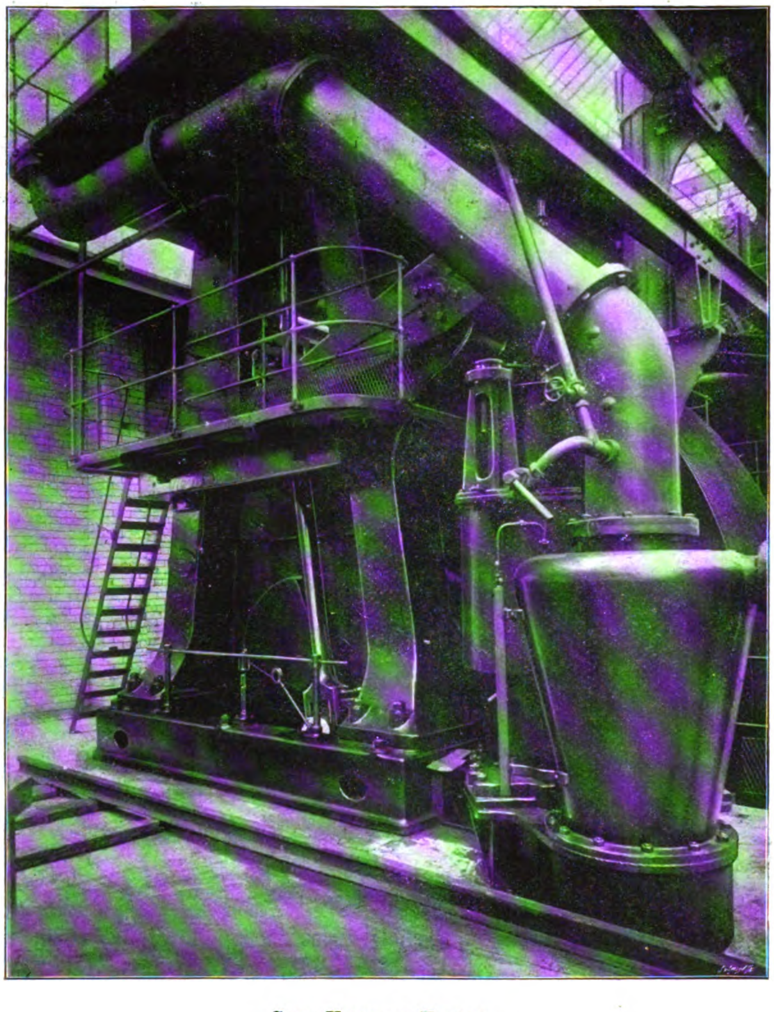
The engines have been made by Yates and Thom, and are excellent specimens of the marine type. They are vertical, inverted, compound, condensing, with cylinders 22½ inches and 46 inches diameter, 4 feet stroke, of very strong construction; the cylinders are jacketted in the bodies, and fitted with Corliss valve gear throughout, the valves and passages being constructed to give the minimum amount of clearance; the steam valves of both cylinders are fitted with Yates & Thom's patented release motion, the point of cut off in the high pressure cylinder being controlled by a high speed governor driven by wheels from the crank shaft, and fitted with knock-off motion to stop the engine in case of accident or racing, the point of cut off in the low pressure cylinder is adjustable by hand whilst the engine is running.

The cylinders are placed side by side with cranks at right angles, the fly-rope pulley wheel, 21 feet diameter, being placed between them; the dynamo is driven from the periphery of the pulley by 26 ropes, each 1½ inches diameter. The crank shaft and crank pins are of steel, with large bearing surfaces suitable for continuous running.

The air pump and condenser are placed behind the low pressure cylinder on the floor of the engine house, the air pump being worked by levers from the low pressure cross head; the injection water is taken from the canal, and the hot well is placed at such a level that the water, after being drawn from the condenser by the air pump, returns to the canal by its own gravitation.



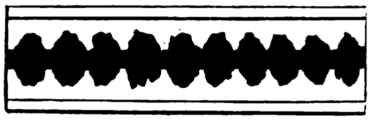
The Bleaching Chambers.



Side View of Engine.

The present working steam pressure is 135 lbs. per square inch, for which pressure the engines have been constructed. The engine house has been designed for five engines, of which three are at work, and a fourth on order, but there is still ample room left for the arrangement of additional plant. On August 25th last, No. 2 engine was tested for steam consumption, and this, as measured by the actual amount of feed-water pumped into the boilers, worked out to 14 lbs. of steam per horse-power per hour throughout the test, which lasted six hours. During this test the average indicated horse-power of the engine was 711·35.

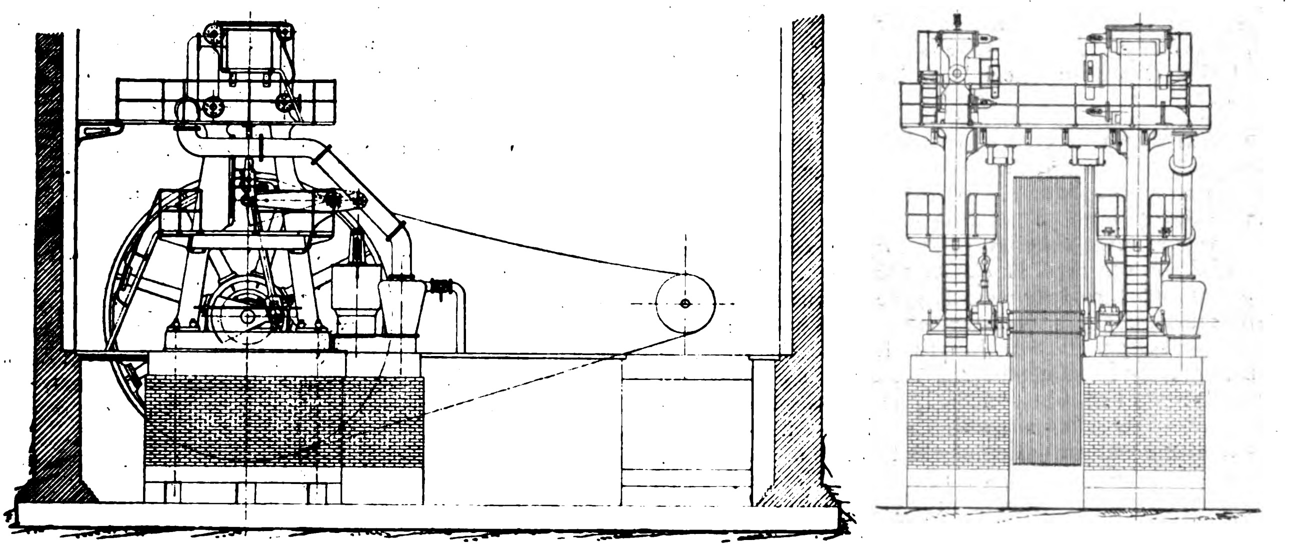
The dynamos, which are of a special type, built by Messrs. P. R. Jackson and Co., of Manchester, with Sayer's windings, are arranged in pairs, the engine driving on to a shaft connecting the two machines together. They each develop 1,250 amperes at 180 volts when driven at 400 revolutions. The pedestals of the machines are of the self-oiling type, and are fitted with anti-friction metal of a special brand. The armature shafts are of mild steel, with solid flange couplings on the pulley shaft. End play is taken up by the collars in the centre of the pedestals on either side of the pulley. The armature core plates are of Swedish iron, and are insulated from one another with copal varnish which is applied evenly through the medium of a pneumatic sprayer. The core plates are held firmly on the shaft by keys and heavy end-plates, and the interior of the core ventilated by means of longitudinal channels provided along the interior of the discs. The main armature bars are of solid copper, and are first insulated with unbleached tape of good quality, and then varnished with a special composition. They are afterwards insulated with mica cloth, and finally protected all round with thin strips of well seasoned mahogany. It is claimed that this insulation has effectually withstood the injurious effects of chlorine gas, though probably only traces of this reach the engine room. The pole pieces and field magnet castings are of Messrs. Jackson's special mild steel of their own manufacture. The top and bottom halves of these castings have been designed to provide for Sayers's



ANODE BOX SHOWING ARRANGEMENT OF CARBONS.

auxiliary poles, and at the same time to reduce the number of joints. The lateral position of the field magnets, which, together with the pedestals, are insulated from the bed plate with thick zinc blocks, can be adjusted at will by set screws. The switch gear, which has been built under Mr. Slater Lewis's patents, is of the simplest possible character, and is worked by a system of railway levers, a long and quick break being provided by this means. The distribution is accomplished through a bare stranded cable, and an interesting feature about it is that there are no joints at places where branches of the mains are taken, the method adopted being simply to untwist a strand.

The generating plant is arranged in a lofty well-arranged building, shown in one of the illustrations, which has been prepared from a photograph lent by Messrs. Jackson.



SECTION AND END.

CONTRACTS CLOSED.

Belfast.—The Corporation last week confirmed the Electric Committee's acceptance of the tender of Messrs. T. Parker, Limited, to supply by October next an additional 200-kw. steam dynamo for lighting and traction at £2,646. The reference of the electric traction matter to a committee for investigation was also approved.

Brighton.—For the supply of dynamos, motors, switchboards and wiring work for the Municipal School of Science and Technology, the contract has been given to Messrs. Warburg and Dymond at £481.

Hammersmith.—The Vestry last week accepted a tender from Messrs. Ferranti for supply, &c., of new switchboard for electric lighting extensions at a cost of £473, and gave a contract to Messrs. Babcock & Wilcox for boilers at a cost of £1,060. Messrs. Ferranti will also alter panels on the present switchboard at a cost of £12.

Italy.—La Società Italiana di Elettricita, Sistema Cruto, of Turin, has secured the contract for the supply of the incandescent lamps and lampholders required by the torpedo and electrical material department of the Navy Yard at Spezzia.

Shoreditch.—The Vestry has entered into a contract with the British Insulated Wire Company for laying about 2,000 yards of conduit for electric lighting mains, at 9s. 8d. for three-way and 8s. 6d. for two-way conduits, these prices including excavating and reinstating the street, and supplying material.

NOTES.

London Electric Omnibus Company, Limited.—The report of the committee of this company, which can be seen in our City pages, forms pretty reading, and the practical test which Mr. Spagnoletti considers most encouraging and very satisfactory only goes to show he must be very easily satisfied. Mr. J. Elliott Condict, too, boasts of the satisfactory nature of last month's test, because, forsooth, they were able to find *the exact amount of voltage and the number of amperes used!* Can it be possible that these figures have never been ascertained previously? The results obtained with the 26-passenger 'bus, carrying, however, only 17, have been submitted to us, and briefly stated are as follows:—The vehicle ran from Trafalgar Square to Hammersmith Broadway, and back to Whitehall, a distance of 14 miles, in 1¾ hours, inclusive of a 17 minutes' wait at Hammersmith. The day was perfectly dry, the roads clean, and with one exception, viz.:—Haymarket, the route to Hammersmith is fairly level. The return was made on a road still more favourable for the 'bus, but had the day been wet, with greasy streets, it is doubtful whether it would have reached home without assistance. Readings of current and voltage were taken every 5 minutes, the amperes averaging 39 and the volts 230, or an average of 12 horse-power electrical. It is stated that at the end of the run enough electrical energy remained in the battery for 11 miles further; but we need not, at the moment, consider this. The question is, whether there is not a great loss of electrical energy somewhere. 18,000 watt-hours taken from the battery during a trip of 1¾ hours means 9 units per hour, and when we take into consideration the loss between the terminals of the charging dynamo and the battery, it appears to point to the fact that radical changes are required, both in the technical and managerial departments of this company before commercial success is likely to be assured, or the horse-drawn 'bus become a thing of the past. Can it be that motor and gearing are both inefficient; if this is so, no battery, however good, can show to much advantage; but the claims made for the Sola accumulator have certainly yet to be verified.

Secondary Battery Testing.—A correspondent calls our attention to a description of the Lamina accumulator in a recent issue of the New York *Electrical Engineer*, in which is published an abstract from a report made by Prof. S. P. Thompson. "The 14 watt-hours per pound weight (gross) of the cell," says the writer, "has been obtained by a particular method of testing and calculating out the results. The Lamina people themselves claim only 9 watt-hours for their best cells of large size." The sooner experts adopt some uniform method of testing accumulators the sooner will the various types on the market be properly comparable amongst themselves.

New York Electrical Society.—An interesting sequel to the reading of Mr. Dana Greene's paper on "The Relations between the Customer, Engineer, and the Electrical Manufacturer," is the passing of the following resolution by the New York Electrical Society, before which the paper was read :—

Resolved.—That in view of the excellent suggestions and recommendations on standardising apparatus embodied in Mr. S. D. Greene's paper, the Society hereby expresses its approval of efforts in that direction, and invites the American Institute of Electrical Engineers to consider some comprehensive plan for such standardisation of American apparatus for electric light and power.

The Society, which appears to be a very energetic one, desirous of bringing the "public into more intimate relations with the scientific aspect of all classes of electrical work," will have a booth and *rendezvous* for its members and friends at the electrical exhibition which is to be held at Madison Square Garden in May. The exhibition will last a month, and it is proposed to make it surpass anything of the kind ever done in New York. The Society has received a grant from the exhibition authorities for its educational work. The Electrical Society is anxious to put itself prominently before the public, and to show that, though the oldest electrical body in America, it is not suffering from senile decay, but has yet much energy left. Before the Society, on February 11th, Mr. Joseph Wetzler gave an illustrated paper on "Electricity Direct from Coal." A discussion followed.

The American Eagle.—Some eagles recently alighted on an electric transmission line in California, and in consequence nothing was left of them but one skull, four feet, and part of legs. The talons were clutched tightly to the line wires. Not a vestige of the bodies or feathers of either bird, nor the head of one of them, could be found. The *Journal of Electricity* recently gave a gruesome sketch of the remains. The circumstances are as follow:—The generating plant of the San Joaquin Electric Company, of Fresno, Cal., was one day pumping 10,000 volts serenely into the transmission line, when suddenly one of the circuits developed a dead short circuit, with the almost instantaneous open-circuiting and grounding of the two legs of the circuit, which were on the upper cross arm. This, of course, interrupted the service in Fresno, and the ground thus thrown on was so severe, that it became impossible to burn it out. After a few minutes' delay the service was resumed over the second transmission line, which had remained uninjured. Linesmen were sent out at once to ascertain the cause of the trouble and repair the broken circuit, and after having gone over nearly 30 miles of line, they reached a mountain top about five miles from the power house, where the break was discovered, also the eagles' remains. A specimen was found which shows the terrific heat of the electric arc. The soil along the pole line at the place indicated consists of pure granitic sand, which, wherever the wire touched the ground, had become melted into glass, and even a piece of quartz had been fused and run in together with the glass. The circumstance of the accident suggests a theory for it, as evidently the two eagles alighted on different legs of the three-phase circuit, within close proximity to each other; that they actually came into contact, and in so doing, formed a short circuit, which not only incinerated the eagles, but threw the wires into short circuit, and burned them off.

Engineering Strike.—The newspaper press says that last week Messrs. Tangye forwarded a cheque for £500 to the Engineers' Federation of Masters, and one of similar amount to the Men's Association, to help to cover the loss incurred in the recent strike. The Masters' Federation have returned the cheque, on the ground that Messrs. Tangye would give them no assistance during the struggle. The federated firms in Birmingham hope to contribute a cheque of the same amount.

It is also stated that trouble has arisen at the Hull Engineering Works. The employers proposed to overtake the arrears of work by starting night shifts, and the men demanded pay at the rate of a day and a half, whereas the employers would only consent to a day and a quarter. Last night a number of the men at various establishments declined to accept the employers' terms, and this morning the employers refused to allow them to start again.

Annual Dinner.—The annual dinner of the London Electric Supply Corporation's engineers, past and present, was held in the Hotel Florence, Rupert Street, Piccadilly, on Tuesday evening, the 1st inst. Among those present were Mr. P. Walter D'Alton, Messrs. S. Z. de Ferranti, G. W. Partridge, H. W. Kolle, C. S. V. Clirehugh, Reginald P. Wilson, J. K. Stothert, G. K. B. Elphinstone, Henty, A. M. Billington, McDougall, and J. Hardie McLean. After dinner, to which some two dozen sat down, Mr. Ferranti proposed "Success to the London Electric Supply Corporation," coupling with the toast the name of Mr. D'Alton. He regretted the absence of Mr. C. P. Sparkes, who had been associated with the undertaking from the first until his retirement a few years ago, and who had rendered signal service in the initiation of the system. He was pleased to see the success which had attended the undertaking. Being the pioneer system of supplying vast areas from one centre, it had to pass through a trying period inseparable from a pioneering concern of such magnitude. It had at last emerged triumphant, and this was no doubt a source of gratification to them all. Our American cousins had acknowledged the correctness of the principle, and were in some cases even closing their present stations and establishing one centre of generation for each city. He had much pleasure in giving the toast of "Success to the London Electric Supply Corporation," and in coupling with it the name of Mr. D'Alton, its capable engineer, who had by his untiring energy and careful management, assisted by an efficient staff, contributed materially to its success. Mr. Walter P. D'Alton in a few appropriate words acknowledged the compliment to himself and staff, and confidently spoke of the continued success of the corporation. Mr. Kolle replied to the toast of "The Engineers of the Past," and in a happy speech recalled some incidents peculiar to central station engineers of the early days, which one can afford to laugh at after a period of 10 years, but which were regarded in quite another light at the time. Contributions to the enjoyment of the evening were supplied by Mr. Elphinstone in his screamingly-funny stories told in native dialects, by Mr. Partridge with his banjo and his song, "Wait till the fogs roll by," and by Messrs. Wilson, Kolle, Stothert, and Hardie McLean, in songs of a more or less varied character.

Electric Pumping Plant in Collieries.—An electric pumping plant, recently installed at the collieries of the Delaware, Lackawanna and Western Railroad Company at Bellvue, Pa., differs somewhat from the type common for this class of work. The usual design followed consists of a three-throw pump with plungers driven by cranks placed at 120° from one another. In the present case, double-acting ram pumps, having plungers in front and behind, the latter coupled by outside rods to the cross-head, are used, and there are two sets of such pumps side by side, each 10 inches diameter × 15 inches stroke, so that in all there are four pairs, and these driving cranks are set at 90°. The motor is of the four-pole type, with carbon brushes, and allow of a variation from no load to overload without movement of the brushes. The work done is 800 gallons per minute against 150 feet head, about 36 actual H.P. in the water, the rated capacity of the motor being 50 H.P. The plant was built by the General Electric Company at Schenectady, N.Y.

The Royal Society.—The following papers were down for reading yesterday afternoon:—(1) "On the Rotation of Plane of Polarisation of Electric Waves by a Twisted Structure." (2) "On the Production of a 'Dark Cross' in the Field of Electro-Magnetic Radiation," by Prof. J. C. Bose. "An Extension of Maxwell's Electro-Magnetic Theory of Light to include Dispersion, Metallic Reflection, and Allied Phenomena," by E. Edser. "On the Relative Retardation between the Components of a Stream of Light Produced by the Passage of the Stream through a Crystalline Plate, Cut in any Direction with Respect to the Faces of the Crystal," by J. Walker. "On the Relation between the Diurnal Range of Magnetic Declination and Horizontal Force, and the Period of Solar Spot Frequency," by W. Ellis.

Correction.—On page 288 of our last issue, first column fourth line, 500 volts should read 5,000.

Removing Rust from Iron Electrically.—A very simple and effective way of cleaning rusted iron articles, no matter how badly they are rusted, consists, according to Carl Hering in the *Electrical World*, in attaching a piece of ordinary zinc to the articles, and then letting them lie in water to which a little sulphuric acid is added. They should be left immersed for several days, or a week, until the rust has entirely disappeared, the time depending on how deeply they were rusted. If there is much rust a little sulphuric acid should be added occasionally. The essential part of the process is that the zinc must be in good electrical contact with the iron; a good way is to twist an iron wire tightly around the object and connect this with the zinc, for which a remnant of a battery zinc is suitable, as it has a binding post. Besides the simplicity of this process, it has the great advantage that the iron itself is not attacked in the least as long as the zinc is in good electrical contact with it. When there is only a little rust, a galvanised iron wire wrapped around the object will take the place of the zinc, provided the acid is not too strong. The articles will come out a dark grey or black colour, and should then be washed thoroughly and oiled. The method is specially applicable to objects with sharp corners or edges, or to files and other articles on which buffing wheels ought not to be used. The rusted iron and the zinc make a short circuited battery, the action of which reduces the rust back to iron, this action continuing as long as any rust is left.

Researches in Magnetism and Diamagnetism.—At the Royal Institution on Thursday, last week, Prof. J. A. Fleming gave the first lecture of a course on "Recent Researches in Magnetism and Diamagnetism." The lecturer said he had selected his subject before he became aware that this course constituted the annual series of lectures delivered to commemorate the late Prof. Tyndall. There seemed, however, a special appropriateness in the selection he had made on account of the attention bestowed on the subject of diamagnetism by the late distinguished occupant of the chair of Natural Philosophy in the Royal Institution. Prof. Fleming introduced his subject with a few remarks on the terminology of magnetic science, which he stated to be now based on the view that magnetic effects were due to actions taking place in the space-filling ether. He proceeded, says the *Times* report, to illustrate, by simple experiments, the production and measurement of magnetic force, magnetic flux, and magnetisation. Devoting the rest of his lecture to the study of the so-called ferro-magnetic metals, iron, nickel, and cobalt, he pointed out that their unique qualities showed them to possess, in the solid condition, a special molecular structure not found in other materials to anything like the same extent. Numerous interesting experiments were then performed to illustrate the changes produced in an iron bar when subjected to magnetisation. The discovery made by Joule in 1842, that an iron bar lengthened on being magnetised, was demonstrated with the aid of an ingenious piece of apparatus, as also was the fact more recently noticed by Bidwell, that under very strong magnetisation it actually became shorter. The slow establishment of the magnetic state in large masses of iron, and the sluggishness with which magnetic changes in iron followed the magnetising force, were illustrated by instructive experiments. The molecular changes or magnetic noises occurring in iron on rapid magnetisation and demagnetisation were next discussed, the lecturer observing that they really formed the starting point for the invention of the telephone. A concluding series of experiments illustrated the remarkable effects produced on the magnetic qualities of nickel by twisting or pulling it. The second lecture of the series was to be delivered yesterday afternoon.

Electricity in a Brickyard.—According to the *Peterborough Express*, some new brickyards which are to be laid out at Whittlesea will not only be lighted by electricity, but the machinery will be electrically driven. The boiler, engine and dynamo house are to be conveniently placed near to water supply, sufficient to allow of the employment of the most economical form of condensing engine. The power required for driving the machinery will be conveyed from the dynamos to motors fixed in each machine house. The plant at present contemplated is capable of turning out about 500,000 bricks a week.

Electric Floor Scrubbing Machine.—Our American exchanges describe an electric floor scrubbing machine, invented by Mr. H. F. Ackerman, of Cleveland, which is claimed to do work in one-fourth of the time required in the old way, at a saving of 75 per cent. of the cost. The machine is operated by an electric motor, which receives its current through a flexible cord, connected to any convenient incandescent socket. A reel at the top of the trolley pole takes up the slack cord, and unwinds it in the operation of the machine. The frame carries three scrubbing brushes, which are pressed against the floor with a spring pressure. The brushes are geared with the motor, so as to revolve at a speed of 400 revolutions per minute. The gearing between the motor and the brushes is by means of a sprocket chain, leading from the motor to the axle, on which the larger wheels loosely revolve, and from that axle by another sprocket chain to a shaft connected by bevel gears with vertical shafts, to which the brushes are attached. This permits of the machine being used as a hand machine, in case no electric current is available to operate it by electric power. For the scrubbing brushes, sandpaper blocks or blocks of stone may be substituted, and thus the machine may be used to dress down wood floors or mosaic. The springs always keep the brushes in proper contact with the floor. A suitable rheostat or governing device is provided on the handle, and the motor is fully protected by fuses. The machine weighs about 300 lbs., and its frame is about 30 inches square. The three brushes are so arranged in relation to one another, that the short axis of the middle one is always parallel with the longer axis of the side brushes, and *vice versa*. Hence, in operation, the machine scrubs a path as wide as the distance between the outer ends of the side brushes, when they stand end to end.

The 1900 B.A. Meeting.—A large meeting of Bradford gentlemen was held on Tuesday at the Town Hall, in response to a circular issued by the Mayor, for the purpose of considering a proposal from the Bradford Philosophical Society that the British Association should be asked to hold its annual gathering in the city in 1900. The next two meetings of the association will be held at Bristol and Dover respectively, while Glasgow will be the *venue* in 1901. The Bradford Philosophical Society has already approached the association on the subject, and it is considered probable that the city will be favoured with a visit. The last time the association held a meeting at Bradford was in 1873. It was suggested that a guarantee fund of £2,000 should be raised. A large and representative executive committee was appointed.

Electric Welding.—A lecture was given at Finsbury Technical College, on Monday, March 7th, by Mr. Reginald J. Wallis-Jones, A.M.I.C.E., M.I.E.E., on "Electric Welding." The various systems in use, such as the Benardos, Zerena, Coffin, "Voltex," Hoho-Lagrange (hydro-electro-thermic), and the Thomson (incandescence system), were described and illustrated by experiments and lantern slides. Many unique and interesting samples of "snap" or rapid electric welding (Thomson process) as applied to the manufacture of cycle parts, &c., were shown. Apparatus and samples were lent by the Electric Metal Working Syndicate and the Electric Welding Company, Limited.

Electrical Engineers Royal Engineers Volunteers.—By kind permission of Colonel Josselyn the corps has been able to commence squad drills at the head-quarters of the 1st Middlesex Royal Engineers Volunteers in College Street, Chelsea. Technical drills, which count towards efficiency, will be commenced at the end of the present week.

Mishap at Yarmouth.—With reference to the mishap which occurred at the Yarmouth electricity works on Saturday last, we learn from Mr. A. W. Ranken, the borough electrical engineer, that the breakdown was due to sudden priming from the boilers, which blew off the steam tops and H.P. cylinders from two engines before they could be reached. The public lighting plant was only saved in time by shutting down. Supply to public lamps, and part of the private lighting, was resumed in the course of an hour, and since 11 p.m. the same night the plant has been running as usual.

Power Transmission at 50,000 Volts.—A trans-Atlantic contemporary says that a trial was recently made for a period of two weeks of transmission at 50,000 volts from the water-power plant at Telluride, Col., to the Gold King Stamping Mills there. The original transmission plant, which consisted of a single-phase 3,000-volt alternator with direct transmission to a synchronous motor three miles, has been replaced by a three-phase transmission with step-up and step-down transformers, and while the change was being made, the experiment of transmitting at 50,000 three-phase alternating current was tried. The transformers used were those now employed on the three-phase transmission there, the transformers being arranged to give a number of different voltages from 50,000 down, according to the way they are connected. No accidents occurred during the fortnight. The line consisted of galvanised iron telegraph wires supported on glass insulators. It is stated that it was found that the self-induction afforded by the iron wire had a beneficial effect in counteracting the capacity of the line. The experiment was not continued for a longer time because the rainy season came on, and proper provisions against lightning were not at hand. The transmission line is three miles long, and runs up a steep mountain side and over a very wild country.

The Northampton Institute.—The Lord Mayor and Sheriffs have kindly consented to pay a State visit to this Institute on the 18th inst., for the purpose of inspecting it and formally declaring it open. It is interesting to note that the buildings and equipment have up to the present cost over £80,000, and the expenditure upon the latter is not yet complete. In addition, the land, over 1¼ acres, generously given by the late Marquis of Northampton is estimated to be worth not less than £25,000. The Institute is a branch of the City Polytechnic, and is situated in one the busiest parts of the Metropolis, immediately north of the City boundary.

Edison and his Interviewers.—So many absurd interviews alleged to have been held with Mr. T. A. Edison have appeared in the newspapers and other journals, both on this side of the Atlantic and in America, that it is only just to that gentleman to say that in a communication to the *New York Sun* he protests "against the many articles appearing in the sensational papers . . . . . purporting to be interviews with me about wonderful inventions and discoveries made or to be made by myself. Scarcely a single one is authentic, and the statements are the inventions of the reporter."

Baden.—The new clubhouse provided by Messrs. Brown, Boveri & Co. for their technical and commercial staff was opened on the 8th inst. The firm has purchased the old Café Schwert, and placed it gratis at the disposal of the club. The reading room contains about 40 daily, weekly, and monthly papers in various languages, including the Electrical Review, the *Standard*, *Punch*, and others. A restaurant is also provided in connection with the club. The picturesque old building is familiar to all visitors to Baden, and it is interesting to note that it is, in a measure, the birthplace of the firm of Brown, Boveri & Co., as the temporary offices were situated there before the erection of the present buildings.

Lectures.—On 2nd inst., at the Merchant Venturers' Technical College, Bristol, Prof. J. Wertheimer repeated his lecture on "Wireless Telegraphy."

Before the Architectural Section of the Philosophical Society of Glasgow, Mr. W. Arnot recently lectured on "The Distribution of Electricity in the House."

Mr. W. B. Hird, B.A., read a paper on "Electric Transmission of Power" before the Salford Technical College Scientific Society, on 26th ult.

Mr. Richard Kerr, F.G.S., delivered a lecture on "Wireless Telegraphy" at the Geographical Institute, Newcastle, on 1st inst.

Mr. G. L. Addenbrooke, M.I.E.E., read a paper on Saturday evening on "Electrical Power Supply from Central Stations" to the members of the South Staffordshire Institute of Iron and Steel Works Managers, at Dudley.

Appointment.—Mr. A. E. Briscoe, head of the Physics and Electrical Department at Battersea Polytechnic, has been appointed by the West Ham Town Council principal of the new Technical Institute now building in Roman Road, Stratford.

Obituary.—We regret to hear of the death of Mr. Radcliffe Sanders, of the Penarth firm of electricians.

We also regret to announce the death of Mr. John Main, which took place on Wednesday last, at the comparatively early age of 51. Mr. Main was probably unknown to the younger generation of electrical engineers, but to the pioneers of the arc lighting industry his name is familiar as one of the joint inventors of the Fyfe-Main lamp.

Will.—The *City Press* says that the will has been proved of Major Alexander Wood, of Dar-el-Saleem, Abbey Wood, for many years the managing director of the Western and Brazilian Telegraph Company, the value of the personal estate being £11,704 17s. 8d. gross, and £7,221 13s. 8d. nett.

Battersea Vestry v. County of London and Brush Company.—In this case, which came before Sir Francis Jeune in the Chancery Division on Wednesday and Thursday, the plaintiffs claimed that the defendants had no right to open Trinity Road, Battersea, and lay electric mains therein, as they had done. The chief question in dispute was whether that portion of the road was in Wandsworth or Battersea parish. For the defence it was contended that this was not a case for a mandatory injunction, even if defendants were in default. The Judge thought the company might very well recognise the plaintiffs' right and take a license from them. The case was adjourned for a month to enable his Lordship's opinion to be submitted to the Vestry.

FORTHCOMING EVENTS.

1898.

Friday, March 11th, at 5 p.m.—Physical Society at the rooms of the Chemical Society, Burlington House. Agenda:—(1) "On Dynamical Illustrations of certain Optical Phenomena," by Prof. J. D. Everett, F.R.S.; (2) "On Properties of Liquid Mixtures," by R. A. Lehfeldt.

Saturday, March 12th, at 7.30 p.m.—At the Westminster Palace Hotel. *Conversazione* of the Institution of Junior Engineers.

At 10.30 a.m.—Institution of Electrical Engineers. Students' visit to the stations of the Metropolitan Electric Supply Company. Applications to join the party should be made at once to the Students' Hon. Sec. (Mr. S. Grant, 28, St. Mary Abbot's Terrace, W.).

Monday, March 14th, at 8 p.m.—The Northern Society of Electrical Engineers, at the Palatine Hotel, Hunt's Bank, Manchester. Paper on "The Practical Operation of Multiphase Currents" will be read by Mr. T. Hawkins, member.

Tuesday, March 15th, at 8 p.m.—The Institution of Civil Engineers "Calcium Carbide and Acetylene," by Henry Fowler, Assoc.M.Inst.C.E.

Wednesday, March 16th.—The Institution of Electrical Engineers. Students' meeting at 7.30 p.m. A paper will be read on "Polyphase Motors," by E. E. Tasker, student.

Latest date for Watford District Council electric lighting tenders.

Thursday, March 17th, at 8 p.m.—Chemical Society, Burlington House. Papers to be read:—"The Reduction of Bromic Acid and the Law of Mass Action," Winifred Judson, B.Sc. and J. Wallace Walker, M.A., Ph.D.; "The Action of Ferric Chloride on the Ethereal Salts of Ketone Acids," R. S. Morell, M.A., Ph.D. and J. M. Crofts, B.A., Ph.D.; "Note on the Volatility of Sulphur," T. C. Porter; "Action of Ammonia and Substituted Ammonias on Acetylurethane," George Young, Ph.D. and Ernest Clark.

At 3 o'clock.—Royal Institution. Prof. J. A. Fleming, M.A., D.Sc., F.R.S., M.R.I., on "Recent Researches in Magnetism and Diamagnetism," Lecture III. (The Tyndall Lectures).

At 11 a.m.—The Institution of Civil Engineers. Students' visit to the ventilating, heating, lighting, and drainage arrangements of the Houses of Parliament.

Latest date for Wallasey District Council electric lighting tenders.

Friday, March 18th.—State visit of the Northampton Institute for the purpose of inspecting it and formally declaring it open.

Saturday, March 19th.—Students' visit to the works of Messrs. Easton, Anderson and Goolden, Limited, Erith.

Thursday, March 24th, at 8 p.m.—The Institution of Electrical Engineers. "Cost of Generation and Distribution of Electrical Energy," by R. Hammond, member.

NEW COMPANIES REGISTERED.

North London Electric Supply Company, Limited (56,275).—Registered March 1st, with capital £100 in £1 shares, to carry on the business of electricians, electrical engineers, suppliers of electricity, and electrical apparatus manufacturers. The subscribers (with one share each) are:—F. J. Leslie, 15, Union Court, Liverpool, solicitor; A. E. Haptie, 5, Durham Road, Seaforth, Liverpool, cashier; F. W. Lintern, 104, Northbrook Street, Liverpool, clerk; J. Atherton, Singleton, Huyton, Lancashire, manufacturer; W. M. M. Forwood, 15, Union Court, Liverpool, solicitor; C. O. Grindrod, 11, Knowsley Road, Rock Ferry, gentleman; A. Buckley, 8, York Road, Seacombe, Cheshire, clerk. Registered without articles of association by T. T. Hull, 22, Chancery Lane, W.C.

Edison-Bell Consolidated Phonograph Company, Limited (56,304).—Registered March 2nd with capital £110,000, in 10,000 preference shares of £10 each and 10,000 ordinary shares of £1 each, to acquire the business of the Edison-Bell Phonograph Corporation, Limited, to adopt a certain agreement, and to manufacture, sell, let on hire, and deal in phonographs, graphophones, telephones, phonogram-cylinders, motors, batteries, and electrical apparatus. The subscribers (with one share each) are:—Earl of Denbigh, Newnham Paddox, Lutterworth; Lord Farquhar, 7, Grosvenor Square, W.; M. Van Raalte, 22, Austin Friars, E.C., merchant; E. F. Coates, 99, Gresham Street, E.C., stockbroker; Count de Torre Diaz, 41, Moorgate Street, E.C., merchant; S. J. Waring, jun., 28, Park Lane, W., manufacturer; W. A. Smith, 6, Hanover Street, Glasgow, merchant. The number of directors is not to be less than three nor more than eight; the first are—The Right Hon. the Earl of Denbigh, J. Annan, Sir W. H. Q. Jones, R. C. Wyatt, W. A. Smith and S. F. Moriarty; qualification, £500; remuneration, £300 each per annum (£400 each for the chairman and deputy chairman), and a percentage of the profits. Registered by Ashurst & Co., 17, Throgmorton Avenue, E.C.

OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

Westinghouse Electric Company, Limited (29,334).—This company's annual return was filed on January 13th. The capital is £600,000 in £10 shares (30,000 preference). 18,955 preference and 27,500 ordinary shares have been taken up, and 15,800 of the former and all the latter have been issued as fully paid. £10 per share has been called and paid on the remaining 3,155 shares.

Ventnor Electric Light Company, Limited (53,823).—This company's statutory return was filed on November 11th, when seven shares were taken up out of a capital of £10,000 in £5 shares. No calls have as yet been made.

Crystal Electric Lamp Company, Limited (53,651).—This company's statutory return was filed on January 3rd. The capital is £10,000 in £1 shares, of which 6,667 shares have been taken up. 1,667 are considered as paid, and £5,000 has been received.

Crystal Palace District Electric Supply Company, Limited (18,532).—The registered office of this company was removed on February 4th to Dashwood House, 9, New Broad Street, London, E.C.

Municipal Electric Light and Power Corporation, Limited (29,091).—This company's annual return was filed on February 12th. The capital is £25,000 in 2,490 £10 ordinary, and 100 £1 founders' shares. 37 ordinary and 30 founders' shares have been taken up, and £400 has been paid.

Morley Electrical Engineering Company, Limited (52,358).—This company's statutory return was filed on February 9th, when 1,024 shares were taken up out of a capital of £5,000 in £1 shares and paid for in full.

CITY NOTES.

Directors' Fees. It is stated that at the meeting of the County of London and Brush Provincial Electric Lighting Company to be held next Monday, a resolution will be proposed to raise the remuneration of the directors from £1,000, as fixed in the articles of association, to £2,000 for 1898, £2,500 for 1899, and £3,000 a year afterwards.

We should scarcely think the ordinary shareholders will feel in the mood to agree to the somewhat premature demands of the board; indeed, the shareholders would be amply justified in resisting any attempts to double the directors' fees until a dividend on the ordinary shares has been paid.

Westminster Electric Lighting Company. The principal features of the year's business of this company have been already set forth in these columns, and little more remains to be done, except to give an analysis of costs for the year. The increase in the cost of coal is mainly attributable to important alterations in plant, which have caused a slight break in the economical *régime* that has hitherto been a characteristic feature of the system.

The following table gives the cost per unit:—

	1897.	1896.
Total capital expended	£560,388	£478,870
Number of units sold	4,416,877	3,503,054
Number of lamps connected	290,561	249,318
Revenue from sale of current	£100,561	£81,214
Net revenue	£49,585	£40,431
Average price obtained per unit	5·46d.	5·5d.

Cost of production.	£		Per unit.	1896.
Coal	11,450		·62d.	·54d.
Oil, waste, water and engine room stores	1,737		·09d.	·10d.
Salaries and wages at generating station	7,663		·42d.	·45d.
Repairs and maintenance of buildings, engines, boilers, dynamos, &c.	3,648	Works' cost 1·33d.	·20d.	·29d.
Rent, Rates and taxes	5,002		·27d.	·25d.
Management expenses, directors' remuneration, salaries of managing engineer, secretary, clerks, &c., stationery and printing, general establishment charges, auditors, law charges, and insurance	9,249		·50d.	·56d.
Total	£238,749		2·10d.	2·19d.

Not included in above.	
Repairs and maintenance of meters.	£1,183
Wages of meter readers	745
Sinking fund and depreciation account	15,290
Loss on coal	81
Supplying steam	1,559
Expenses of founders' shares	172

Revenue.	£	s.	d.	Average price obtained per unit.
By sale of current	100,561	0	0	—
Meter rents, &c.	4,343	0	0	5·46d.
Supply of steam	2,392	0	0	—
Transfer fees	69	0	0	—
Total	£107,365	0	0	5·46d.

Total cost per unit (exclusive of depreciation and renewal accounts), 2·10d.; works' cost, 1·33d.

London Electrical Omnibus Company, Limited.

An extraordinary general meeting of this company was held last Friday at Winchester House, E.C., to receive the report of a committee which was appointed at the annual meeting of the company, held on December 30th, 1897. Major Flood Page presided, and called upon the chairman of the committee (Lieut.-Colonel Turnbull) to read the report of the committee, which was as follows:—

1. The committee have to report that they held a meeting on December 30th, 1897, and wrote on the following day to the board requesting the chairman to name a day for consultation. It was arranged that all joint meetings should be held at the office of the company, and the committee have received most courteous treatment from the chairman and members of the board, and information has been placed before the committee upon all questions raised.

2. At the first joint meeting a letter was submitted by the chairman of the board from Mr. Scrimgeour, intimating that as he would be out of London for some weeks, he would suggest that Mr. J. S. Thomson (who held his proxy) might be allowed to represent him on the committee. This was unanimously agreed to, and the committee hope the shareholders will endorse this decision.

The Present Position of the Company.

3. The first business discussed was the company's present unsatisfactory position, which, in the opinion of the committee, results from the following causes:—

(*a*) By the board having gone to allotment on too small a firmly-subscribed capital.

(*b*) By the payment to the vendors of £6,163 10s. in cash, when the company had such a very small available working capital.

(*c*) By the board having made an agreement on July 29th, 1896, with Mr. Marshall, one of the vendors, who was also a director of the company, that only one call of equal to 2s. per share should be made prior to July 31st, 1897. This agreement deprived the company of the power to raise the capital necessary to work the business.

(*d*) By the loss of capital—firstly, through the failure of Mr. Marshall and his associates ultimately to pay their calls, amounting to £9,737 10s., and secondly, to that of other shareholders, amounting to £5,696 19s., making a total deficiency of working capital of £15,434 9s.

(*e*) By the excessive expenditure upon general charges, as shown in the annual report; a portion of this may, however, have been indispensable in the establishing of this new industry.

(*f*) By the large expenditure in connection with the development of the Sola accumulator.

4. The above are the reasons why this company has not succeeded as it ought; but, with an increased working capital of not less than £15,000, and under economical and careful management, expending said capital in building and properly equipping omnibuses, the committee are satisfied the company has a splendid future before it, with a large earning capacity. Provided the above capital is secured to work the Ward system and Schanschieff Sola accumulator agreements, which are both valuable, the position of the company is much better than was represented to the public previous to the annual general meeting.

5. Mr. Ward has agreed with the board and committee to extend his licenses to the whole of the United Kingdom; he to be paid 10 per cent. in cash or shares on any gross amount the company may receive from the sale of the same in the United Kingdom outside of England; the company already possessing the licenses for England; the company also to have the benefit of any and all improvements Mr. Ward may make in relation to electric accumulator traction in omnibuses, cabs, stage coaches, and other public vehicles other than vehicles used on tramways.

6. Mr. Schanschieff's agreement conveys the exclusive right to use his patents for accumulators for omnibuses and cabs for London, with the additional privilege of granting sub-licenses for all public carriages, excepting tramways, for all England, and a right to use any improvements and discoveries that may be secured by the patentee, provided the company pays cost of securing the patents. Also, the patentee undertakes to supply accumulators for 300 omnibuses at actual cost, and, should the company decide not to manufacture accumulators, to supply all future orders at a royalty to be fixed by arbitration, the price not to exceed what is usually paid to other accumulator companies. Further arrangements can be made with the patentee to mutual advantage.

7. Mr. Spagnoletti attended one of the meetings, and expressed his opinion that the "Sola accumulator was most suitable for street traction, because it was lighter and cheaper than the average accumulator, and more economical to manufacture and work."

8. The committee requested the board to make a practical test of the running of the omnibus, resulting in a trial made on the 5th inst. The entire arrangements for this test were made under the direction of the board, who requested Mr. Spagnoletti and Mr. Schanschieff to take observations, and Mr. Ward to act as engineer. The omnibus carried 17 passengers, and ran out to Hammersmith Broadway from Trafalgar Square and back to Whitehall, a distance of 14 miles, going and returning by circuitous routes. On the outward journey the route lay up Haymarket, one of the steepest grades in London, and the omnibus maintained a uniform rate of speed on this grade. The steering was perfect in every respect, and the control in starting and stopping was thoroughly successful, the omnibus threading its way through the crowded traffic with perfect facility. Mr. Spagnoletti concludes his report thus:—

"The result of this trial trip I consider most encouraging, and very satisfactory indeed."

9. The committee find a contract is in existence with the Electric Street Car Manufacturing Syndicate, Limited, of Wolverhampton, its main object being the building of suitable omnibuses in an expeditious manner for this company. Provided these are secured on advantageous terms, this contract should prove to be to the interests of the company.

10. The committee, having carefully examined the articles of association, are of opinion that these should be suitably amended.

11. *Ordinary Stock* (*unissued*).—The company has at present at its disposal 119,993 shares ordinary stock unissued.

12. This issue is 80,000 shares of £1 each; these were all given to the vendors. The committee recommend that, provided the consent of the holders of the ordinary stock is secured, some satisfactory arrangement should be made with the deferred shareholders which would have the effect of reducing the capital stock of the company very materially. This, in conjunction with the securing of the additional capital, would be an important factor in the future prosperity of the company.

13. In the meanwhile this company has secured a prominent lead in the great question of electric traction for omnibuses, &c., and the committee feel assured that within a very short space of time this company's method of accumulator traction will entirely supersede that of horse traction. The committee have gone into facts and figures and given careful consideration to the probable results from an investor's point of view, and are satisfied that if properly-equipped omnibuses are placed on good thoroughfares in London and elsewhere, with regular services, the returns will be satisfactory on money invested, and will bear out the figures, as to profits, given in the original prospectus.

14 A reduction of expenditure is necessary, and towards this it has been proposed, by the directors themselves, that they should be entitled to only two-thirds of the fees fixed in the articles of association until such time as the company has paid an annual dividend of 7 per cent.

15. Mr. Ward has voluntarily reduced his annual salary one-half until the company is able to pay a 7 per cent. annual dividend to its shareholders, when he may resume his former salary, provided the said dividend is arrived at within the limit of his agreement. Mr. Ward has also relinquished his seat at the board.

16. It has been unanimously decided by the board and committee jointly, that a sum of *at least* £15,000 working capital is required for the immediate development of the company's business. It is proposed to construct 12 omnibuses, and place them on a desirable route, or routes, to be decided. It is estimated that these omnibuses will cost, with complete equipment, the sum of about £9,000, leaving a balance for fixed charges, omnibus stabling, wages, &c., of about £6,000.

17. In the event of providing a station and electrical appliances, so that this company might supply its own electricity, it is estimated that a further sum of about £5,000 would be required. Though arrangements can at present be made to purchase electricity on fairly reasonable terms, it is thought advisable that this matter should be taken into consideration as soon as the necessary capital is available.

18. The immediate appointment of an assistant engineer is absolutely necessary; this will receive the board's attention.

19. The company has the right to dispose of the forfeited shares upon which 10s. has already been paid, or credited as paid. This should prove a valuable asset, and the committee recommend that these shares should be offered: (1) To the shareholders who have defaulted. If so taken up the company would receive the sum of over £15,000; and (2) To the present shareholders as fully-paid shares for the sum of 10s. each, which would yield the sum of £15,935; and (3) in block to any person or persons who would be willing to purchase at a price to be named, or who would advance a sum sufficient for the company's immediate requirements. Provided the amount required is realised from the forfeited shares, there will remain 119,993 unissued shares of ordinary stock, which the proposed development under the expenditure of the £15,000, should also become an asset of considerable value to the company.

20. The committee feel assured that the future prosperity of the company, carried out on the proposed lines, will lead to great financial success; and trust this policy will be heartily endorsed by the shareholders.

In proposing the adoption of the committee's report Col. Turnbull said there had been mistakes of judgment on the part of the board, but they had had great difficulties to contend with, on account of going to allotment on too small a capital, and by reason of shareholders not paying their calls. More money had been probably spent on the Sola accumulator than the shareholders might think ought to have been done, but it had been done with the best objects.

Mr. Condict, a member of the committee, seconded the report, and referred in terms of praise to the Sola accumulator.

The report of the committee was then accepted, and it was agreed to remunerate the services of the committee by 100 guineas.

The Hove Electric Lighting Company, Limited.

Col. Filgate presided at the annual meeting of this company, held at Cannon Street Hotel, on Monday, and congratulated the shareholders on the position the company had attained. The capital expenditure had increased from £62,022 at the end of 1896, to £66,896, at the close of 1897, or by £4,874. Of this increase, £3,764 had been expended on mains, and £887 on meters. The demand for the supply of electric current in new streets, necessitated increasing the section of copper in the mains and feeders, the construction of about 2½ miles of new mains from all of which they hoped to realise a fair return. The demand for new mains was a satisfactory feature in their business, and they had every reason to believe that this demand would continue. Since the close of the year they had sanctioned further additions to their system of about 1½ miles of mains. To cope with the increasing demand on the works for current, they ordered a new 350 H.P. Willans-Crompton set for delivery early in the Autumn, but owing to the engineering strike and other causes, this set had only recently been delivered. Owing to the non-delivery of the new set, they were somewhat anxious as to their capability of meeting the heavy load during December, but the plant worked satisfactorily, and met the demand without any hitch. With this new set the power of the plant would be increased from 750 H.P. to 1,100 H.P. To meet the expenditure they had to incur, they determined to ask the shareholders' approval to increase the share capital by 2,000 shares of £5 each. 1,000 of these they proposed to issue at an early date, and to offer them to the proprietors *pro rata* at a premium. As the shares stood well in the market, they had no doubt that the issue would be a success. They further took advantage of this opportunity to ask the shareholders to increase the borrowing powers from £25,000 to £50,000. The year's working showed a satisfactory result, and that notwithstanding the large reduction they had made in the prices charged to customers for current, amounting to about 20 per cent. That reduction has no doubt increased the number of customers and the consumption of current. The number of customers had grown from 270 at the end of 1895, to 314 at the end of 1896, and to 397 at the end of 1897. The number of lamps attached to the system at the same dates were the equivalent of 18,298, 21,914, and 27,777 respectively. The number of units delivered to customers in the three years was, in 1895, 162,428; in 1896, 200,562; and in 1897, 268,243. Those figures showed the healthy and progressive nature of their business. The gross revenue for 1897 amounted to £7,269, compared with £6,518 in 1896, an increase of £751, while the working expenses stand at £3,667, against £3,404 in the previous year, an increase of £263. Considering the large increase in units delivered to customers, which amounted to 34 per cent., they would agree with him that the work has been conducted economically, which he must attribute to the care bestowed on the business by Mr. C. B. Smith, the resident engineer, at Hove, to the good work done by Mr. Reeves, the secretary, at head-quarters, and to the thoroughly satisfactory machinery supplied by Messrs. Crompton and Co., Limited, which has worked in a highly satisfactory manner. After providing interest payable on debentures and loans for the year 1897, income-tax, and interim dividend, at the rate of 4 per cent. per annum paid last October, they had a balance left of £2,092 7s. 11d. to deal with. They proposed, in the first place, to write off £150 from the amount standing in the capital account under "preliminary expenses," reducing the balance under this head to £1,200; to set aside £600 to the credit of the reserve fund; to pay a final dividend for the half-year at the rate of 6 per cent. per annum on the capital of the company, making, with the interim dividend paid in October, 5 per cent. per annum for the year, and to carry forward the balance, £218 7s. 2d., to the current year. Speaking of their prospects, the units delivered to customers from January 1st, compared with last year, showed an increase of nearly 30 per cent. The Hove Commissioners had again taken up the question of increasing the light in the streets of Hove, but were apparently debating as to whether the increased light which the public was demanding should take the shape of the electric light or an increased consumption of gas. They had made the Commissioners numerous proposals during the last five years for the supply of current for public lighting, but none of them had found favour with the Commissioners. At their request, they made a further and very liberal offer some two months ago, but had as yet received no communication regarding it.

The accounts were then adopted.

The House-to-House Electric Light Supply Company, Limited.

The directors' report states that the revenue account shows a credit balance of £12,033 4s. 11d., which, with the balance of £43 12s. 6d. brought forward, and £177 6s. 8d. dividends and balance of interest received, makes a total of £12,254 4s. 1d. After deducting £2,250 for interest on debenture stock paid and accrued, and £1,403 19s. 2d. for interim dividend paid on the 7 per cent. cumulative preference shares, the directors recommend that the sum remaining, viz., £8,600 4s. 11d., be dealt with as follows:—

		£	s.	d.
To credit of depreciation account	...	3,000	0	0
To payment of the remainder of dividend to December 31st, 1897, on the 7 per cent. cumulative preference shares	...	1,750	0	0
In reduction of preliminary expenses account	...	1,391	4	8
To payment of a dividend on the ordinary shares for the year at 4 per cent.	...	2,232	14	5
And that the balance of ... ... be carried forward to the next account.	...	226	5	10
Total	...	£8,600	4	11

The sums of £11,926 received as premiums on the last issue of shares and of £1,097 6s., profit on sale of 300 Yorkshire House-to-House shares have been applied in extinction of the balance of preliminary expenses account and construction business development account.

The following Table shows the progress of the company's electric lighting business since 1890:—

Year.	Equivalent of 35 watt (8-C.P.) lamps connected.	Increase in 35 watt (8-C.P.) lamps.	No. of houses connected.	Gross receipts.			Expenditure.			Net receipts.		
				£	s.	d.	£	s.	d.	£	s.	d.
1890	18,665	9,145	248	5,010	9	2	4,624	6	5	386	2	9
1891	19,388	5,723	373	8,328	8	11	6,077	14	10	2,250	9	1
1892	23,700	4,312	471	10,688	18	6	7,851	19	6	2,836	19	0
1893	28,429	4,729	599	12,068	10	10	7,832	6	8	4,231	4	2
1894	35,[illegible]58	7,429	755	13,695	11	8	7,431	16	8	6,263	15	0
1895	44,162	8,304	982	15,394	16	11	8,554	0	10	6,840	16	1
1896	55,265	11,103	1,164	17,442	6	5	8,410	8	4	9,031	18	1
1897	66,364	11,099	1,416	20,810	10	1	8,777	5	2	12,033	4	11

The increase in the number of lights connected during 1897 was equivalent to 11,099 8-candle-power (35 watt) lamps. The revenue from electricity has increased by £3,200 12s. 6d., while the expenses have increased £366 16s. 10d.

Additions and alterations to the plant and mains have been made, at a cost of £24,326 16s., and the expenditure for 1898 is estimated at £28,000. This outlay will be provided by the proceeds of the ordinary and preference shares issued under the agreement with the holders of founders' shares.

The Leeds and London Electrical Engineering Company, Limited, having resolved upon voluntary liquidation, gave notice to determine the agreement with this company. The directors have decided, in view of the consequent unsatisfactory position of this asset, to write off the whole, as stated. The relations between the two companies are receiving the careful consideration of the board.

A portion of the capital expenditure in recent years having been incurred in superseding earlier and less efficient plant, it will be necessary to make proportionately larger annual contributions to depreciation account than hitherto, in order to preserve the capital intact at the expiry of the concession. On the other hand, the revenue account will, in future, be relieved by the extinction of preliminary expenses now effected. The agreement with the holders of the founders' shares, which was passed by the shareholders, having received the approval of the High Court, has now been carried out. During the year a further 1,661 ordinary and 3,332 7 per cent. preference shares have been issued.

Mr. H. R. Beeton and Mr. R. A. Germaine retire from the board by rotation, and, being eligible, offer themselves for re-election. Messrs. Miall, Wilkins, Randall & Co., the auditors of the company, offer themselves for re-election.

Kensington and Knightsbridge Electric Lighting Company, Limited.

Mr. Granville R. Ryder presided on Thursday last week over the eleventh ordinary general meeting of the above company, held at 1, Great George Street, Westminster.

In moving the adoption of the report, the Chairman said the shareholders would observe that the form of accounts adopted on the present occasion was different from what they had been used to hitherto. The form in which they were put that day was the one required by the Board of Trade, and up to the present they had had practically to prepare two sets of accounts—one in the old form they used to have, and one according to the Board of Trade. Personally, he must say that he preferred their old form of accounts, as it set out things more clearly before them than those voluminous and somewhat pedantic figures. However, the point was not how the accounts were set out, but what was in them. He thought it was very gratifying to them to be able to put before the shareholders so satisfactory a statement. During the year the number of houses and shops which had taken the light had increased by 295, against the preceding year, whereas in 1896 the increase was only 216, as against the year preceding that. That was very satisfactory. On the other hand, the actual increase of lamps for the year was not so great as it was the year before. In fact, last year it was only 18,000 lamps as against 25,000 in the year before. But there was ample evidence that the district as a whole was taking more electric light, because, as a matter of fact, the actual number of units of electricity which had been taken by the district during the year as compared with the year before showed an additional increase of nearly 100,000 units—that was an increase of 353,000 units as against 285,000 units. With regard to the capital account, they would observe that the amount of increased capital which had been issued during the year was £11,060 of 4 per cent. debenture stock and £10,000 of the 5 per cent. second preference shares, that had been issued at a premium which produced within the year £2,079. With regard to that premium, £558 of it had been used to wipe out the remainder of the cost of the conversion of the debenture stock two or three years ago. The rest—£1,521—had been written off against the Kensington Court purchase account, which did stand at £13,000, and was, therefore, now reduced to about £11,500. The next point was with regard to the renewal account. They would observe that the sum of £8,061 had been paid to that account after paying for the maintenance for the year of the plant of all kinds, including buildings and everything else, at a cost of £3,150. While the sum of £8,061 might possibly be thought to be rather too large a sum to put to that account in one year, yet the best men competent to advise us on the subject, considered the point was to make that particular fund a strong one, and so give to the company all the stability possible. When they came to consider how fragile and short-lived a good deal of the electrical plant was, and how necessary it was that they should be in a position to take advantage of all improvements in electrical science which came out, it was absolutely necessary that such a fund as that should always exist in the case of a company such as theirs. With regard to the number of units sold during the year, the figures were very satisfactory. In 1896 the number of units of electricity sold was 1,514,729, and in 1897 the number was 1,898,362, an increase in the year of 383,633 units. It was satisfactory to find that the increase had been earned at an increased cost of £18,019, but at the same time the profits had increased from £34,371 to £41,681, and, therefore, they had earned the additional amount of £7,309. That showed that when they increased their output they decreased the cost, and so he hoped it would always go on. It must go on until the time came when they would have to go in for extensive new works, or for large additions to the existing works. These were the principal points to which he had to call their attention. One item of expenditure they would notice was always increasing—rates had increased by about £1,000, and, as far as they could judge, there was little chance of any diminution under that head. At one time it used to be considered that premises should be rated according to the burden they were to the parish. Now that was altered, and it seemed to be the custom to take the profits and charge on that, and what it came to practically was paying another income-tax.

Sir Frederick Bramwell seconded the motion.

A Shareholder asked how it was that the shares were not quoted on the Stock Exchange.

The Chairman said it would be a great advantage if they could get a quotation, and they were gradually working up to that. It was, however, necessary to have a certain proportion of share capital to debentures before they could get a quotation. It was a matter which the board had always in view.

The Shareholder said the amount carried to renewal account was equal to a dividend of 3 per cent. The chairman had referred to the fact they could continue to produce electricity at a cheaper rate until they had to enlarge the works. He would like to know how much longer it would be before the plant would be fully employed and lighting would have to extend?

Mr. Crompton said the plant was now up to the capacity which it was originally expected the district would take, and in all probability it would be fully utilised at that time next year, and after that there would have to be a very considerable increase. The probability of having to extend was due to the fact that the district had proved much better and richer than it was ever anticipated it would be. There were now many small tenements coming down which were being replaced by large flats, in which there would be a demand for electricity. It was quite possible they would have to increase their plant the year after next.

The report was then adopted.

The Chairman moved the confirmation of the interim dividend at the rate of 8 per cent. for the year and the declaration of a dividend at the rate of 12 per cent. for the year.

Mr. Hopkinson seconded the motion, and it was carried.

The retiring directors and auditors were re-elected, and a vote of thanks was passed to the board and the employés.

The Birmingham Electric Supply Company, Limited.

The directors report that the amount of net profit, including the balance of £1,042 15s. 6d. brought forward from last year, is £13,656 1s. 7d. Out of this sum, after placing £4,460 8s. 6d. to the credit of the depreciation reserve fund, the directors recommend the payment of a dividend of 5 per cent., absorbing £8,206 9s. 4d., and carrying forward a balance of £989 3s. 9d. The premiums obtained on the issue of the remaining portion of the company's capital amounted to £5,475 8s. 1d. Out of this the directors have added the sum of £3,366 17s. to the special reserve against provisional orders; with this addition the cost of the provisional orders, amounting to £4,027 4s. 8d., is now fully provided for. The balance of the above premium, amounting to £2,108 11s. 1d., has been carried to the general reserve fund. On making the above appropriations, the total reserves and undivided profits will amount to £22,536 16s. 6d.

There has been a steady increase in the company's business during the past year, the total number of 16-C.P. lamps, or their equivalent on order, December 31st, 1896, was 25,876, and on the same date in 1897 the number was 39,232. The additions since the close of the financial year have brought the number up to 40,707. The expenditure on capital account during the past year has been £35,250 9s. 4d.

Included in the capital expenditure during the past year are the completion of the works in connection with the new boilers at the Dale End station. The extension at the company's Water Street depôt in equipment of steam plant was completed in time for the winter's supply. Extensions have been made in the underground main system in various parts of the company's Parliamentary area.

The reductions in the company's charges for current, introduced in the early part of the year, although slightly decreasing the revenue per unit, have been amply justified by the greatly increased demand for current.

The company during the year have carried out, through the wiring department, a considerable number of installations for consumers from the company's supply system. Included in this work has been the entire installation of the General Hospital. Hitherto the working of the department has resulted in a surplus to the company's funds; the result, however, of last year's work has been a loss amounting to £558 2s. 3d., which has been written off the profits for the year. The directors have always looked upon this portion of the business as a necessary feeder to the company's system, and as the loss in question has been entirely due to the tedious and expensive nature of the work carried out at the General Hospital, such a loss is not likely to recur.

A large number of motors have been added to the system during the year, and the economy and convenience of electricity as a source of power are now generally recognised. In view of the continued increased output, orders have been placed for further engines and boilers for the Water Street depôt for completion by the end of the summer.

The capital of the company is now subscribed, paid up, and expended. As certain capital outlay is necessary during the year, a resolution will be submitted to the meeting to authorise the increase of the capital by the creation of 20,000 additional shares of £5 each, to be issued at the discretion of the board when necessary.

W. T. Glover & Co., Limited.

The prospectus of this company, registration of which we announced in our issue of February 25th, has been issued this week. The capital is £200,000, £100,000 5 per cent. cumulative preference shares, and £100,000 ordinary shares.

The business has been well known in the electrical world for some years, as that of manufacturers of insulated wires and cables, and enjoys a high reputation in these respects. The profits, although showing a trifling falling off for the last six months of 1897, have averaged for the past four years, over £14,000 per year.

It would appear that the company will acquire:—

	£	s.	d.
Land plant and machinery (according to Messrs. Wheatley Kirk, Price & Goulty's valuation)	43,733	5	4
Stock in trade on basis approved by Messrs. Wheatley Kirk, Price & Goulty... ...	49,436	17	6
Book debts (guaranteed by the vendors) ...	41,049	11	10
Sundry investments	1,205	9	4

or £135,425 4s. plus the value of the patents, goodwill, trade marks, &c. On the other hand, it will have to discharge the liabilities, £76,513 16s. 3d., it will, therefore, be in this position: £135,425 4s., less £76,513 16s. 3d., *i.e.*, £58,912. The value of the patents, goodwill, trade marks, &c., must, therefore, stand at about £91,088. In other words, the £150,000 (in shares and cash) plus the liabilities undertaken by the company, £76,513, or say £226,513, less the other assets valued at £135,425 as above = £91,088 the assumed value of the remaining assets (patents, goodwill, &c., &c.).

There are portions of the document regarding assets, liabilities, and vendors' consideration, so curiously worded that it would seem well-nigh impossible to criticise, but as the vendors will take all the ordinary shares (besides about one-third of the preference shares), there is no doubt that the holders of the remaining preference shares will obtain their 5 per cent. thereon.

The success of the issue is, we understand, well assured, and the undertaking has our best wishes for its continued prosperity.

Stock Exchange Notices.—The Stock Exchange Committee has ordered the following to be quoted in the Official List:—Waterloo and City Railway Company—540,000 ordinary stock, in lieu of the shares now quoted; West Coast of America Telegraph Company, Limited—30,008 shares of £2 10s. each fully paid, Nos. 1 to 30,000 and 53,001 to 53,008, and £150,000 4 per cent. debentures, Nos. 1 to 1,500, in lieu of the shares and debentures of the old company of the same name now quoted.

Applications have been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to—Babcock & Wilcox, Limited—A further issue of 8,000 ordinary shares; British Electric Traction Company, Limited—10,000 6 per cent. cumulative preference shares; Buenos Ayres and Belgrano Electric Tramways Company, Limited—"A" 6 per cent. cumulative preference shares; "B" 6 per cent. cumulative preference shares; and fully and partly-paid provisional certificates for 5 per cent. debenture stock; City and South London Railway Company—22,500 ordinary shares; St. James's and Pall Mall Electric Light Company, Limited—Further issue of 12,000 ordinary shares, Nos. 40,081 to 52,080. The Committee has been asked to allow Waterloo and City Railway Company—£540,000 ordinary stock, in lieu of the shares now quoted, to be quoted in the Official List.

Chelsea Electricity Supply Company.—The report for the year 1897 shows a balance available for distribution of £11,344, after payment of debenture stock interest, and placing £2,000 to the renewals fund. Dividends are recommended of 6 per cent. for the year on the preference shares and on the ordinary shares, carrying forward £1,652. £20,851 is added to the reserve fund from premiums, making the total of the reserve fund £36,717. Lamps connected total 96,638, an increase of 16,178 during the year.

British Insulated Wire Company.—After writing off £2,222 for depreciation, and £1,770 off preliminary expenses, the net profits for the eight months ended December 31st, were £17,754. A dividend at the rate of 15 per cent. per annum for the eight months is declared on the ordinary shares, £1,500 is transferred to patents and goodwill, and £129 carried forward.

Commercial Cable Company.—The directors have declared a quarterly dividend of $1\frac{3}{4}$ per cent. on the capital stock, payable on April 1st. The transfer books will be closed from the 21st inst., to April 2nd.

TRAFFIC RECEIPTS.

The Bristol Tramways and Carriage Company, Limited.—The receipts for the week ending March 4th, 1898, were £2,322 7s. 9d.; corresponding period, 1897, £2,101 18s. 1d.; increase, £220 9s. 8d.

The City and South London Railway Company.—The receipts for the week ending March 6th, 1898, were £1,089; week ending March 7th, 1897, £1,062; increase, £27; total receipts for half-year, 1898, £10,719; corresponding period, 1897, £10,775; decrease, £56.

The Dover Corporation Electric Tramways.—The receipts for the week ending February 26th, 1898, £100 12s. 10d.; total receipts, February 26th, 1898, £848 10s. 9d. Week ending March 5th, 1898, £99 15s.; total receipts to March 5th, 1898, £948 5s. 9d.

The Dublin Southern District (Electric) Tramways Company.—The receipts for week ending Friday, March 4th, 1898, were £378 16s. 7d.; corresponding week last year, £436 15s. 7d.; decrease, £57 19s.; passengers carried, 65,343; corresponding week last year, 69,824; aggregate to date, £3,594 9s. 4d.; aggregate to date last year, £3,913 7s. 6d.; decrease to date, £318 18s. 2d.; mileage, 8 miles.

The Liverpool Overhead Railway Company.—The receipts for the week ending March 6th, 1898, amounted to £1,364; corresponding week last year, £1,315; increase, £49.

The Western and Brazilian Telegraph Company, Limited.—The receipts for the week ending March 4th, 1898, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £8,099.

INSTITUTION OF ELECTRICAL ENGINEERS.

On the Manufacture of Lamps and other Apparatus for 200-Volt Circuits. By G. Binswanger Byng, Member. (Paper read February 24th, 1897.)

(*Concluded from page* 311.)

The possible current through four lamps on 200 volts, allowing 40 volts across each arc, is five times the normal; with five lamps on 230 volts, 7·5 times the normal; while with four lamps on 230 volts it is only 3·3 times the normal. Therefore, when 5-ampere lamps are used upon a 230-volt circuit, it is better to run four with steady long arcs than five with unsteady short arcs.

It is probable that the enclosed arc lamp will be brought into prominence in this direction, offering certainly many advantages; but I would point out that in practice the current cannot be largely increased, because of the frangibility of the enclosing envelope under an accession of temperature. If the cooling surface be increased so that the temperature of the gases surrounding the arc remain about the same, the efficiency of the lamp is considerably reduced.

Adverting to the manufacture and installing arc lamps, to meet the contingencies of the high voltage, we have to consider that, if the carbons run short, or the slides stick in one lamp, the other lamps close together, and the full voltage of the circuit is maintained across the shunt coil of that particular lamp. The possible troubles are that the shunt coil is burnt up, and that the carbon holders are damaged with the excessive flaring of the arc before it breaks.

It would hardly be practical to make magnets to stand such overload. Of course we can instal a cut-out and equivalent resistance to each lamp. But this expedient is very costly, and presents the further difficulties of finding suitable room near the lamp, or making it self-contained with the lamp, and of teaching the consumer that the full current can be used, although the lamps are not alight.

Some sort of cut-outs must be installed, and I am of opinion that there is a field for inventors in this direction. I will indicate how I have endeavoured to meet these difficulties.

If, as is generally the case, one pair of carbons burn at a greater rate than the others, the slide in that lamp will touch the stop first, and the stumps will burn away until the gap is wide enough to break the arc. I append a table showing the results of five trials.

Four 10-Ampere Lamps on 200-Volt Circuit.

+ *carbon* 18 *mm. cored*, − 11 *mm. solid*.

(1)	Arc flared and was extinguished at	...	1½ inches gap.
(2)	" " "	...	1 3/16 "
(3)	" " "	...	1 "
(4)	" " "	...	1¼ "
(5)	Current switched off when arc was at		2¼ "

In the first four trials the arc broke while flaring; that is to say, it travelled up the side of the carbon and ignited the loose dust, taking a spiral course, this course being continued until the length is too great for the voltage. The arc only leaves the point of the carbon when there is sufficient dust to maintain it, and counteract its increasing length; thus, when the supply of dust fails, the arc is extinguished before it can return to the points.

During Trial No. 5 the carbon became pointed, and the temperature rose to the extent of freeing the surface from dust, hence the arc did not leave the crater.

We may deduce from this the desirability of maintaining a considerable gap between the carbon-holders, exceeding even 3 inches. For absolute safety it is better to extinguish the arc automatically. Now an automatic switch is useless, because it is necessarily controlled by the potential across the lamp, and could not discriminate between the increased voltage caused by the carbons burning short and that caused by the extinction of a flare; and, since this may happen at any time, the arc could not be re-formed even when the carbons came together. The circuit, in fact, would be inert, and the arc would have to be re-established by hand.

An efficient cut-out must extinguish the arc, and simultaneously cut the shunt coil out of the circuit, the mechanism of the lamp also being free that the carbons may travel together. The shunt must on no account be cut out whilst the brake is on, since it could not then compensate the series coil and draw the carbons together.

For the protection of the shunt coil I have used a temperature fuse, made of an alloy with a melting point of 210° Fahr., and having sufficient sectional area to be independent of the amount of current likely to traverse it. The carbons could be held apart several minutes before fusion took place. Although a decided advantage was gained over a plain lead fuse, and the shunt coil was efficiently protected, the carbon-holders were not protected, and the fuse required renewing each time it became ruptured.

The chief difficulty in constructing an automatic "cut-in" and "cut-out" lies in the necessity for a rapid make or break, to save vibration and sparking. My system may be briefly explained, in that the arc is first short circuited through a shunt path, and so put out by reducing the voltage across the terminals. This short is then broken by a quick break switch, the same action reversing the shunt switch simultaneously, ready to fall upon its normal contact when the carbons touch, or are replenished. The mechanism is actuated by the main armature of the lamp, and the movements take place while the armature is below the feeding point, so as not to interfere with the working of the lamp.

You can see the actual working of this novel "cut-out" on the lamp which I show here.

Heating and Motors.

The effect of the increased pressure upon such applications of the house current as heating, cooking, &c., does not entail a sufficient alteration structurally or electrically to need an exhaustive description.

The resistances forming or causing the heating surfaces must be arranged to conform to the higher E.M.F. at the terminals, and it is mostly preferable to increase the length rather than decrease the diameter of the resistance wires; but this fact presents some difficulty in such articles where the space available is small. If the space is too limited, such apparatus can only be used in series, or in connection with an external resistance.

With motors, the greatest difficulty also lies in adopting the smaller sizes, say from $\frac{1}{12}$th H.P. to $\frac{1}{4}$th H.P., to suit the altered conditions of higher pressure. A certain structural alteration is doubtless necessary to arrange a new winding to produce the same efficiency as heretofore on a 100-volt circuit. In the larger sizes I am, in order to facilitate keeping stock, using a double or differential winding, which, when coupled in parallel, conforms to 100 volts pressure, and with the same winding in series, gives an equal efficiency on a normal load at the 200-volt pressure.

In reviewing the subject of higher voltage generally from a standpoint of *cost*, I am of opinion that sufficient time and experience, naturally resulting from an increased demand, will place the cost of most fittings for 200 volts within the margin of those of the lower voltage—except, perhaps, a few cases, among which I may instance incandescent lamps. These will necessarily always be more expensive, owing to increased cost in mounting of larger bulbs and extra supports, and also through increased time of exhaustion and percentage breakage.

But we must not overlook the fact that in the matter of wiring there must be a decided saving. The smaller sectional area of conductor per lamp employed, without the necessity of increased insulation, as also in a minor degree smaller connectors and contacts will, in all probability, compensate some other apparent disadvantages, and may bring the balance of cost in favour of the high voltage system.

I do not wish to bring the subject of cables and wires or wiring systems within the scope of my present paper; but I will only mention that, in my opinion, such matters as the establishment of revised wiring tables, the use of twin wires, the smallest gauge allowable for single lamps, the best and cheapest system of wiring for high-voltage supply, would be subjects well worthy of the immediate consideration of, and an interchange of opinion between, engineers and manufacturers.

TEST OF THE CHICAGO STORAGE BATTERY ROAD.*

(*Continued from page* 313.)

The coal had a theoretical evaporative power of 10·5 lbs. of water from and at 212° Fahr., and actually evaporated 6·6 lbs., giving for the efficiency of the furnace and boiler 62 86 per cent. This low efficiency is to be expected because of the boiler being 26 per cent. underloaded. The equivalent evaporation per pound of combustible was 8·22, so that the efficiency of the boiler alone is 78·3 per cent. The boiler then loses by radiation, convection, and through escaping gases 21·7 per cent. of the original heat units, while the furnace is to be charged with 15·44 per cent. of the lost heat, and 62·86 per cent. appears in the steam.

The economiser did not give satisfactory results on the tests shown. This is not the fault of the economiser, however, but is due rather to the unfavourable conditions under which it was installed and is operated. Several large cracks in the brickwork flue leading from the uptakes of the boilers to the economiser on the outside of the power house allow air to infiltrate to such an extent, that the flue gases are cooled fully 100° before reaching the economiser. In spite of this fact, however, the economiser, upon some of the other tests, effected an economy of 7 per cent., as figured from the gain in temperature of the feed-water. A graphical log of the boiler test made November 5th indicated a rise of 75 7° F. in the feed-water, due to the action of the economiser. This log also shows the amount of coal required for banking the fires over night. Upon this test, however, a larger amount of coal was burned in the boilers, and thus a greater amount of flue gases passed about the economiser pipes. During the latter part of the test on November 26th, the economiser was cut out of service.

The pumps used 14·36 per cent of the water evaporated by the boilers. The feed-water, however, was heated by the pump exhaust from a temperature of 97·4° F. to a temperature of 202° F., resulting in a gain of 9·25 per cent. The fuel, then, to be charged against the pumps is only 14 36 per cent., less 9·25 per cent., or 5·11 per cent. of the total fuel burned.

The test shows that the engines used 18 lbs. of steam per indicated horse-power. The conditions of the test were not favourable to either an accurate engine test, or to the most economical operation of the engines. The steam pressure was lower than it should have been, while the vacuum was but 24·25 inches. The engines were also overloaded during the entire run, and were operated at 363 instead of 380

revolutions per minute. The difference in the power developed by the two lines of cylinders is due to an improper adjustment of the cut-off on the north line. With a few changes there is no doubt but that a material improvement can be made in the duty of the engines.

The indicator cards taken with one engine operating one generator, running on open circuit, show a friction load of 32·26 I H.P. This is but 14·86 per cent. of the average, and is a very satisfactory figure.

The average efficiency between the horse-power developed in the cylinders and the electrical power delivered on the switchboard is shown to be 79·27 per cent., which is also satisfactory.

The commercial efficiency of the generator (including the leads to the switchboard) at this load is 78·27 ÷ 85·14, or 93·1 per cent., which is all that can be expected of a generator running 32 per cent. below its rated capacity.

The total station efficiency from coal pile to switchboard is 5·58 per cent. It may be of interest to compare this result with some other modern station. The Chicago Edison Company, in its Harrison Street station, produces electrical energy of ·3 of a cent per kilowatt-hour burning coal containing 13,000 British thermal units per pound, and costing delivered $1.05 per ton. The efficiency of that station, therefore, is (1·05 × 1,000 × 3 43 × 100) ÷ (·003 × 2,000 × 13,000), or 4·61 per cent. This indicates that the net efficiency of the plant tested is 20 per cent. better than that of the Edison station. The Edison station has an output of over 3,000 H.P., while the Englewood station has a maximum capacity of 500 H.P., which makes the comparison more striking.

The cost of fuel for a net kilowatt-hour on the switchboard is shown to be ·611 cent. This high price is to be explained, then, not by the inefficiency of the station, but by the fact that a high price is paid for a poor coal. With a more advantageous arrangement in the purchase of coal, there is no reason why this station should not develop a kilowatt-hour for less than ·3 cent.

(*To be continued.*)

THE KELVIN QUADRANT ELECTROMETER AS A WATTMETER AND VOLTMETER.

BY ERNEST WILSON.

Communicated by Dr. J. HOPKINSON, F.R.S., to the Royal Society Received January 11th—Read January 27th, 1898.

(*Concluded from page* 309.)

Experimental Results.

In making a thorough test of the electrometer as an alternate current wattmeter we have the following variables to deal with:—

1. The frequency of the alternate current.
2. The phase difference between current and potential, that is, between C and A or B.
3. The amplitude of C and A or B.
4. The shape or wave form of the curve of potential and current.

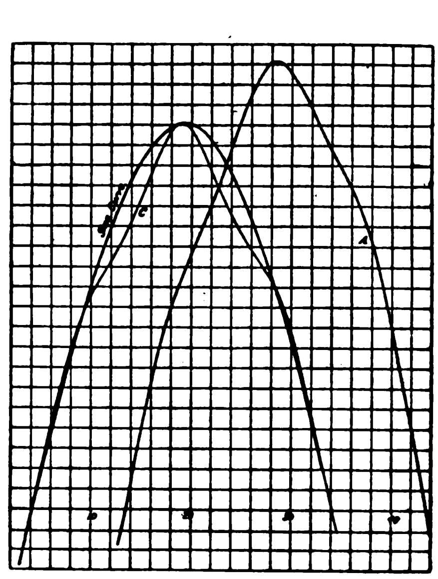

FIG. 3.

The results obtained are tabulated in Table II., and are divided into three groups (*a*) (*b*) (*c*). In group (*a*) two frequencies are given namely, 41 6 and 83 complete periods per second. The potential on the needle is constant at about 100 volts ($\sqrt{\text{mean}^2}$). The phase difference between potential and current and the current itself are each varied. When the phase difference is zero, it is only necessary to take the product of the $\sqrt{\text{mean}^2}$ values to deduce the watts,

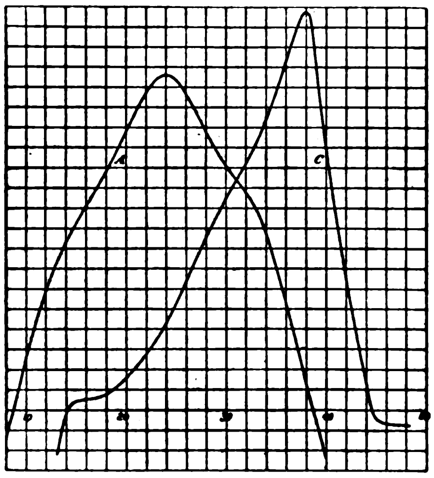

Fig. 4.

although in section (*b*) three instances are given in which for phase difference zero, the watts are deduced by both methods. The average watts per division given by section (*a*) are 17·00 for all angles of phase, leaving out the two values deduced by aid of the cosine law for angles of 30° and 60°. It will be seen that under the conditions

curve in fig. 1, that for high potentials on the needle the watts, per division of the scale, would diminish. This is found to be the case when the potential, C, is raised to 1,860 volts ($\sqrt{\text{mean}^2}$) for frequencies of 75 and 43. In section (*c*) the wave form is very much distorted. The curves of potential and current are plotted in fig. 4. The distortion of the potential curve, C, was brought about by placing a considerable non-inductive resistance in series with a choking coil, and taking potentials across the choking coil. The instrument under these conditions gives trustworthy results. The phase difference on one or two occasions was such that the curves indicated no work, the deflection under these conditions was zero.

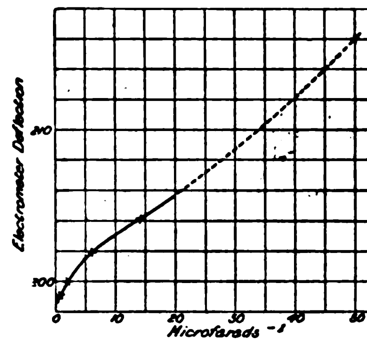

Fig. 5.

The maximum angle of deflection of the needle from its normal position was 7·8°, and tests were made from time to time, especially with the large potentials on the needle, to see if the instrument was in proper adjustment, by placing both pairs of quadrants in connection with the case, and noting the agreement between its then

* Watts deduced by Cosine Law.

of section (*a*) the wattmeter may be said to verify within the limits of accuracy attainable by the method of test. The wave form of the unloaded alternator is given in fig. 3 and marked C; this is the wave form of potential applied to the needle in all experiments in sections (*a*) and (*b*). A sine curve having the same maximum ordinate is superposed for the purpose of comparison. The current curve has different wave form according to the load on the alternator. For small currents it approximates to C in fig. 3. The curve, A, fig. 3, is the wave form for current 74 amperes, which is the maximum we have employed.

The experiments in section (*b*), Table II., are intended to demonstrate the reliability of the instrument when the potential of the needle, C, is varied through wide limits. One would expect from the

zero and the zero when quadrants and needle were put to the case, that is when the instrument was totally discharged. To test the effect of dismounting the instrument the needle was taken off the suspension and the instrument moved to another room and used for another purpose, on December 10th, 1897. On continuing the experiments it was set up by the level only, and found to be in proper adjustment. The results of experiment before and after this removal are given in Table II.

Seeing from fig. 3 how great was the deviation from the sine law, it would have been necessary to analyse each curve by Fourier's theorem, if the subject was to have been treated mathematically the phase difference being given. The current curve was continually changing its form with different loads, and this would have necessitated observing the curve in each case, so that nothing was to be gained by this method of treatment. The potential curve, c, fig. 3, has, however, been analysed,* and can be expressed by the equation—

$$c = B_1 \sin \frac{2 \pi t}{T} + B_3 \sin \frac{6 \pi t}{T} + \ldots .$$

The first five coefficients are as follows:

B_1	B_3	B_5	B_7	B_9
540 1	1·9	31 5	—6 5	1·3

We see that B_5 is important, being about 6 per cent. of B_1; so that from the analysis the cosine law could not be expected to hold. In section (*a*), Table II., the cosine law is applied in two instances for the purpose of illustration. It gives 18·54 as against 17·0 for the watts, per division of scale, for 60°; and 17 2 as against 17 for 36°. For small angles the error does not appear to be so great.

The conclusions arrived at from these experiments are that the Kelvin quadrant electrometer can be used with accuracy as a wattmeter in the case of alternate currents having any phase relation, and that, as pointed out by Dr. J. Hopkinson,† it is necessary to see that within the range of potentials applied, Maxwell's formula is verified. This is, perhaps, best done by applying steady potential differences to the needle and quadrants, and measuring these by Poggendorff's method, employing Clark's standard cell as the unit of comparison. It could also be tested by applying known alternating potentials to the needle and quadrants, the curves being in phase. If it is required to use alternating potentials of high value, such, for instance, as 2,000 volts or more, a suitable transformer could be employed to reduce the potential on the needle. Such unloaded transformer could have the primary and secondary electromotive forces in phase, and of the same wave form,‡ so that no error would be thereby introduced.

The Revolving Contact Maker.

The revolving contact maker, M, fig. 2, exhibits a peculiarity worth noting. It is in itself the seat of an electromotive force, as is demonstrated by placing it across the electrometer, Q_2, and running the machines without excitation. A deflection of 68 scale divisions, corresponding to 0·45 volt, is given if the electrometer has no capacity across its terminals, that is, if G is zero. A copper brush gives the same effect as a steel one. As soon as G is given a substantial value as compared with the electrometer itself, this deflection disappears.

When actually observing potentials in the usual way, let the value of G be varied. For a given position of the contact maker the deflection varied, as shown in fig. 5, in which the ordinates are observed deflections, and the abscissæ the reciprocals of the capacity of G in microfarads. We see that when G has 1 microfarad capacity, the deflection is practically what it would be if G were ∞, and with 1 microfarad the results verify with the true value. Such inductive effect is certainly rendered negligible by sufficient capacity, and it is therefore wise to examine this effect when working with a given contact maker, since each one may have its own peculiarities.

The manganin strip, r_3, r_4, fig. 2, is in lengths of 5 feet, brased together. This material has altered its resistance, as shown in Table III.

TABLE III.

Date.	Resistance at atmospheric temperature in ohms.
November 1st, 1897	0 4625
„ 3rd „	0 4590
„ 13th „	0·4592
„ 20th „	0·4589
„ „ „	r_3 = 0·2269
„ „ „	r_4 = 0 2270
January 4th, 1898	r_3 = 0 2275
„ „ „	r_4 = 0·2277

The strip was mounted on November 1st, 1897, and submitted to currents varying from 100 amperes downwards. On November 20th, 1897, it was adjusted for r_3, r_4. The results show that there is an initial diminution of resistance, and that then the resistance remains practically constant. This is worth noting, as this material is largely used at the present time on account of its low temperature coefficient. The manganin strip is unvarnished and exposed to the atmosphere of the engine room. The conditions are therefore not the best to secure constancy of resistance, but in all probability the initial diminution is due to the brazing.

Messrs. C. J. Evans and H. H. Hodd have given me valuable assistance, not only in the experimental part of this paper, but also in the working out of the results. Messrs. Simpson, Greenbank, and Davey, the present Student Demonstrators in the Siemens Laboratory, have also helped me. I wish to acknowledge this, and to tender my thanks to these gentlemen.

THE INSTITUTION OF CIVIL ENGINEERS.

At the ordinary meeting on Tuesday, February 22nd, Sir John Wolfe Barry, K.C.B., F.R.S., the president, in the chair, two papers, "The Theory, Design, and Working of Alternate Current Motors," by Mr. Llewelyn B. Atkinson, Assoc.M.Inst.C.E., and "Dublin Electric Tramway," by Mr. H. Parshall, M.Inst.C.E.

The first paper was principally devoted to consideration of asynchronous motors, which, although the subject had on two previous occasions been referred to in the *Proceedings of the Institution* (in 1883 and 1889), had not hitherto been discussed. The principles of alternating currents, so far as necessary for their use in alternate current motor design, were first dealt with, and the method of graphically making the necessary calculations was illustrated. After showing the principles on which the continuous current motor was based, and that it consisted of two parts, a field magnet and an armature, the author pointed out that a similar construction (a magnetic field being made of laminated iron) enabled motive power to be derived from alternating currents, provided that means were taken to ensure the phase of the magnetic field, and of the current in the armature being the same. This gave rise to the first class in the classification adopted by the author, that was to say, motors in which the energy was conveyed to armature through brushes, and which were therefore called "conductive motors," which might be series wound, shut wound, or separately excited; in the latter case, the phase of the E.M.F. producing the exciting current differed by a quarter period from that producing the armature current, thus forming an example of the application of multiphase currents to alternate current motors.

The transformation of energy from one circuit to another by electro-magnetic induction, instead of by conduction, was next considered, and by diagrams and curves the working of transformers, both with magnetic leakage and without magnetic leakage between the primary and secondary windings, was illustrated. This gave rise to a class of motors in which the energy was supplied to the armature not through the brushes, but through the air gap; these motors in the simplest form having, however, a commutator for short circuiting the coils so as to produce a proper distribution of current in the armature. The author classed these motors as "inductive motors with brushes, having one inductive electric axis and one magnetic axis."

A modification of this class furnished a third class, "inductive motors with brushes," in which there were "two reciprocal inductive electric and magnetic axes."

The brushes might then be dispensed with, giving rise to a class of "inductive motors without brushes, having short circuited coils and two reciprocal inductive electric and magnetic axes," the modern induction motor. The author proceeded to examine in detail the theory of such motors, and showed how, by means of a diagram, its properties might be determined. It was then pointed out how, in such a motor when running, the supply on one phase might be eliminated, and the motor would remain self-exciting, furnishing itself a magnetising current in phase with the supply current, thus forming the modern monophase induction motor.

The supply might be on any number of phases, to the same number of magnetic systems, provided that a proper relation existed between the two.

The use of asynchronous motors as generators was next touched upon, and the author showed that the various motors explained might be used as motor generators, in which case not only the pressure, but the phase of the current, might be changed. All these machines might be used as generators, and the various combinations of motors and generators of this class were illustrated.

In a second part of the paper, the author dealt with the design of alternate current motors, and showed the necessary conditions to produce the proper distribution of currents in the armature and of the magnetic field, and further, gave a formula for determining the proper loading of the armatures, and from this showed how all the other dimensions of a machine for any given power might be derived. The wave form and frequency, as affecting alternate current motors, were discussed, and examples were given showing to what extent the necessary conditions were realised in practice.

In the third part the author dealt with the practical construction and working of asynchronous motors, and taking each class described, illustrated them by examples so far as they existed, and tests where these were available. This part was illustrated by curves and data relating to a large number of different classes of motors. Curves were also given showing the relative weight of continuous current motors, single-phase motors, two-phase motors, and three-phase motors.

The second paper embodied an account of the Dublin Southern Tramways, which was to some extent peculiar, in that the installation, as originally designed, would not conform with the Board of Trade regulations in the matter of the fall of potential in the earth return. The machinery had been ordered and the work proceeded with before the author had been called in to advise in the matter. The problem became, therefore, to utilise as much of the machinery ordered as possible, and to instal such other machinery as would be necessary to distribute the electricity under the Board of Trade regulations. The high-tension alternate-current method of transmission was considered most suitable. It was necessary to make use of the sites owned by the Tramway Company, and to execute the work as cheaply as was consistent with safe operation. The three-phase machines and switchboards were specially designed for the installation, which was the first one of its kind established in the British Isles. The installation had been in operation for nearly two years, and had been found entirely satisfactory. The operation of the sub-stations had been found to be very simple, so simple, in fact, that only a boy was employed in each station to work the machinery. Owing to the low frequency the motors were very easily synchronised, and even though they were thrown in considerably out of phase, they quickly fell into step. Since the opening of the road the load had been greatly increased by a considerable number of additional cars and trailer-cars, yet the machines had never given trouble, nor had the synchronous motors fallen out of step, even in the case of the most severe loads. The requirements of the Board of Trade had been satisfactorily met, and owing to the number of points of distribution it was possible to work some 60 cars on the line instead of 20, as originally designed to comply with the Board of Trade regulations. As originally designed, the fall of potential in the earth return would have been some 18 volts to 20 volts, whereas in the present installation it was found to be 3½ volts.

The installation was, perhaps, most interesting from a commercial rather than from an engineering standpoint, in that it illustrated how traffic might be developed by an improved service. Formerly the traffic was worked by three disjointed horse lines, none of which were profitable. They were finally sold for about £14,000, whereas the value of the present property was estimated at £300,000, and the revenues were consistent with this figure.

At the time the installation was designed the total number of cars contemplated was 20; since that time it had been found profitable to work as many as 50 cars on the line, even though the line had been subjected to the disadvantage of not having a through connection to the centre of Dublin. Owing, therefore, to the largely increased load, the capacity of the power house at Ballsbridge had been greatly added to by a large direct-connected unit which was more suited for heavy traction loans. Likewise the sub-station at Blackrock had been re-designed, and in the place of the 60-kilowatt motor-generator sets originally installed there were two 200-kilowatt rotary converters, with the necessary static transformers, and an improved switchboard for manipulating it.

The principal point of importance was the ease and reliability with which such a system was shown to be operated. The efficiency of the system was shown by the working cost to be satisfactory, although, as might be gathered from the paper, the efficiency of the machines in the sub-stations was not so high as would be the case with larger machines and larger rotary converters. For a small tramway installation, however, the sureness of operation and the minimum of labour were of vastly greater importance than any small gain in efficiency.

SOME AMERICAN METHODS.

II.

The Gray planer shops in Cincinnati are another sample of that rapidly growing practice of a firm confining itself to the manufacture of one article. In England we have been too diffuse, not merely in mechanics but in all subjects, too diffuse that is for modern success. The diffuseness of English practice is never more markedly shown than when some successful Westminster engineer is called in to advise perhaps on sewage disposal, because he has made a name on a canal or a bridge. In matters of everyday life we don't call in our solicitor to cure us of a fever because he has won a case for us at law; but we do just such things when it comes to questions of engineering, and the sight is familiar of expenditures of thousands of pounds under the advice of a noted engineer when a few hundreds would have secured a better result. This same habit is carried out in mechanical engineering. A tool-maker makes planers, lathes, drills, and the whole range of machine tools. We hear that Smith's lathes are the best, and Jones's planers are the best, but Smith still makes planers and Jones gaily carries on his trade in lathes. A friendly understanding, honourably carried out between them, would result in each man making one only of these machines, leaving the other to his rival.

In America they practice this concentration very largely, and in the Gray shops they stick to planers. This company scrape neither beds nor tables to fit, except just to remove loose particles of iron.

Accurate tools and "know how" eliminate scraping. One sample of "know how" is the use of two tools to plane the V's of the bed. The tools balance each other as to cutting pressure, and do accurate work by relieving the bed of so much stress, leaving the finishing tool with very light work to perform.

In the Bickford drill and tool shops the same idea prevails, and a total of 23,000 square feet of surface of floor is devoted solely to drilling machines. It is obvious that the process of selection will tend to secure for each of the shops just named, the best available talent at planers and drill presses respectively. Unite the two shops, and one of the two men would be the stronger, and would impress his inferior ability upon the better weaker man, and either the planer or the drill would be inferior for lack of the specialisation. In the Fay and Egan wood-working machine shops, they were estimating for machinery to turn out 300 freight cars daily in a Russian works, contemplated to be, therefore, six times the output capacity of the largest American car works, and no doubt Russia will be a large field for machinery, which our own works ought to look into now they have the prospect of working on better lines.

In the shops of the Laidlaw-Dunn Gordon Company everything is carried out with a view to economy of operation. Thus, if a man wants a tool, he presses a button and rings up a number in the tool room, a boy answers the call and takes the man what he requires; and no doubt a few boys must save the time of many men going to and fro for tools.

The new shop of this company is 665 feet long and 113 feet wide, with overhead traveller and side lights above the traveller. All the heavy tools are placed on one side and light tools opposite, the castings passing across the shop and so reducing handling. The large traveller is 15 tons capacity, electrically worked, and there are numerous air hoists suspended from jib cranes. In the Lodge and Shipley shops, the speed pulleys of lathes, which are the sole product of the company, are crowned at one operation by a full width tool. Some of these tools are 4 inches wide.

A custom in the tool shops of this locality is that of making all small parts of machinery from samples. After a new machine has been set up and tested, it is taken apart and its pieces used as samples, being placed in the sample room and all subsequent parts are made to these samples. The last named company carry the idea into their purchase department, which contains samples of all they require in the way of supplies, as sand and emery papers, drills, screws, wrenches, in fact, one of every standard article they purchase, numbered and catalogued.

In the shops of the American Laundry Machine Company there is a board about 30 inches × 38 inches, carrying two pins for every size of machine of every style they make. On these pins are hung different coloured poker chips. These show the number of machines in stock. Thus, when an order for 12 machines is sent into the shop there are, say, 12 red chips hung on the upper of the two pins proper to that machine. As each machine is completed one chip is removed from the upper to the lower pin. Blue chips represent orders from outside, and a blue chip is removed as each machine is shipped. The system is a great aid in showing progress of orders, &c. Other boards fulfilling similar ends are used in these shops, one, for example, with the days of the month, carries hooks and clips containing the orders to be filled on the different days. These boards are always at hand showing when work is to be shipped.

There is also a telephone system whereby a call is made in every department for the man wanted at head quarters by means of a push button and bell. On hearing his call the foreman wanted goes to the telephone and replies. The bell in the Superintendent's office rings in unison with the rest. The telephone itself is simply the old speaking tube system. The calling only is electrical, as the old tubes required so much lung power to sound them.

In an engine shop was found an old lathe, dating back authentically to 1832, and known to be older by several years. It is used for facing columns, and is holding its own to-day, though its shears are bolted to stout wooden beams, and the carriage is operated by a crowbar. If this tool were seen by a travelling American in an English shop, it would be published and illustrated as a standard sample of the ways of the Britisher. We do not doubt that though old it may be quite equal to anything for the work it is doing, but as it calls forth the daily eulogiums of the manager, we think it might pay to put in a less interesting specimen, if only to save the time of the manager. However, it is satisfactory to know that even in America age does not necessarily condemn.

JAPANESE COPYING.

Some good articles on "Engineering in Japan" have been recently appearing in the *Engineer*. Referring to the charge that the Japanese copy European and American designs, as though such were a rascally thing to do, our contemporary hints that did they not do so the Japanese would be a trifle idiotic. All round originality in the design of a machine can scarcely be possible to-day. Should they elect to build a locomotive, they could not get far away from European or American types, and even so original a people as the Americans, have only been able to elaborate the old English locomotive on lines from which the English themselves departed more widely than the Americans, who, however, every day are more nearly approaching European forms as their country approximates more nearly to Europe in its settled areas. We have often thought that much valuable time is wasted in the endeavour to make new departures without sufficient reason. Did the Japanese contrive their products widely different from the existing examples before them—the outcome of a century of trial, error and endeavour, it would be looked on as a proof of overweening conceit. Sudden and wide departures from the plan and system of a steam engine, a gas engine, or a spinning frame, are not possible. All existing types of spinning frames to-day, are obviously only developed from the small machines of Crompton and Arkwright, and it is only during the past few months that the first departure has been made in the loom for several thousand years, and the departure now made is not a matter of a difference in the machine, but the discovery of a novel principle in weaving. Before the Japanese or anyone else can make departures in design, they must invent new principles of action. To-day we are as Watt left us with the steam engine, and use the same designs where we follow the piston principle. But if we abandon the principle, we easily get a new design in the steam turbine. The gas and oil engine are almost identical in principle with the steam engine, and they follow its mechanical lines very closely.

In this charge of copying it is therefore very unfair to charge bad faith upon copyers. Originality is well in the proper place, and may be evidence of good judgment and correct taste, but it is as often a sign of weakness. A weak man will re-design a machine because he has not the courage to confess that some other man's design is better than he can do himself. If all engineers aimed at being original in place of being good managers, there would be an immense amount of waste. It is in too much striving after originality at others' expense that engineers so often waste money. It should be our aim to see that English models come into Japanese hands so as to lead them in the direction of English systems and ideas. We surely cannot find fault with a people only just at the beginning of their engineering life for utilising Western experience of a hundred years.

NEW PATENTS AND ABSTRACTS OF PUBLISHED SPECIFICATIONS.

NEW PATENTS.—1898.

[*Compiled expressly for this journal by* W. P. Thompson & Co., *Electrical Patent Agents*, 322, *High Holborn, London, W.C., to whom all inquiries should be addressed.*]

4,471. "Wareham's electric clock or time recorder." E. Wareham. Dated February 23rd.

4,508. "Apparatus for metering electrical current." W. A. Price. Dated February 23rd.

4,516. "Improvements in holders for the brushes or collectors of dynamo-electric generators and motors, and other revolving electric machines." J. Matthews and G. B. Cruickshank. Dated February 23rd.

4,549. "Apparatus for electrically controlling the hoisting mechanism of elevators or any other type of machinery." H. H. Leigh. (F. J. Sprague, United States.) Dated February 23rd.

4,550. "Improvements in telephone signal systems." E. Edwards. (W. Stillwell and A. Barneck, United States.) Dated February 23rd.

4,588. "An improved method of, and means for, holding the bases of electrical fittings within boxes, or upon other surfaces." F. Bathurst. Dated February 24th.

4,621. "Improvements in electric arc lamps." A. F. Spooner. (P. Vassia, France.) Dated February 24th.

4,635. "Improvements in apparatus for travelling through pipes or conduits, more especially intended for use in threading through electric conductors." H. Edmunds and A. H. Howard. Dated February 24th.

4,646. "Improvements in apparatus for magnetic testing." J. A. Ewing. Dated February 25th.

4,678. "Improvements in insulation of wire for electrical purposes." C. E. Hearson. Dated February 25th.

4,683. "Improvements in electric accumulator grids." A. Schanschieff. Dated February 25th.

4,742. "Improvements in devices for lighting lamps by electricity." C. M. White. (H. M. Brigham and S. M. Meyer, United States.) Dated February 25th. (*Complete*)

4,746. "Method of, and means for, measuring the work performed in a rotary phase current system." Siemens Bros. & Co., Limited. (Siemens & Halske Aktien-Gesellschaft, Germany.) Dated February 25th.

4,747. "Improved means for counterbalancing the frictional resistance in alternating current motor-meters." Siemens Bros. and Co., Limited. (Siemens & Halske Aktien-Gesellschaft, Germany.) Dated February 25th.

4,761. "Improvements in electric controlling and regulating apparatus." W. Emmott. Dated February 26th.

4,764. "Improved process and apparatus for tanning by the aid of electricity." N. P. Andersen, J. Westergaard and H. Zerener. Dated February 26th.

4,791. "Improvements in connection with the mechanism of electrically illuminated devices." W. H. Clegg, J. S. Richardson and S. Jevons. Dated February 26th.

4,812. "Improvements in or connected with alternating current electric motors." A. Heyland. Dated February 26th.

4,819. "A method of electrically heating materials in closed chambers and apparatus for that purpose." Electric Reduction Company, Ltd. (W. T. Gibbs, Canada.) Dated February 26th.

4,820. "Improvements in electric arc lamps." Siemens Bros. and Co., Ltd., and F. Booker. Dated February 26th. (*Complete.*)

4,825. "Improvements in or relating to electric accumulators." C. Junge. (R. Knoschke, Germany.) Dated February 26th. (*Complete.*)

4,828. "Improvements in electro-magnetic couplings for shafts, pulleys, and the like." H. H. Lake. (W. Dierman & Co., Belgium.) Dated February 26th.

ABSTRACTS OF PUBLISHED SPECIFICATIONS.

Copies of any of these Specifications may be obtained of Messrs. W. P. Thompson & Co., 322, High Holborn, W.C., *price, post free,* 9d. (*in stamps*).]

1897.

13,971. "Improvements in and relating to controllers for electric motor circuits." The British Thomson-Houston Company, Limited. (E. D. Priest.) Dated June 8th, 1897. Relates to various improvements in controllers operated by fluid under pressure, and consists of employing a number of pistons to vary the resistance of the circuit by cutting out the resistance or change the motor connections from series to parallel or *vice versâ*. Arcing is prevented by blow-out magnets, and the coils are protected against injury by a piece of refractory material, a similar protection being afforded to the pole-pieces. The valve mechanism for operating the parts is divided into two parts, one valve for the resistance contacts, and the other for changing the combinations of the motors; both valves are operated by a single handle by means of gear wheels. 31 claims.

17,144. "Improvements in flexibly insulated conductors." J. H. Kelman. Dated July 20th, 1897. Relates to a method of insulating conductors, and consists in coating the conductors with a thin coating of boiled linseed oil, and hardening by oxidation. Various methods are devised whereby the wire may be coated and hardened. 11 claims.

18,095. "Improvements in method and means for operating and alternating current motors." The British Thomson-Houston Company, Limited. (C. P. Steinmetz.) Dated August 3rd, 1897. Relates to a method of enabling an alternating current motor to be run at full efficiency and at different speeds, or at full efficiency when fed with currents of a periodicity much higher than would be permissible were the motors connected directly to the line in the usual manner, and also to obtain the same good results in regulating the power and speed of a number of alternating current motors as are obtained by the use of the "series parallel" method of control used with continuous current motors. 21 claims.

13,977. "Improvements in three-phase alternating current induction meters." The British Thomson-Houston Company, Limited. (C. P. Steinmetz.) Dated June 8th, 1897. Relates to a three-phase induction watt meter, and consists of a closed-circuit armature and magnetising coils, comprising current coils in two of the main lines, and two potential coils in circuit with electromotive forces which are in quadrature with the electromotive forces between the third main and the two mains carrying current coils. 6 claims.

6,243. "Improvements in and relating to the protection and support of underground electric conductors, principally applicable for electric railways and tramways." H. S. Cowx. Dated March 10th, 1897. Relates to conduits composed of lengths of a trough-like section placed end to end to form a channel, and if necessarily, supported at the centre of its length. At the ends where each length joins the next length a chair is provided supported on a sleeper. The chair is of similar section to the trough and fits closely. Between the ends of lengths of the conduit and the chair which supports it is placed a waterproof slip. Upon each side of the chair is placed a metal plate secured by set screws and firmly holds the waterproof slip and thus protects the ends of the circuits. A series of plates form a partial covering for the channel and is filled in with the ordinary road material, spaces left at the sides allow the collector to pass in. 6 claims.

1,887. "Improvements in or connected with incandescent electric lamps." The British Incandescent Electric Lamp Company, Limited, and H. E. Maul. Dated January 23rd, 1897. Relates to a method of connecting the cap to the neck of the electric bulb of an incandescent lamp without the use of cement. A groove is formed in the neck of the bulb by blowing, and the cap is secured to the bulb by a wire secured to the cap and entering the groove in the neck of the bulb which the said wire should fit sufficiently truly to hold the bulb firmly in position. 2 claims.

6,695. "Improvements relating to electric tramways and railways on the sectional conductor system." H. H. Lake. (R. Arno and A. Caramagna.) Dated March 13th, 1897. Relates to electric tramways and railways on the sectional conductor system, and consists of fixing to an armature an arm of a conducting and dia-magnetic part and of an iron portion. On the armature being attracted the iron portion of the arm dips into the mercury electrically connected with the branch of the cable, and contained in the cup floats a small spherical carbon block. The lower cavity is also filled with mercury. Other modifications are shown. 4 claims.

THE

ELECTRICAL REVIEW.

VOL. XLII. MARCH 18, 1898. No. 1,060.

CONTENTS:

THE ELECTRICAL REVIEW.

Published every FRIDAY, Price 4d.

The Oldest Weekly Electrical Paper. Established 1872.

TO BE OBTAINED BY ORDER FROM ANY NEWSAGENT IN TOWN OR COUNTRY.

OFFICE:—4 LUDGATE HILL, LONDON.

Telegraphic Address: "AGEKKAY, LONDON." Code A B C.

Telephone No. 963 Holborn.

All Letters should be addressed to the Proprietors, H. Alabaster, Gatehouse & Co.

ADVERTISEMENT RATES ON APPLICATION.

The "Electrical Review" is the recognised medium of the Electrical Trades.

SUBSCRIPTION RATES.—In *Great Britain*, Post Free per Year, 19s. 6d. To all other countries, per Year, £1 4s.

BINDING.—Subscribers' numbers bound, including case, for 4s. each volume.

CASES.—Cloth Cases for Binding can be had, price 2s. 6d. each.

READING CASES, to hold from One to Twenty-six Numbers until the Volume is complete for Binding, can now be had from the Publishers, Price 6s. or Free by Post (in Great Britain), 6s. 6d.

FOREIGN AGENTS.—*New York*: D. VAN NOSTRAND, 23, Murray Street. *Paris*: VEUVE J. BOYVEAU, 22, Rue de la Banque. *Berlin*: ASHER & Co., 5, Unter den Linden.

Cheques and Postal Orders (on Chief Office, London) to be made payable to Mr. H. ALABASTER, 4 Ludgate Hill E.C.

BRADFORD CORPORATION AND THE ELECTRIC TRAMWAYS.

THE *Railway World* exposes what to us seems a very questionable procedure on the part of the Bradford Corporation in respect of the electric tramways.

The particular and most glaring offence seems to be that, in calling for tenders, the Corporation has specified certain particular articles only purchaseable from particular firms; for instance, rail bonds of a special type, trucks made by a designated manufacturer, car motors of the General Electric Company's make.

Our contemporary has no fault or otherwise to find with the special articles desired and specified, but says, why ask for tenders when certain makers must be dealt with? For our own part, we do not think so much of this as does our contemporary. An individual who would build a tramway for himself would probably select what he wanted, and buy it as he pleased; but corporate bodies are supposed to have less liberty, and often this obligation to call tenders publicly results in cutting prices and bad work. But the Bradford Corporation has not stopped at this point. On the obligatory specification put forward, there were four tenders, ranging from £15,067 to £16,460—a remarkable closeness, the highest three being within a £200 range. Probably to show to the Corporation the error of their ways, one of the tendering firms—the Westinghouse Company—put in an alternative tender for £14,814, on the basis for their own apparatus in place of that specified. None of the firms had permission to put in alternative tenders, or doubtless would have been glad to do so. The one firm that did had its tender accepted. Now, this was manifestly unfair to the rest. The Corporation asked tenders for a certain thing, yet accepted something else from a firm which went outside the specification. Obviously, when the Corporation threw their preconceived notions to the winds and decided to tear up their stringent specification, it would only have been an act of common honesty to say so, and to call for open tenders. If Dick, Kerr & Co. could underbid Westinghouse by £1,200 on the close tender, the inference is they would have sent in a tender on their own lines for probably not over £14,000, and beaten the Westinghouse Company. The glories of self-government are apt to be dimmed somewhat when one has had much experience of municipal work. When there is anything more than usually technical in hand, committees seem to act without their engineer or surveyor, and, as a rule, if contractors appear before them, an *ex parte* statement may win the order.

We have not seen the specifications which were got up by the surveyor, Mr. Cox, and by the electric light engineer, Mr. Gibbings, neither of whom, in our contemporary's opinion, however good in their own special line, can be considered likely to be *au courant* in traction work. The complaint is made that the specification is full of unnecessary details, while the two Corporation engineers are to be sole adjudicators of sufficiency and quality in respect of work in which their very position in other and different lines implies they are not specialists. The specification gives conditions and tests, and, as stated above, in certain cases makes certain goods obligatory. In specifying the trucks by a given maker, the details of the trucks are elaborated. Why this unnecessary elaboration? This supererogation?

It seems to have occurred to the Bradford Corporation when they discussed the tenders, that the method of procedure which had been followed by their engineers was likely to prove costly, and that there was a chance of saving nearly £2,000 by taking a more liberal stand, and no doubt they were, so far, perfectly in the right. But they were evidently so overwhelmed with the idea of saving the amount, that they stood not upon the order of their saving, but saved at once by accepting the Westinghouse tender forthwith, never seeming to grasp the idea that other firms if free to enter in by a side door might have done still better.

It is quite possible that no member of the meeting had any idea of the basis on which the four first tenders were made. Probably they did not know just what the Westinghouse second tender was alternative to. We have no information as to what the engineers did in the matter. Their duty was to tell the Corporation the facts, and that they could not honestly accept the alternative tender. Of all this we are uninformed. We do know, however, that where there are obstinate men on a committee, the position of the surveyor or engineer is often not a happy one. Half the members of a vestry have a particular crank of their own, and are a perpetual thorn in the side of the poor engineer. If every shareholder of a railway were allowed to inflict himself upon the engineers in the way that members of corporate bodies inflict themselves on their surveyors and engineers, the working of a railway would become impossible.

The Bradford affair differs from what was known as the West Ham scandal of a year ago. At West Ham the tenders accepted amounted to about 50 per cent. in excess of the lowest tenders, had these been summed up. The explanation offered was that, in the engineer's opinion, it would be to the advantage of the public that the accepted tenders should be taken. There was a complaint from an unsuccessful firm, who were lower than the tenders accepted. They argued that as they were a company of repute, and the work had to be done to the satisfaction of the West Ham engineer, why, therefore, should thirty shillings in the pound be paid for work ostensibly in the power of the engineer to insist upon being to his liking.

The question of accepting the lowest tender is a very vexed one. Work is put out to public competition with a view to cheapness, and apparently the lowest tender of any reputable firm should be the one accepted. Even when a tender is put in at less than will pay for a good job, this is no reason to doubt the good job being secured. There may be half a dozen good reasons for tendering below cost—reasons of finance, of advertisement, and of keeping the works going. It is sometimes cheaper to work for nothing than it is to succumb to temporary slackness by discharging old hands and spoiling one's character for being a steady shop. Shops which discharge their men freely and frequently never secure more good men than they have permanent jobs for. Public tendering generally implies, then, the acceptance of the lowest tender, and this they failed to do at West Ham. At Bradford, on the other hand, they did accept the lowest tender, but it was a tender for something with which they had particularly requested not to be supplied, and most of the firms tendering had acquiesced, and tendered for what was required. One firm only tendered for entirely different goods of its own make, and, therefore, presumably cheaper, and got the order. Hence the trouble. There was a doubt at West Ham, but it was not shown that there had been any wrong doing. The Bradford affair, on the face of it, is distinctly discreditable, and though an explanation is generally thought should be forthcoming, we fail ourselves to see how the matter is to be explained, other than by boldly admitting sheer thoughtlessness, or a spirit of don't care.

Moses G. Farmer.

It is very difficult for the mere men of the crowd to contemplate with other than wonder, or perhaps curiosity, the mental attitude of a man like Moses G. Farmer, who pursued science without a thought of the solid personal benefits to be derived from it. To-day most of us, as soon as we have discovered some new fact or discerned some new bearing of an already ascertained fact, hasten to publish it, in order to obtain for ourselves priority. Indeed, in some countries, notably in France, there is an elaborate system of sealing papers, whereby a man may state in general terms something into which, perhaps, he has obtained some insight, and then when someone else comes forward at a later date, he can produce from the archives of the Academy of Paris his hidden statement, which guarantees him that much coveted priority. Vanity is doubtless at the root of this curious practice. This quality, for it is a quality, and a good one if it is properly balanced, is the last which we could possibly ascribe to Moses G. Farmer. In him the world had a clever, industrious worker, who observed, deduced, and noted down facts, which, had they been published at the time, would have covered him with honour and renown. We can quite sympathise with this modesty, but to-day can see the pity of it, for had those notebooks been given to the world, applied electricity would, without doubt, have come more rapidly into prominence in the industries of mankind than it has done. It may be said that the new science has come on quite fast enough, but useful progress in the application and acquirement of knowledge cannot proceed too rapidly. To-day our American contemporaries are recognising that Moses G. Farmer was a great inventor. In an address before the American Institute of Electrical Engineers, Dr. George F. Barker has pronounced a well merited eulogium on the man and his work. It would be a good thing for the rising generation of electrical engineers if a biography of Farmer could be placed in their hands. It would prove not only interesting and encouraging, but inspiring. In Farmer's work there was no cheap clap-trap, no striving after effects which would dazzle the multitude, no dashing about in order haply to light upon the fact of which he was in search, no rule-of-thumbism. He proceeded slowly and steadily, measuring his paces and calculating his distances, until he was able to gain the end he had in view. Nothing is so characteristic of this than a little incident which took place in 1860, when, on the celebrations in connection with that American Saints' day, July 4th, an exhibition of the electric light was arranged to take place on the Boston State House. Prof. William B. Rogers had charge of the exhibition, and a very large battery was placed in the dome, and wires were led up, and this light was shown at the same time with the fireworks on Boston Common. There was somebody else up there beside Prof. Rogers and his assistants, and that man was Mr. Farmer. They wanted to make a display; they wanted to show an electric light larger than any that had been seen up to that time. Mr. Farmer had no such idea. He wanted to do what had not been done in the world before, and what has not been done, possibly with one exception, since. He wanted to determine how much power, how much horse-power it required to produce that light, and out of the data which he obtained in those experiments in the dome of the Boston State House on that night of July 4th, 1860, was the mechanical equivalent of light, and he gave us the fact that to support the light, not the heat, but the light of one candle required the expenditure of 13·1 foot-pounds per minute. Some time after that Prof. Thomson, of Copenhagen, undertook from similar data to get a result, and the results were very closely accordant. It is sincerely to be hoped that Mr. Farmer's note books will be edited and published. Their contents are believed by those who have inspected them to consist of matter which was new science at that time. He was a great inventor, and deserves that certain discoveries which figure in those note books should be credited to him. The work of Farmer has passed unconsciously into the work of others, but had his individualism been more energetic, he would have been recognised during his life as one of the greatest leaders in the application of electricity.

SOME NOTES ON SINGLE-PHASE MOTORS.

By A. C. EBORALL.

(*Continued from page* 277.)

At first sight it might appear that it would be more economical and cheaper to put the starting resistance in series with the *stator* for the purpose of reducing the starting current. This is, however, not possible, as the output of an induction motor is practically proportional to the square of the supply pressure, and hence the reduction of this at starting would, in the case of single-phasers, prevent the motor starting at all. Hence this is never done in practice.

It may be remarked here that the fact of the output of an induction motor being very approximately proportional to the square of the impressed pressure, makes it essential that the regulation of any motor circuit should be fairly good, because should the tension on the line suddenly decrease from any cause, such as might be produced by starting up a large motor too quickly, or without its resistance, any heavily loaded motors on the circuits at the time might pull up; for a motor that would carry considerable overload at its normal tension, would barely take its full load with a reduction of 25 per cent. in the line pressure. As, however, single-phasers are only used in conjunction with lighting systems, it follows that the amount of overload such a motor will take will practically depend on the quality of the design.

The above is the only way in which the pressure on the stator affects the speed regulation of an induction motor—whatever the number of phases.

The effect of frequency on the running performance of a single-phase induction motor is not very greatly felt between 30 and 60 ~ in a given design, although it may make considerable difference to its starting powers. Theoretically it should make no difference at all, and would not do so except for the fact of the motor poles increasing directly with the frequency for a given speed. That is, in large motors, the poles become very numerous as the frequency is increased, because the speed of such motors must not be too high. The effect of increasing the poles in any given type of machine is to increase the magnetising current and also the leakage. It is this last factor that counts the most, and so in high frequency motors the power factor is not so good, and the starting rendered more difficult than in those working at the same speed on a circuit of moderate frequency.

The whole question of the design of induction motors really resolves itself into this question of leakage, which takes into account nearly all the quantities involved, such as dimensions of air-gap, induction density in it and in the stator, depth of winding in stator, and distribution and form of winding in rotor and stator. The induction motor with least leakage will always start best, have highest power factor, least slip, and hence be better all round.

Having now considered the broad principles underlying the construction and running of single-phasers, it may prove of interest to describe the different starting devices actually used by the various makers, and to briefly discuss the results attained.

(*A*) *Messrs. Brown, Boveri & Co.*—This firm was the first in the field with a commercial single-phase motor, and many hundreds have now been sold, in units ranging from $\frac{1}{10}$th to 70—80 H.P. The table given below shows the weights, efficiencies, &c., of stock sizes of their motors, arranged for running on circuits of 30 to 60 ~, and 100 to 500 volts.

TABLE I.

Reference number.	1	2	3	4	5	6	7	8	9	10	11	12	13
Horse-power	0·1	0·3	1·0	2	3·5	6	9	13	20	35	45	65	90
Approximate weight (in pounds)...	40	60	140	240	400	620	1,000	1,400	1,700	3,100	4,000	5,200	6,800
Full load efficiency (per cent.) ...	50	60	65	70	73	76	80	84	88	90	90	90	91
Apparent watts per H.P.	2,260	1,750	1,570	1,420	1,330	1,240	1,150	1,080	1,020	1,000	1,000	1,000	990

The weights given include starting apparatus and rotor resistance when this is used. The larger motors (from about No. 10 upwards) can be arranged for any tension up to 5,000 volts, this being transformed down for the starting winding.

Motors up to No. 5, inclusive, have simple short-circuited bar rotors, and must start on a loose pulley. The starting current is about equal to the full load current. From No. 7 to No. 13, the rotors are all wound with three slip-rings on the shaft for the insertion of a resistance, as before described. If they start on a loose pulley, the starting current is somewhat less than the full load current, but they will all start against some load if enough current is allowed them. No. 6 can either have a plain or wound rotor, depending on the frequency. For higher frequencies than 60 ~ the wound rotors commence at either No. 4 or No. 5.

The different starting arrangements used with these motors are as follows:—

For motors up to and including ½ H.P., the device shown in fig. 11A is used. At starting, the working and starting windings are put in series, the latter being shunted by a non-inductive resistance. The current will, therefore, lag more in the working than in the starting winding, and hence, as

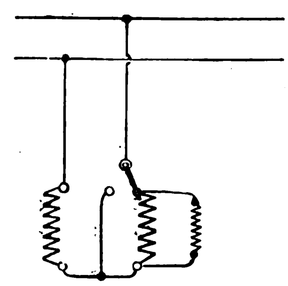

FIG. 11A.

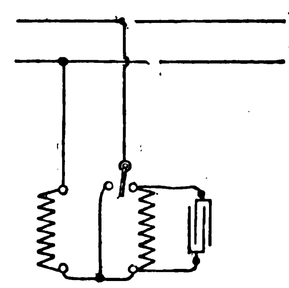

FIG. 11B.

the two windings are displaced 90° from one another, an imitation rotary field will be produced, causing the rotor to very quickly run up to speed, when the starting coils and resistance are cut out, and the working coils put direct on the line.

Fig. 11B shows the arrangements for motors above ½ H.P., and up to 6 H.P., when a starting resistance in the rotor is not used. The arrangements are exactly the same as in the first case, only the resistance shunting the starting coils is replaced by a liquid condenser. The leading current in the starting coils acts in just the same way as in the other case, causing the rotor to very quickly run up. The liquid condensers employed are very simple. They consist of a number of thin iron plates, separated by thin fibre strips, and arranged in an enamelled iron vessel containing soda solution. The manner in which the plates are connected (*i.e.*, in series or parallel), and the density of the soda solution employed, is determined for each individual motor, the solution, &c., being adjusted in the test-room until the best effect is obtained, the whole adjustment occupying but a very few minutes. It is necessary to treat each case separately, as minute differences in the air-gap, and differences in the windings for varying voltages and frequencies, prevent the condenser arrangements being exactly standardised.

These liquid condensers are practically indestructable, and never get out of order if properly made and used. A little water must be added occasionally to make up for evaporation. To give an approximate idea of the size of one of these condensers, it may be stated that the overall dimensions of one for a 4-H.P. motor would be about 9½ inches long by 6¼ inches wide by 8½ inches deep.

Fig. 12A gives the starting arrangements used for all Brown motors where a rotor resistance is employed. The resistance having its maximum value, the line current is switched directly on the working winding, the starting

D

winding, in series with a liquid condenser, being in parallel with it. The artificial rotating field produced causes the rotor to run up. As it runs up the rotor resistance is gradually reduced, the condenser and starting coils being cut out at about two-thirds of the normal speed.

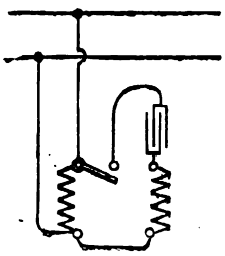

Fig. 12a.

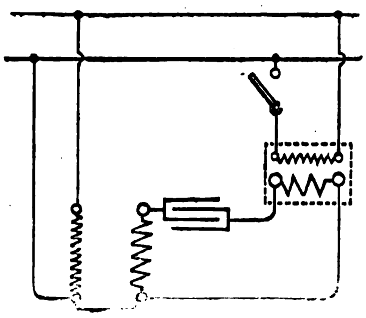

Fig. 12b.

The last arrangement described is somewhat modified in the case of large high-tension motors. Thus fig 12b shows the starting arrangements used with some 70 H.P. Brown motors at Frankfort. They are worked direct from the primary network at 2,800 volts. The working winding is straight on the mains as in the last case, but the starting winding and condenser are connected to the mains through a small transformer, which reduces the pressure to a lower value more suited to the condenser. When at about two-thirds of the normal speed, the transformer, &c., would be switched off.

Fig. 13 gives a view of a Brown starting resistance and condenser. The resistance is a star-connected non-inductive nickeline wire resistance, it being enclosed in a cast-iron box filled with oil. This arrangement allows the use of a high current density in the wires, owing to the excellent cooling afforded by the oil. The contacts, giving five degrees of variation up to the short circuit position, are arranged on the marble cover, and the whole forms a very compact and efficient arrangement. The external appearance of the condenser is well shown in the photograph.

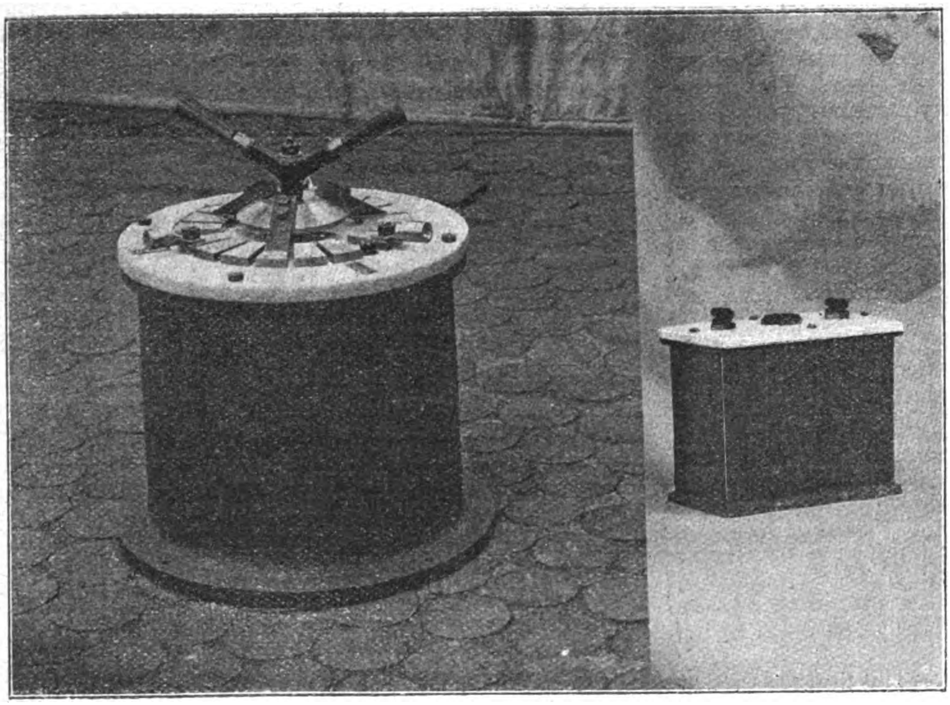

Fig. 13.

(*To be continued.*)

Electric Police Lanterns.—It is stated that the authorities at Scotland Yard are now engaged in subjecting a police electric lamp to practical tests, to ascertain if it will stand the necessary wear and tear of the service.

SERIOUS BREAKDOWNS FROM PRIMING.

Yarmouth was reported last week to have been in a state of darkness, the whole of the electric lights being suddenly extinguished. To make a long story short, we learn that three Willans engines and one of another make were suddenly wrecked by what is generally held to have been a sudden and excessive priming of one or more boilers, but whether caused by overfeeding or otherwise we suppose may never be known. An exceedingly funny report appears in a Norwich paper—evidently of non-technical origin. As usual with such, things seem to have been *hurled* about, and *ponderous* masses of iron so hurled have done a lot of *rebounding*. In fact, the description of hissing steam and roaring water seems to point to a sort of Niagara let loose in—the paper calls it Pandemonium, which seems about seven letters too long. Unless the water be very dirty, boilers which do not prime as a rule, do not suddenly give large volumes of priming, but if the water level has been allowed to get too high, the rush of steam over its surface might set it in motion, and finally gather it up in a vortex and produce the damage recorded. The idea of priming being the cause seems to be borne out by the simultaneous damage of four engines at once. The boilers are, we understand, of the water tube variety, and we believe there were no water separators on the steam pipe. A water separator is a fairly efficient instrument for producing dry steam, *i.e.*, steam free from a serious amount of water in a mass. The steam may remain misty but this will not damage engines. The main steam pipe from boilers to engine ought to bend at an absolutely square bend, the pipe from the boiler being continued a few feet past the branch to the engines, and terminating in a fair sized vessel drained by a good trap.

The engine branch may best be taken off square from the top of the steam main. Another suitable water-trap is to carry the steam pipe into the side of a fairly capacious vessel, the pipe turning down inside and discharging its steam and water towards the bottom of this vessel, which should be of some depth. The outlet should be from the top, and the cross-section of the vessel should be quite four times that of the steam pipe, so that the upflow of steam may be slow. A vessel like this in the length of the steam pipe would deal with sudden masses of priming, but it is obvious that it should be of some considerable depth and size so as to deal with the largest probable bulk of water. Of course, the sudden priming of a few gallons or even quarts might wreck several engines. A thimble full in a cylinder beyond what will fill the clearance space will wreck an engine. Even where relief valves are fitted these are never more than sufficient to discharge just the small amount of ordinary wetness which may accumulate in the cylinder, and is discharged when the piston is moving at its slowest just at or near the dead point. A large mass of water filling a greater length of the cylinder cannot be dealt with by relief valves, because the piston motion is so much more rapid at the time the relief valves are called on to act and the water cannot escape fast enough to prevent a breakage. Some years ago when relief valves of the short-weighted lever type were tried they acted, but they only acted once. The call to act was so sudden that the valves lifted and let out the water, but the weights did not lift. They remained stationary, or nearly so, and the levers bent under the sudden pressure of the valves.

Experience seems to have shown that water tends to find and travel along the lower side of a pipe, and water being heavy and devoid of any potentiality of movement in itself, it follows that law of motion which tells us that a body in motion tends to keep in motion in a straight line if unacted upon by any external force. Steam can of itself turn a sudden corner. Hence in a square bend pipe the water rushes forward past the bend and may be caught.

In a pair of engines supplied from one steam pipe it is common knowledge that the first engine has fairly dry steam, while the second only a few feet further gets all the water. This is but the action of the above law, and the fact that steam pipes are generally fixed so as to provide that the water shall travel all the way with the steam, is a proof of the little grasp of laws which the system of teaching mechanics gives to our engineering students. In the fixing of exhaust injectors better working is always secured when the pipe to the injector springs squarely from the exhaust pipe, for thereby it snatches dry steam, and the water and also the oily particles rush onward.

The danger of carrying the water at too high a level in a boiler is not perhaps so dangerous in boilers of large water surface area as in the small steam drums of water tube boilers in which probably it is easier to set the water in motion. Some safeguard is desirable against too high a water level, but this alone will not protect engines. The only safeguard is a sufficient separator, and as dry steam is always so much more economical than wet steam, the expense of a separator will very soon be returned.

ON SOME RECENT INVESTIGATIONS IN CONNECTION WITH THE ELECTRO-DEPOSITION OF METALS.*

By J. C. GRAHAM.

(*Continued from page* 320.)

Now, going back to the Diagram D, the first vertical column on the left hand under the fig. 1 shows the behaviour of an anode the same size as the cathode, when connected to one cell, two cells, three cells, &c., up to six cells. The second vertical column under the fig. 2 shows the behaviour of an anode double the size of the cathode, and so on.

The observations for each square were during 10 minutes, and were made every 15 seconds.

It will be noted that although the amperes which passed just at the moment when the current was switched on were pretty nearly in proportion to the electromotive force, the amperes which were passing after an interval of 10 minutes did not follow this proportion even approximately:—For example, the terminal amperes with one cell were about $1\frac{1}{4}$, and with six cells they were only about $2\frac{1}{8}$, with an anode the same size as the cathode.

It will also be seen from Diagram D that as the anodes became larger, the difference between the initial and the terminal amperes decreased, but with an anode eight times the size of the cathode the terminal amperes when working with six cells were only 80 per cent. of the initial amperes; that is to say, there was a drop of 20 per cent.

Although no gases appeared to be formed on either the anode or the cathode, it seemed possible that they were formed on the anode, but escaped observation, and that the fall in the current density might be due to this cause.

In order to test this hypothesis, lead anodes were substituted for copper ones, because it could be predicted with certainty that gas would be formed on them, and if the shape of the curves was due in any way to the formation of gas, it might be expected that the curves with lead anodes would exhibit all the peculiarities of the curves with copper anodes, but in a more marked degree. This, however, turned out not to be the case. This is shown in Diagram D_1, where the red line shows the current passing through a lead anode of the same size and shape as the copper anode which produced the black line. Clouds of gas came off the anode during this experiment. The broken lines in the columns 1 and 3 of Diagram D show the currents produced when lead anodes were substituted for copper ones at various voltages.

* Communicated to the Royal Society.

On looking at the broken lines where one cell was used, it will be seen that the current passing through the lead anode is less than that which passed through the copper one, the reason no doubt being that the lead produced a back electromotive force which was a large proportion of the electromotive force of one cell; but if the current passing through the lead anode when six cells were used be contrasted with that which passed through the copper anode, it will be noticed that the lead anode, notwithstanding the back electromotive force, allowed nearly three times the number of amperes to pass. This is clearly shown by Diagram D_1. And in all cases the current passing through the lead anode remains tolerably constant, and never shows the tendency to decrease which is apparent when copper anodes are used.

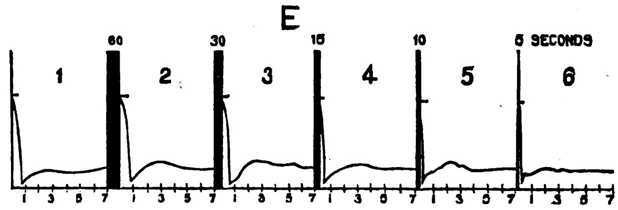
The drop in the current in the latter case can hardly be accounted for by polarisation, as this ambiguous phrase is ordinarily understood, for the drop is almost absent where the polarisation is the most perfect. In some experiments, which will be referred to later on, this drop disappeared where the anode was well washed by a rapid flow of the electrolyte. This rather points to the conclusion that it is due to the formation of sulphate of copper, which may take some time to dissolve.

It should be stated here that the curves shown on Diagram D_1, merely show the curves obtained in these particular experiments. These curves would probably change in form with any change in the shape of the anode, or in the distance of the anode from the cathode, the density of the solution, &c., but would maintain their characteristic peculiarities, viz., a sudden drop, followed by a rapid partial recovery.

The copper anodes show a tendency to blacken when small currents are passing, and become perfectly bright when dense currents are passed through them. Repeated experiments, however, showed that this had very little, if any, effect on the shape of the curves. Dense currents were passed through anodes which had become quite black, and small currents through anodes which had been made bright, and the curves were, practically speaking, the same, whatever the condition of the anode was at the commencement of the experiment.

The copper anodes also exhibited a capacity for rapid recovery. If the current, after it had come to its ultimate density, was switched off for a short interval, and then switched on again, the initial amperes were found to be almost the same as they were at first. This is shown in Diagram E. The experiments are numbered successively

E



1, 2, 3, &c. The anode area was double that of the cathode, and in all of them six cells were used. The current passing in each experiment is shown by the black curved lines. The operation was as follows:—The current was switched on and allowed to flow for seven minutes, giving curve No. 1. It was then switched off for 60 seconds, and again switched on and allowed to flow for seven minutes, giving curve No. 2. It was then switched off but for 30 seconds and allowed to flow for seven minutes. It was then switched off for 15 seconds, and so on.

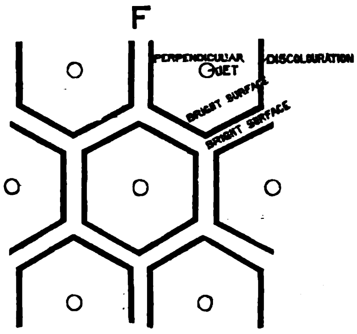
The initial amperes are nearly the same throughout, but the fall is more rapid as the time given for recovery is made smaller.

As the conditions necessary for getting fairly accurate results appeared to have been ascertained, a number of experiments were made at various current densities. It was found that with the apparatus shown in Diagram C copper could be thrown down at as high a current density as 2,000 amperes to the square metre, over a period of one hour, at the end of which time little round nodules had begun to appear.

The copper which is deposited at these high current densities does not appear to be either much harder or less ductile than that deposited at 150 to 300 amperes to the square metre. If it is deposited in the sheet form it can be doubled and opened without cracking, and if deposited in the wire form it can be drawn to any practicable fineness.

These experiments were made with a saturated solution of sulphate of copper; further experiments showed that the rate at which copper can be deposited appears to be approximately proportionate to the amount in solution. With double the

F



amount in solution the copper can be thrown down at double the rate; but accurate determinations are not possible, as there is no definite means of comparing the deposits.

Experiments were also made with a number of small jets substituted for one large one. Such jets, however, produce discoloration on the cathode along the lines where the currents meet, as shown in Diagram F, the dark lines showing the discoloured places.

(*To be continued.*)

THE "OPEN ARC" GROOVED CARBON.

The "open arc" carbon is the name which has been given to a new and interesting form of arc carbon recently brought out, and for which a number of valuable qualities are claimed, not met with in the ordinary form of solid carbons.

The distinguishing feature of this new type of carbon is a longitudinal groove running from one end to the other parallel with the length of the carbon, as shown in the accompanying figures, which we reproduce from the New York *Electrical Engineer*.

By the use of this carbon it is claimed, first, that the vortex action of the current is checked by the groove, and the crater of the carbon is held stationary at the apex of the pencil; and what is still more important, is that the size of

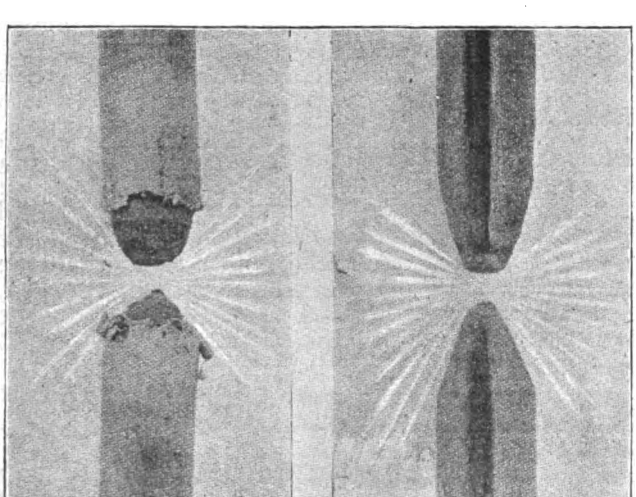


Fig. 1. Fig. 2.

the white light crater is nearly double that of any other carbon. This is explained by the inventor thus: With the solid or cored carbon that part of the white light crater is only visible which is on the apex of the carbon; with the grooved carbon, however, the crater appears as well on the sides of the segment cut out of the carbon as on the end, almost doubling its light rays.

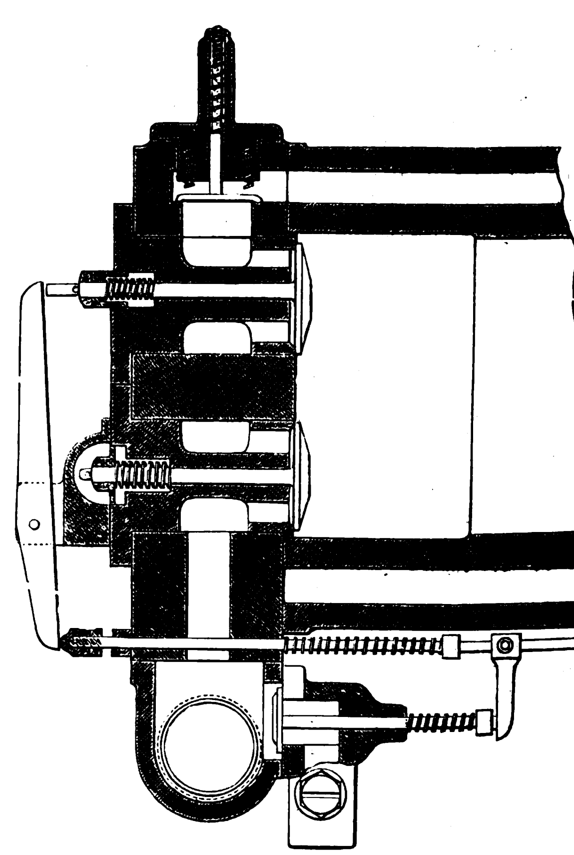
It is also claimed that with a solid or cored carbon, the maximum heat point is the centre of the carbon, hence, the centre of both carbons disintegrates too rapidly, leaving walls on either side which, a large portion of the time, obscure the crater, and build up on the lower carbon to a point that shuts off the rays from travelling downward. With the "open arc" carbon, it is claimed that the grooves cut the material from the centre, leaving nothing there, and throwing the maximum heat point to the sides of the pencil, thus giving the lower stick a cone-like form, and allowing all the rays to travel downward.

The accompanying figure illustrates this action, and was made from photographs taken from two sets of carbons burning side by side in high tension lamps, both sets of carbon being coppered. Another point made, is that a ⅝-inch carbon, solid or cored, while desirable for a long run, is a poor light developer; but with the "open arc" carbon, this result, for the reasons before given, does not obtain.

This new form of carbon is said to increase the illuminating power of the arc from 30 to 40 per cent., without any increase in current consumption, and if this be so it unquestionably has claims to recognition. We may add that the new product is being introduced by the Open Arc Carbon Company, of 108, Fulton Street, New York, and that a number of prominent electrical men are interested in the company, among them Mr. Charles A. Lieb and Mr. Caleb H. Jackson.

THE WHITE AND MIDDLETON GAS ENGINE.

This engine is of American make, and can be seen at 29, Queen Victoria Street, the size of this special engine being 6½ inches × 15 inches, to develop 13·6 I.H.P. and 12 B.H.P.

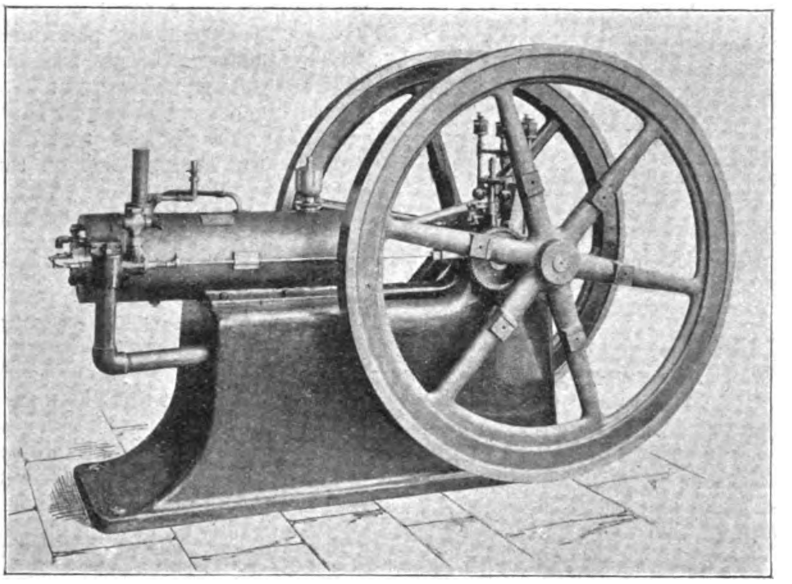


Like most engines of to-day, it is worked on the Otto cycle, but it is modified from most engines by the possession of an exhaust port at the forward end of the cylinder, which is uncovered by the piston on its extreme outward stroke, and thereby the ordinary exhaust valve is made much smaller and exposed to much less wear, only about a tenth of the exhaust escaping this way. The ordinary trunk piston is used, but has no rings. Ignition is by incandescent tube.

The valve gear is driven by small spur gears from the crank shaft. It consists of a revolving cam which drives a push rod through the medium of a friction wheel swung into contact with the cams by the governor. When the wheel comes against the cams the gas valve is opened.

When seen by us running light, the engine only required one explosion to run it on an average fully 15 revolutions. Indeed, the running was remarkably good and easy, and the engine is well made and neat in design.

Tests reported in the maker's catalogue show a consumption of only 16 feet of New York gas per brake horse-power-hour. The floor space occupied by the 12-H.P. engine is 7 feet × 2 feet 9 inches, and the fly-wheels, of which there are two, are 4 feet 8½ inches diameter. The belt pulleys are arranged to be screwed against the side of the fly-wheels, thus avoiding extra length of shaft, and avoiding stress on the fly-wheel keys to some extent.



White & Middleton Gas Engine.

The engine is readily convertible into a gasolene engine by removing the gas inlet, and substituting a small oil pump with electrical ignition in place of the ignition tube. The exceedingly neat and simple external appearance of the engine, and the absence of gearing and projections generally, give to it a very pleasing appearance. It gives a good indicator diagram, and is altogether a very good and well made machine. The forward exhaust port is, we think, an item that might be adopted with advantage in other engines.

KINGSLAND'S SURFACE CONTACT SYSTEM OF ELECTRIC TRACTION.

There appears to be a feeling at the present time among tramway experts, that the "surface contact" system is likely, under some circumstances, to come into limited use. It is noticeable that in America, which is greatly ahead of this country in tramway work, there is a disposition to adopt in some places a form of conduit system.

In many towns in this country where the "overhead" has been adopted it has been so because it was felt to be, so far, the only system which had proved an undoubted commercial success; but in most cases a reliable underground system, had such been available, and inexpensive in first cost, would have been welcomed.

The "open conduit" or "slot" system has not proved itself to be a serious competitor to the "overhead"; its disadvantages are many and its expense great. There remains the "closed conduit," or "surface contact," system; in which the whole of the conductors and other electrical apparatus is put underground, and the current is collected by the car from a number of surface contacts or studs placed at intervals along the track, their distance from each other being approximately the length of a car. These studs must be cut in and cut out of circuit as the car advances from one to another, and there must be no chance of any one stud being left "alive" after the car has passed it.

What may be called the intrinsic disabilities of the "overhead" and the "slot" systems respectively, do not pertain to the "surface contact" system; and there is in reality only one qualification to be demanded from it, and that is its reliability. The question is, can the automatic switches which are required to cut in and cut out the various sections or surface studs be relied upon to fulfil their functions with a minimum chance of failure?

The various patented devices for these automatic switches are very numerous, but the invention of Mr. Wm. Kingsland is claimed to possess some novel and interesting features which have not been hit upon by previous inventors, and which are stated to give the system some decided advantages which will readily be appreciated from the following description of the apparatus and method of working.

Fig. 1 is a diagram showing the main principle which is followed in the arrangement of the conductors and switches. M M is the main conductor, R R the rails, and S R^1, S R^2, S R^3, S R^4 are the sectional rails, or surface contacts, from which the current is collected by the car, and which may be simply studs instead of rails, as shown in the diagram. S^1, S^2, S^3, are three switches, each of which consists simply of a lever, *l*, which operates a sliding contact bar, the function of the bar being to connect the two contact springs, *a* and *b*, or the two similar contacts, *c* and *d*. It will be seen that when the levers are all in one direction, connecting, let us say, the contacts, *a* and *b*, of each switch, there is no electrical connection between the main, M, and any one of the surface contacts, S R^1, S R^2, &c. But if the lever, *l*, be moved to the right so as to separate *a b* and join *c d*, then there will be an electrical connection between the main and the surface stud, S R^2. Now let us suppose a car to be on

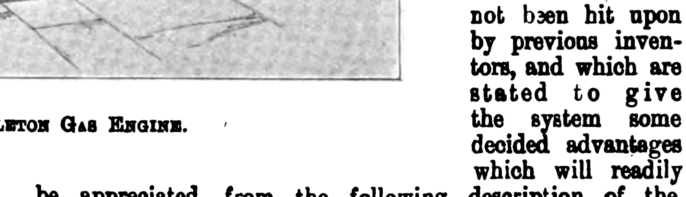


Fig. 1.

S R^2 and moving towards S R^3. When it reaches the lever, l^2, it will carry it over to the right, thereby opening *a b* and closing *c d*. The opening of *a b* disconnects the surface stud, S R^2, and the closing of *c d* connects the following one, S R^3. An advantage is said to be gained by this arrangement because it is only necessary to operate each switch once; that is to say, that after a car has left a switch, the switch has not to be operated again in order to break the circuit, as that is done by the action of the succeeding switch. In this way one-half of the difficulty of making a reliable switch is overcome, as the switch does not require to be held in position by any force, electrical or mechanical; it has simply to be moved to one position or another and left there.

A simple system of lever switches, however, will not be available for ordinary street work, and it becomes necessary to devise some means whereby the switches shall be operated electrically and automatically. This is accomplished by the action of a cylindrical commutator, which is partially rotated, or rocked, by means of an electro-magnet.

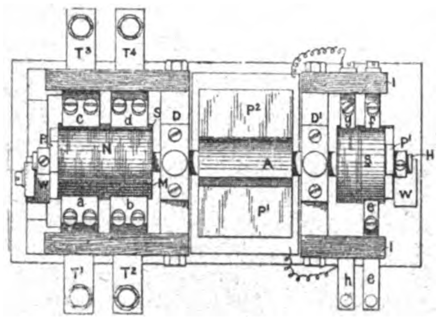

Fig. 2.

Fig. 2 is a plan of the apparatus. P^1 P^2 are the pole-pieces, and A is the armature of an electro-magnet, which is shown in elevation in fig. 3. N is a cylinder of insulating material, revolving loosely on the same spindle that carries the armature A. On part of the surface of this insulating cylinder are two metal plates, one of which serves to connect the contact springs *a* and *b* on one side, while the other will connect the contacts *c* and *d* on the other side. When *a*

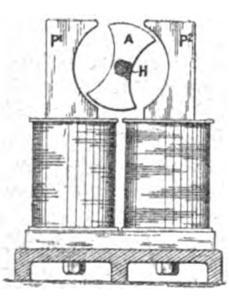

Fig. 3.

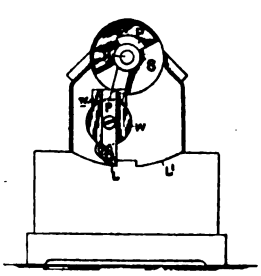

Fig. 4.

and *b* are connected by reason of the movement of the cylinder, *c* and *d* are disconnected, and *vice versa*, but the one pair cannot be disconnected until the other pair are connected, and thus there cannot be any sparking whatever at these contacts.

When the electro-magnet is energised, the armature will be turned to a horizontal position, and in turning will turn the commutator, N. This is effected in the following way. The spindle H, fig. 4, has attached to it the counterweight, W. The spindle is rigidly attached to the armature, A, fig. 3, but as already stated, the commutator, S, is free to revolve upon it. Part of the insulating cylinder, S, is cut away, and a quadrant projection, P, is fixed to the spindle, H. When, therefore, the armature of the electro-magnet is moved from a vertical to a horizontal position it will be able, on the one side, to move the commutator through a quarter turn, but on the other side, it will not do so, because of the half which is cut away. This cut away portion, however, permits of the armature returning to its normal vertical position as soon as the current in the electro-magnet ceases. If the armature were allowed to come to rest exactly in a vertical position, it would be attracted neither to one side or another when the magnet is energised, but it is prevented from doing this by means of a catch, L, at the end of the counterweight, W. The momentum of the counterweight carries it a little past the vertical position, and it is prevented from returning by the action of the catch on the raised portion of the plate, L^1. The result of this is, also, that the next time the magnet is energised the armature is certain to be attracted in the opposite direction, and thus an alternate motion from side to side is ensured.

The action of the electro-magnet is controlled by means of a small commutator, S, fig. 2, placed at the other end of the spindle, H, and working in exactly the same manner as the large commutator. The contact springs on the small commutator are so arranged that the electro-magnet can only be energised if the switch is set in the opposite direction to that which may be required for any particular surface stud.

The circuit through the electro-magnet is a shunt one, on the main conductors, one end of the coil being connected with a surface stud through the small commutator, and the other end to earth. The car, in passing along the track, makes contact with one surface stud before it leaves another. As soon, therefore, as it makes a contact with a stud in advance the current can pass down from that stud, through the electro-magnet of the corresponding switch, which will thus be operated, and will cut in the new surface stud and cut out the one which the car has just left.

It will now be seen that the system is fairly simple, both in the arrangement of the conductors and in the mechanism of the switch. The action of the switch is a simple rocking movement on one spindle, and there is no force required to keep the switch in position, as it is a simple change movement, and not a make and break. Moreover, the pressure of the contact brushes on the commutator is always the same, and is not affected in any way by the action of the switch. Another immense advantage lies in the fact that there are no working springs whatever, in fact it is difficult to see what there is in the switch which can possibly get out of order.

The switches are made to go into a cast-iron box 8 inches × 10 inches, with watertight covers. The cable connections pass in through watertight glands, and are so arranged that they can readily be disconnected, and the switch lifted out

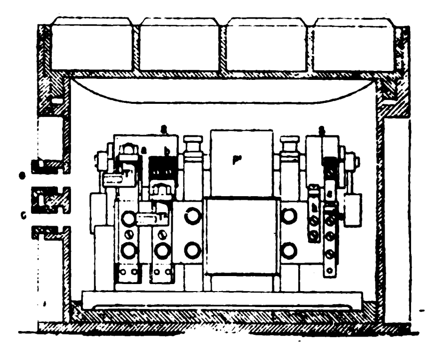

Fig. 5.

for inspection. Fig. 5 is a view of the apparatus in its box.

We suppose that it is impossible to make any apparatus which shall absolutely never fail. In this system, if a switch should happen to fail, the car could not proceed, and therefore the failure would be immediately discovered. It would be the work of a few minutes only to open the box and rectify or change the switch.

With this system the car is not required to carry any equipment in the way of electro-magnets or storage cells with which to operate the switches, and therefore it offers facilities in working the same cars on the overhead as well as on this system, as, for instance, where an underground system is required in a town, working in conjunction with an overhead in the suburbs.

The British and foreign patents for this invention are owned by Messrs. Kingsland & Edwards, of Manchester and Llandudno; and those who are interested in the matter may see the apparatus, which is now on exhibit at the Electrical Standardising, Testing, and Training Institution, Faraday House, Charing Cross Road, by written appointment to that address.

THE EMPIRE AND TELEGRAPH CABLES.

(*Concluded from page* 289.)

We have dealt with some of the more prominent of the objections which are now being revived against a cable through the Pacific. The "enormous depths" of this ocean, it will be seen, are now discounted, and we even find it put forward, with an austere assumption of impartiality, that the great depth of water through which the Cape cable must pass would obviate the serious danger of interruption to which the existing lines to Australia are exposed in the shallow Java Sea. We quite agree with the opinion expressed that the present cables which pass through the Mediterranean would probably be rendered useless in case of warlike complications, as this did actually happen during the Egyptian war; but we would go still further, and point out that the same objection applies with equal force to several sections along the proposed Cape route, which, in places, would necessarily have to lie in very shallow water, and where they could be easily cut by the enemy. Take, for example, the section which would pass off Brest, where, for more than 150 miles, all the existing lines to Africa and the East are in water of less depth than 100 fathoms; and through this dangerous belt it is now seriously proposed to lay a strategic cable! In the case of the Pacific scheme any such danger is quite avoided.

To turn to another aspect of the new "supplementary" scheme, we find that to carry it out, some 13,700 miles of cable would be necessary, to which should be added 1,000 miles of landline from Cape Town to Natal. We also find that the cable would be landed in no less than 11 different places—almost all points of weakness—the last being the town of Perth in Western Australia. As opposed to this, we find, in the Pacific, that the length would only be 7,500 miles, and the landing places only five in number, lying in a part of the ocean little frequented by foreign vessels of war, the cable terminating between the towns of Sydney and Brisbane on the east coast of Australia. Should the cable bifurcate from Norfolk Island to New Zealand, an additional length of 450 miles will be necessary, and an additional landing place will be created. In continuation of this comparison, it should be borne in mind that the two existing cable routes to Australia converge at Java, and bifurcating thence, end; one at Port Darwin in the north of Australia, the other at Roebuck Bay, in the north-west of Western Australia. Thus we find that, to reach the centres of the greatest population, which lie in the east and south-east of the continent, telegrams have to travel over very great lengths of landlines. In the case of the Roebuck Bay cable there is a distance of about 3,300 miles to be traversed from that point before even Melbourne is reached, and more than 4,200 miles (about half the length of the Pacific cable!) before Brisbane is reached. Again, a telegram *viâ* Roebuck Bay, destined for the town of Burketown, in Queensland, has to travel over a length of landline which is greater than the distance between London and Calcutta, or several hundreds of miles more than the distance intervening between London and Vancouver. The land wire from the Port Darwin cable station is not so long, giving about 2,400 miles to Melbourne and 3,300 miles to Brisbane. It is now, we are told, proposed to land the "Cape" cable at Perth, the capital of Western Australia, which is more than 2,000 miles by landline from Melbourne, and over 3,000 miles from Brisbane. On the other hand, in the case of a cable landing on the Pacific coast of Australia, the main centres of population and commerce are within easy reach, Melbourne being only about 450 miles south of Sydney by landline, while Brisbane is about 520 miles to the north. The great importance of these figures will be at once evident, when we realise that the long landlines from Port Darwin and Roebuck Bay, the only means by which telegrams from Europe can be forwarded at present, have been interrupted on no less than 15 occasions during the last six months, the duration of each of these interruptions varying from a few hours to several days. In speaking recently of the Roebuck Bay landline, Sir Charles Todd, the Postmaster-General of South Australia, says, it "is acknowledged to be the worst line in Australia, the many fogs on the coast rendering it very hard to get signals through." It is thus clear that a Pacific cable would offer advantages which cannot reasonably be looked for, neither in the case of the existing cables, nor in that of the proposed cable from the Cape. The landlines in the compact group of colonies, Victoria, New South Wales, and Queensland, are numerous, and here reliance has not to be placed on long single wires, as in the cases above referred to. Duplicate communication with New Zealand can be easily assured by a short branch cable from Norfolk Island. The advantages above indicated are obvious, if we consider that the population in the south and east of Australia is about 4,200,000, who carry on a total export and import trade equal to about £120,000,000 annually, employing for this purpose some 17,000,000 tons of shipping. It would, therefore, seem beyond dispute that a cable landing right in the heart of this busy district is much more to be desired, and is much more worthy of support than one which would terminate in Western Australia; in which vast area (11 times the size of Great Britain) the total population, although increasing, is less than that of the town of Cardiff, and the trade and shipping correspondingly small, the exports and imports for 1896 being valued together at something over £8,000,000.

We propose to touch but lightly on the financial side of the question. We were informed through the press that the cable to be laid, *via* the Cape, is to be carried out in return for "certain privileges." Some light has recently been thrown on the nature of these privileges; one of which seems to be the payment of £25,000 per annum by the Cape Government for 20 years; another being the prolongation of the annual subsidy of £32,400 which has been paid by the Australian Governments to the Eastern Extension Telegraph Company since 1879, and which, if not renewed, will lapse in July, 1900. There may be other concessions which have not yet come to light.

It is a question whether the limits of modesty are not being overstepped, when we remember that one of the companies concerned, *i.e.*, the Eastern Extension Telegraph Company, has already received from Australasia, subsidies amounting to over £750,000; and that in the 10 years ending December, 1896, the annual receipts of this company, which are now about £640,000 (including subsidies), have increased by £187,459, and this notwithstanding a reduction in rates of about 50 per cent., which was only brought about under great pressure. An allied company, the Eastern and South African Telegraph Company, of which almost the entire capital is held by the Eastern Telegraph Company, has received in subsidies from various governments a total of considerably over £1,000,000.* It is not, perhaps, a cause of wonder that even a far-fetched attempt should be made to secure the continuance of similar "privileges," but we do not think that it is at all in the interests of the Colonies, or of England, to assist in the consolidation of any such monopoly.

We have dealt at this length with the subject, as it seemed only fitting and just that, however useful a cable to Australasia, *via* the Cape, may be, the claims to superior utility, both strategic and commercial, of a cable *via* Canada to Australasia should not be undermined by the circulation of misleading information.

CORRESPONDENCE.

Accumulator Testing.

Although your article on "Comparing Results of Tests on Accumulators" contains several hints to those engaged in testing accumulators, the writer seems to have omitted many equally important considerations.

If the accumulator is intended for lighting purposes, where constancy of voltage is imperative, it should in all cases of comparison be stated how thick was the acid space, or the distance between the plates.

Your contributor will find a marked increase in the steadiness of the pressure line with every fraction of an inch increase in the distance of the plates up to a limit ascertainable only by test for each kind and thickness of plate.

This is true of all lead storage batteries, but is, of course, most marked in those of the pasted type.

If the accumulator be intended for traction purposes, the acid space may be small, because a fall in pressure merely means a reduction in the speed of about the same percentage as is the fall in pressure.

One other point out of those named is the incorrectness

* The Aden-Zanzibar cable belonging to this company was interrupted all last week, thus completely cutting off the Cape from communication with Europe by the East Coast of Africa route.

of the assumption that the result from one positive can be used, all other things being equal, for accurately ascertaining the capacity, &c., of a complete battery.

Let your correspondent take three positive and five negatives of similar type and make them up into two cells of one positive and two negatives and two positives and three negatives respectively, and he will, after a few trials, see fit to modify his statement.

Even so far, however, as your correspondent goes, his article contains much that may be carefully followed by inventors and experts when testing batteries, and it may ultimately come to be understood that no two kinds, or even arrangements of the same kind of plate, will give results which can be tabulated on one basis, either of total weight, weight of single plates, weight of acid, or weight of so-called active material.

Appak.

Crowdus Storage Battery.

Referring to your article in the last ELECTRICAL REVIEW, I consider practical work of far greater value than academical figures. Some of these cells are now on the way here, and I shall be pleased to allow you, or your engineer, to make your own tests. Meanwhile, a perusal of the enclosed detailed description may be interesting to you. By letter just received from Mr. Crowdus, he states:—

"It seems almost incredulous, but these waggons have been going six days a week through the severe snows of the past two months, and in blizzards that severely crippled all kinds of traffic."

The waggon referred to is on page 16 of enclosed catalogue, which please return.

John T. Bowden.

[The figures called academical are unfortunately Mr. Crowdus's own figures. We also prefer practical work, and nothing can be more practical than careful, accurate, tests of a battery by a competent engineer. There are doubtless many professional experts to be found ready to test and report on this battery, and if the claims made for it can be supported by any one or more of these gentlemen, we shall be the first to congratulate Mr. Bowden. We publish on p. 381 the description referred to, from which it may be gathered that the cell is just what we all know as a pasted plate cell. The use of sulphate of zinc in the solution, and aluminium for the negative support, are doubtful improvements; at any rate, they require investigation by independent experts before being accepted as such. There is nothing surprising in driving waggons by electricity; it is easy enough if we put in plenty of cells of large enough capacity; but what we took exception to was Mr. Bowden's "academical figures," that waggons were driven 50 miles by a $3\frac{1}{2}$ horse-power motor, with 44 cells of 100 ampere (hours) capacity; such an incredulous claim requires more support than the bare statements of the inventor. Mr. Bowden has put nothing before us of the slightest value in support of the extravagant claims made for his battery.—EDS. ELEC. REV.]

Parabolic Reflectors—An Anticipation.

I notice under the heading "The Institution of Electrical Engineers," an abstract of a paper entitled, "An Electrolytic Process for the Manufacture of Parabolic Reflectors," by Sherard Cowper-Coles.

I was quite interested in the account given, inasmuch as I practised substantially the same method of producing metal mirrors a number of years ago, and have the specimens of work now in my possession. My method was the same as that described in the paper referred to, viz., to take a glass surface, highly finished, and of the form of the reflector required, deposit upon it a silver coating, by any of the well-known silvering processes, such as are used for glass specula; follow this deposit by a heavy coating of copper, electrically made; separate the glass from the deposited metal; and, when needed, coat the face of the mirror with nickel or other metal resisting oxidisation or tarnish.

My object in developing the process was to replace the glass mirrors of searchlights, which are very easily fractured, but the process is undoubtedly a good one for making any accurate metallic mirrors.

I have had the silver coating leave the glass in such a high state of finish as to present the appearance of a vitreous surface. The least blemish or scratch in the glass surface is reproduced in the silver coating with absolute fidelity. I found that an easy way of separating the metal from the glass was by warming; the metal being more expansible than the glass readily separated when the warmth was sufficient. The deposited silver coating must be as free from pores as possible, otherwise there is a tendency for the copper-plating fluid to insert itself between the glass and the silver and blister.

Elihu Thomson.

March 2nd, 1898.

Sparking Coils.

Apparatus of various kinds for producing very long sparks have been lately described in your columns. I notice that in every case, while the length of spark is carefully stated, no measurement of the quantity of electricity yielded seem to have been made. The outputs were apparently guessed at. I designed some two years ago a simple instrument for measuring the quantity of electricity yielded by spark coils and similar apparatus.

In its simplest form it consists of a sensitive thermometer, on the bulb of which a small bobbin of thin insulated platinoid wire is mounted. The current from the secondary is passed through the bobbin for a known length of time, and the rise in temperature is noted. The heating effect may be taken to be proportional to the square of the current multiplied by the length of time the current has been passing. The instrument can be calibrated by passing a known current from a battery through the bobbin.

I have found that this instrument throws much light on the actions which take place in the various parts of the secondary winding.

G. Bowron.

March 14th, 1898.

"The Burning Question."

An original dissertation in the pages of the ELECTRICAL REVIEW, on the treatment of sewage sludge, could not fail to make very interesting reading, and I am sure you will not take offence if I add that the article on this subject, under the above heading in your issue of the 25th ult., is not merely interesting, but very amusing also. I hail the appearance of the article with great satisfaction. When the ELECTRICAL REVIEW voluntarily devotes so large a portion of its valuable space to a careful, even if utterly erroneous, investigation into problems connected with the disposal of refuse, and sewage sludge of all things, I feel convinced the time is not distant when the refuse destructor, which has hitherto, as you will allow, often received rough, and even disdainful, handling in the electrical press, will frequently find an honoured place in your pages. I do not mind even if your present article appears adverse in any way to a particular type of destructor with which I happen to be associated, when used for a particular purpose. It is sufficient for me that you are really investigating. Soon you will "discover" the refuse destructor, and we shall all be happy.

Meanwhile, you will recollect a description of a group of individuals who, if I remember rightly, "sat apart upon a hill retired," pursuing certain abstruse speculations, and became "involved in wandering mazes lost," and I greatly fear you also have become a little involved in your investigations in connection with sewage sludge. I am consumed by a desire to put you in the right path, therefore I beg to ask your reconsideration of the following proposition which occurs early in your article. The italics are mine. "The cost of burning is 1s. $6\frac{1}{2}$d. per ton of pressed sludge. *Assuming that one-third of the weight of wet sludge has been removed by pressing*, this would amount to, say, 1s. per ton of wet sludge." This assumption is so delightfully naïve, that one hesitates to disturb it; but stern logic compels. I am obliged to inform you, therefore, that every ton of *pressed* sludge at Leyton represents eight tons of wet sludge; and instead of the "weight removed by pressing" being "one-third," as you artlessly assume, it is more than 87 per cent; instead of being only *one-half* that of the pressed sludge, it is seven times as much. There is no mystery about it. The moisture in the *pressed* sludge is 60 per cent., in the wet 95 per cent. One of your young men would check the calculation. Consequently the cost of burning, when expressed in terms of the weight of the wet sludge, instead of being 1s., as you have estimated, is a fraction over 2½d.

You will easily see the absurdity of attempting to express the cost of any such process as the burning of pressed sludge, in terms of the wet sludge, if you consider that the moisture in the latter may vary immensely without making any appreciable difference to the cost of pressing, and none at all to the cost of burning. Thus, in the figures that you quote from Sir Alexander Binnie's report, the moisture in the wet sludge at Barking and Crossness averages about 91·00 per cent. Now, if this sludge were pressed as at Leyton, every ton of the pressed material would represent rather more than 4½ tons of the wet; the weight removed by pressing would be 77 per cent., or three and a half times as much as the weight of the pressed residue; and the cost of burning would be 4d., or 60 per cent. more than at Leyton, *expressed in terms of the wet sludge. The real cost of burning the material actually put into furnaces would be the same in both cases.* Of course, the impressive fabric which you have built upon your "assumption" must now come down.

"London," if she wished to press and burn her sewage sludge, would not require to expend anything approaching the extraordinary sum at which you have arrived. As a matter of fact, I do not know that anyone is seriously proposing that "London" should press and burn her sewage sludge. If at the time the present system was adopted by the late Sir Joseph Bazalgette, after a most complete series of experiments upon the pressing of the sewage sludge, one of which was adopted at my suggestion and superintended by myself on behalf of an eminent firm of Scotch engineers —if at that time there had been a destructor furnace whose capabilities in regard to the burning of sludge cake had been demonstrated like those of the Leyton furnaces have now been demonstrated; if also the question of destroying house refuse had attained the importance it has now acquired, then the problem of getting rid of the house refuse of London, or more particularly of the river districts, by using that refuse in that way to destroy the sewage sludge, thus getting rid of two huge nuisances at one stroke, would have been well worth the consideration of the authorities of that time. Even as it is, the possibility of such a combination is probably still worth the consideration of Sir Alexander Binnie. Leyton saves over £300 a year in coal in operations in connection with her sewage. The same rate would not apply to Barking and Crossness. If it did, over £18,000 per annum might be saved there; but, anyway, Sir Alexander Binnie could get all his mechanical operations at the Outfall Works done for a mere fraction of his present expenditure on coal, and have something considerable to spare. The idea is not new; Mr. Jones, of Ealing, I believe, proposed it at one time. But "it were well 't were done quickly." London refuse is rising in value. Soon none will be available for burning sewage sludge; it will all be in demand for producing electric light and power.

There are other texts in your article upon which I would have liked to descant, but I fear I have trespassed too much. I would, however, as you have referred to Mr. Jones, of Ealing, like to express my personal regret that there should have been the appearance, in connection with the recent celebration at Leyton, of a deliberate ignoring of Mr. Jones's claims in connection with the burning of sewage sludge. However crude one may consider the process at Ealing to be, it is unquestionable that to Mr. Jones belongs the credit of having first destroyed sewage sludge by burning upon a practical scale, and this acknowledgement is no more than the merest justice to him.

A. J. Liversedge.

March 3rd, 1898.

P.S.—The above was written before the appearance of Mr. Hetherington's letter in your issue of the 4th inst. Mr. Hetherington has put you right in reference to the "weight removed by pressing sewage sludge," but seems to have fallen into a remarkable misapprehension, to judge from his delightful account of what he imagines to take place at Ealing. He is not apparently aware that whilst the wet sludge is not "pressed" at Ealing as it is at Leyton, it is *drained* through house refuse—Mr. Jones devotes a certain proportion of his refuse to that purpose. What is the exact proportion of water so removed has not, I think, been stated. It will not, of course, be so much as the amount removed by pressing; but it is sufficient to bring down the process from the realms of the alchemist, where Mr. Hetherington appears to think it properly belongs—well, something after the prosaic style of Leyton.—A. J. L.

Rubber Cables.

The manager of the Burton-upon-Trent Gas and Electric Light Works a few weeks ago issued a circular to his colleagues of other towns. In this circular he stated that India-rubber covered cables of our manufacture had given him considerable trouble. As a letter of this description was likely to prejudice this company in the eyes of many, if dealt with as a confidential document, we had the circular reprinted and distributed, asking the recipients if they would take the trouble to furnish us with any replies they may have made to the original document. We have to thank a number of these gentlemen for their courtesy in replying. In answering, many informed us that they had not received the circular in question, others either had not replied to it, or were not users of our cables. Among the replies received from the users of our cables, six stated that they had some trouble either with the small or with the arc lighting cables, and in the majority of these cases the trouble was only temporary. Two wrote that they had no trouble whatever of a serious character, and the remaining 10 wrote that they had absolutely no trouble at all.

From the number of definite replies, we are well aware that these do not include reports from all the users of our cables for high tension distribution, as in some cases, where there was no cause of complaint, no replies were made, and, in other cases, where there has been, or may have been, trouble, we were not favoured with a copy of the report, if any, which was sent to Burton.

We hold that the statement reported to have been made by Mr. Alderman Lowe, of Burton-upon-Trent, and referred to in your issue of the 18th ult., must be incorrect, as the answers received to our circular show that, out of a total of 18, in 12 cases the cost of maintenance has been practically *nil;* and, as to the others, we understand the cost of maintenance has in no case been large.

We trouble you with this letter as the matter certainly is of importance to ourselves, and we believe it to be of interest to electrical engineers.

Wm. Gray,

Electric Light Department, The India-Rubber, Gutta-Percha, and Telegraph Works Company, Limited.

Knots.

Having read Mr. Little's letter carefully I fail to see that the expressions "60 knots in length" and "12 knots per hour" are "inexact and wholly unscientific," and beg to differ when he says a *knot is a speed.* A knot is a measurement arrived at as follows: The circumference of the earth, 131,385,465 feet, is divided into 360 degrees, each degree being again divided into 60 parts or knots, consequently

$$\frac{131,385,465}{360 \times 60} = 6,082{\cdot}66 \text{ feet} = 1 \text{ knot},$$

6,080 feet being the length of the Admiralty knot.

A knot per hour is a speed expression in the same way as the expressions miles and miles per hour denote distances and rates of speed travelled by trains or other vehicles on land.

Mr. Little says the "word knot is used to denote an interval (length) between one or more marks on the log line." A log line being a length of line divided by knots spaced at intervals of about 50 feet, this spacing being chosen when the sand glass (used in taking speed measurements by this method) runs for 30 seconds, 50 feet bearing the same ratio to the length of a knot as 30 seconds does to an hour, viz., $\frac{1}{120}$th part (50·68 feet would be correct) but the fractional part is not considered as it is allowed for the wash of the wake of the vessel. Thus the log line is a measurer of distance, as when in use the log ship (a triangular piece of wood weighted to keep it in a vertical position) remains stationary and the line is allowed to run out freely, the operator counting the knots in the line as they run through his fingers or over the rail, the number of knots which are counted being the number which have run out whilst the sand has been running through the glass for 30 seconds. This, of course, gives the distance which has been traversed by the vessel from the place where the log ship was thrown overboard in that period of 30 seconds. The log line, therefore, merely acts as a convenient scale for measuring a short distance travelled over in a given period of time, by which the speed per hour can be determined at once.

The whole question appears to be a quibble, as Mr. Little admits the use of the word knot to denote the interval between two particular marks on a log line, but will not permit it to be used to denote a distance which has been used for scores of years by naval officers and others, including misguided cable engineers.

Another Cable Engineer.

Testing Secondary Batteries.

In the communication on "Comparing Results of Tests on Accumulators," published in your issue of last week, I notice the following statement:—

"That constant rate of watts is the correct method is undoubted, for if we use a battery for power or traction, it may be called upon to work at the same rate at the end of 6 or 8 hours as at the beginning of the run."

Now, it would be interesting if your correspondent would let us know how a battery can be used in this manner. It probably could be done by some series-parallel arrangement of the cells, but surely the ordinary way of working in nearly all practical cases is to keep the *current* constant by switching in regulating cells or by cutting out resistance coils? Thus, although the watts *given to the motor* are constant, the watts *given out by the battery* are by no means so. To test a cell at constant current, therefore, seems the best method for present day practical purposes.

Albert Campbell.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

At the last meeting of the Institution of Electrical Engineers, held at the Institution of Civil Engineers on Thursday the 10th inst., the discussion on Mr. Binswanger Byng's paper dealing with 200-volt lamps and fittings was continued and concluded. It was not concluded, however, without repeated requests on the part of the president to speakers to be brief, while many desirous of throwing the light of their experience on the subject were relegated to the sending in of written communications to be printed in the *Journal*, and even then the hour of 10 had struck and gone ere an adjournment to the less formal, but equally interesting, discussion over tea and cake, was effected.

Prior to the re-opening of the discussion, the president, Mr. J. W. Swan, announced the preparation of a testimonial to M. Gramme, that a circular asking for subscriptions thereto was in hand, and that the inventor whose work in connection with the dynamo, everyone is aware of, and acknowledges, is to be banquetted at Brussels shortly. Strange to English ears, was the promise that donors of the smallest current gold coin would receive a bronze, and givers of a larger sum, a silver medal to commemorate the event, and, we suppose, reward those who assist the subscription list.

Mr. Stearn was the first speaker on the question before the meeting, and he gave his views at length. He had little to add, and nothing to retract from what he said in the discussion on Mr. Addenbrooke's paper,* as to the principles of high voltage lamp construction, and to show the exact position he held, and holds still, he quoted largely from his remarks in the *Journal of the Institution.* He considered the double filament is the most convenient as a transitional form, but that the zig-zag filament lamp met most requirements. Considering the material of the filament, he believed it has been shown that the change in candle-power is slower with low specific resistance; with high specific resistance a shorter filament can be obtained, which has the drawback of a rapid change in candle-power. But low specific resistance filaments can be used where some means of anchoring is adopted. He still considered that the type of high voltage lamp was best for a time, which suited most closely the conditions of the transitional period. Timidity in the use of high voltage supply was, however, dying out, and opposition to the change being gradually overcome. Lamps should be durable in the first place; reliable, so that there should not be premature breakages, while they should absorb the same amount of energy that one is accustomed to with the older and better known types. That the candle-power should be the same is merely desirable, and not at first essential; but small units, such as 5 and 8-candle-power lamps, should be forthcoming.

At the time when the high voltage was mooted, we were informed that fatal accidents and fires would be likely to occur at this tremendous pressure; but confidence is slowly giving place to suspicion. The lamps and fittings to-day do not meet every possible objection; but one must walk, if not yet able to run, and it is for this reason that at the time of the introduction of 200-volt lamps, the untreated filament seemed to meet the then requirements. The light curve is not everything. Carbon of an earlier period than that of the present day was rough, cindery and fragile, and the duration of use very short indeed. Treating was adopted to patch up irregularities, and fit the carbons for commercial use. About 1881 a number of lamps were made up, half with treated and half with untreated filaments, and tested by Mr. Crompton. None of the treated filaments were readily broken, but the untreated gave way rapidly. The process, devised by Mr. Swan, of projecting a jet of cellulose into a setting solution is now generally used for the manufacture of filaments, and lamps can be made of any reasonable efficiency. Those made in this way are better and more reliable than if treated. Equal diameters and very nearly equal resistances can be depended upon. When the treating process has once been begun one is liable to variations in specific resistance, diameter and emissivity, or the radiating qualities of the surface, and changes occur from any difference in the temperature, pressure, or kind of hydro-carbon used, and many other things.

A treated filament for a high voltage lamp may be from 14 to 15 inches long, and it cannot be safely used unless some special mode of disposing of it be provided, as it really is a very flexible pendulum. But if some such disposition be not adopted, Mr. Stearn would prefer to use the untreated filaments. The fears of the public have now passed away, but they prefer lamps of long life. The factor of convenience is often overlooked. Suppose the life curve does fall, the user has the option of replacing lamps as he pleases. Mr. Stearn was surprised to hear that one lamp in a dozen was expected to short circuit at once, but this may not represent the general conception of what such lamps do. There are two causes of short circuiting: a fertile cause is the entanglement of the double filament in transit, and if this defect be not noted trouble must ensue. Another is an accidental crack in the bulb. Externally the short circuits may be due to bad capping or carelessness in using soldering fluids, or in frosting with chemicals. Internal shorts are more attributable to careless exhaustion. This should be utterly impossible. When the change was made from 50 to 100 volts, it was thought that the space between the terminals should be doubled, but later experience showed this to be quite uncalled for, and the distance between them is amply sufficient for much higher pressures if the vacuum is properly made and permanent. Mr. Stearn has not been able to discover any reason for making any difference in exhaustion or the mode of doing it. The gas to be removed is not from the filament alone, but comes, also, from the soldered ends and from the platinum.

A rise in candle-power is entirely in the hands of the lamp maker, and at one time it was thought best to do away

* "High Voltage Lamps and their influence on Central Station Practice," Mr. C. H. Stearn's remarks in discussion, p. 271, No. 122, Vol. 25, *Journal Institute Electrical Engineers*, March 12th, 1896, also *Proceedings Municipal Electrical Association*, parts of 1896 issue.

with it entirely. But rise can be kept at from 16 to 17 or 17½ C.P. in 300 hours, made to expend the excess during the useful life of the lamps. By this means a better average is obtained from the lamp during its life. Accuracy in classification, rather than cheapness in the lamps, and the maintenance of an average standard efficiency for all voltages were, the speaker believed, highly desirable. Until that accuracy is reached, lamp making cannot be an exact science.

Mr. Stearn did not see why stations should not go up to the highest pressure permitted by the Board of Trade, and even calmly spoke of 500-volt lamps for street lighting. On the question of alternating and continuous current, he suggested that if the vacuum was not absolutely perfect, lamps may last longer with alternating current. Some figures were given showing that the breaking strain for treated was less than for untreated filaments.

Mr. Crompton stated he laid out Harrow for 200-volt supply three years ago. The lamps were wholly satisfactory, and he had found no difficulties, as he had proceeded on Mr. Stearn's lines and advice. The users seemed to be as well satisfied as any 100-volt consumers, while the extreme ease of regulation and every other advantage of high voltage has been obtained. He had made tests of switches for the Council of the Institution, and at first hoped to be able to prepare a table of lengths of break for different pressures and currents, but the results proved unsatisfactory, as very short breaks on a particular form of switch gave better results than longer breaks on other patterns. He is decidedly of opinion, however, that larger covers are wanted. With fuses the perforations in the cover minimise the arcing effect. It is a very excellent idea to use plaster of Paris round the wire as Mr. Binswanger Byng does. In prescribing a twin wire one can get no further than the tests and specification given in the Institution wiring rules. It is, therefore, unnecessary for that matter to be gone into further.

Mr. Swinburne had found that one might put an N.B. into text books of chemistry to the effect that "the real chemistry may be quite different." He amused the audience by a most interesting and crisp contribution to the discussion in his best form, and our only regret is that so much is lost in attempting to convey in cold type what is so well worth listening to. He reminded those present that Ferranti had in 1885 proposed to use 500 volts, and as the representative of the Hammond Company he supposed he would have had to make the lamps had they been required. After a few remarks as to carbon, he mentioned that certain carbonised animal fibres give nearly the same resistance hot as cold. We believe we are correct in saying * that Mr. Swinburne holds the opinion that efficiency and temperature go together in lamp making. In the classical trial, Edison-Swan *v.* Holland, he was in a minority of one in this opinion, being considered as on the one hand a biassed witness, and on the other a lunatic!

Mr. Wordingham gave the results of his Manchester experience, thought small arc lamp users must not be overlooked, had received no complaints, reminded the profession of his warning that 100-volt fittings would not be safe on 200 volts, and described his tests for fuses and switches of overloading them by 50 per cent. both on current and pressure factors.

Mr. Rawlings delivered a most amusing speech on his relations with 200-volt consumers. It was painful to meet those who had gone over from lower pressures to higher, but quite a pleasure to see those who knew no better than 200 volts. Some houses have no less than four separate voltages to meet piano lamps in series, &c., and many were the troubles Mary Jane, his clients, self, and supply company had to meet. Lamps he found certainly unsatisfactory. The next speaker went into lamp manufacture in detail, and was followed by Mr. Swinton, who pictured the cathode ray lamp without a filament. He adduced the fact, not known to all, that in a high vacuum the nearer two conductors are together the greater the resistance. Even 20,000-volt lamps for street lighting, with a separate transformer to each might come.

* Mr. Swinburne later in the evening protested against a statement that he had said that efficiency depended only on temperature, which is by no means the idea he conveyed by his speech.

Mr. H. W. Miller told an unvarnished tale of certain complaints as to lack of light with high-volt lamps and the deterioration that occurs. He disagreed with the author as to the action on the blowing of a fuse, and thought that when a fuse melted the hot air and metallic vapour rushes out of the holes in a pattern such as described in the paper. Mr. Robertson stated that the advantages of carbon were so many that lamp manufacture must remain where it is until some substance other than this is found for filaments. He dealt with the controversy, treated *v.* untreated filaments, and methods of manufacture at some length.

Mr. Geipel, Prof. S. P. Thompson, Mr. Grimshaw, Mr. Addenbrooke, and the president proceeded with the debate, and then Mr. Byng rose to reply in brief. These speakers reiterated and enlarged upon the questions which had already been treated by others in part, and although what was said was extremely interesting, we think the accounts of the proceedings in the forthcoming *Journal* will be sufficient to satisfy all our readers that ample justice was done to an excellent paper.

Application for Extension of Patent.—On March 30th, at 10.30 a.m., the Judicial Committee of the Privy Council will hear the petition of the Hon. C. A. Parsons for an extension of the term of the letters patent granted to him on April 23rd, 1884 (No. 6,735), for "an invention of improvements in rotary motors actuated by elastic fluid pressure, and applicable also as pumps."

Australian Electrical Work.—From a Sydney engineering exchange we learn that the Brush Company is busy in that part of the world. The company is supplying an electric pumping plant for a Lithgow (N.S.W.) colliery company, and is now erecting electric light plant for the Sydney electric light station.

Bankruptcy Proceedings.—An application was made last Friday to Mr. Registrar Brougham, at the London Bankruptcy Court, for an order of discharge on behalf of John Orme, scientific apparatus manufacturer, Cross Street, Finsbury. The bankrupt, in 1893, promoted Orme's Electric Signal Company, Limited, to take over his patent electric fog signal. As vendor he received £6,000 in shares, which, however, proved valueless, as the company went into liquidation in 1895. He failed in November last with liabilities, £1,769, and a dividend of about a 1s. in the £ will be paid to the creditors. The failure was partly attributed to the loss and liabilities incurred in connection with the fog signal company. Three offences were reported by the Official Receiver, and the learned Registrar imposed a suspension of two years and a half.

Bankruptcy Proceedings.—Under the failure of Trehearne Son & Crump, electrical engineers and contractors, 155, Fenchurch Street, E.C., the first meeting of the creditors was held on Wednesday, at the London Bankruptcy Court before Mr. Wildy, official receiver. The accounts show liabilities £1,066, and assets, £413. The business was started by Mr. Trehearne in June, 1895, and in May, 1897, Mr. Crump became a partner, introducing a capital of £750. Disputes arose between the partners as to the position of the firm, resulting in the present proceedings. In January last an electrical engineering company was formed by Mr. Trehearne and his friends, which took over the firm's offices, and appointed him (Trehearne) as managing director with a commission on the profits. When the firm stopped there were some contracts on hand, but they were abandoned. The failure was attributed by Mr. Trehearne to losses by betting, heavy expenses incurred in getting business, loss on trading and bad debts. Mr. Crump, on the other hand, attributes it to the failure of his partner to carry out his guarantees relating to the liabilities of the business when the partnership was formed. No offer was made to the creditors, and Mr. B. T. Norton (Pratt and Norton), accountant, Old Jewry, E.C., was appointed as trustee to wind up the estate in bankruptcy, assisted by a committee of inspection.

Business Announcement.—Messrs. J. C. Lyell & Co., of 55, Victoria Street, announce that increased business has compelled them to take *all* the offices at the above address, which is now occupied solely by them. They are shortly about to open several new departments.

Catalogues.—Mr. A. P. Lundberg, of Bradbury Street, Kingsland, has brought out a catalogue which is a credit to both printer and compiler. The setting out of the cover is very neatly done, and it is printed in green and gold. In the 28 pages of letterpress and illustrations, Mr. Lundberg lays before his customers and the trade generally particulars of his numerous types of switches, wall connections, wall plugs, distributing fuseboards, cut-outs, ceiling roses, &c. Many of these fittings have already been described in our columns, and are well known to the electrical trade. Mr. Lundberg has given a good deal of attention to high voltage fittings, and has introduced some new patterns embodying high voltage requirements.

A list has been issued by Messrs. W. O. Rooper & Robins, electric light engineers, of 3, Newgate Street, Chester and Stafford, in which they give a list of electric lighting and power contracts carried out by them in various public works, country houses, business establishments, residential premises, &c., in the provinces.

Messrs. Schischkar & Co., of 67, Stafford Street, Birmingham, and Nottingham, who are sole agents for the L. W. Pond Machine Company, of America, send us an illustrated list of the English and American machinery and tools they have in stock in this country. The list shows lathes, drilling machines, chucks, also milling, emery grinding, and shaping machines, as well as various other engineers' tools.

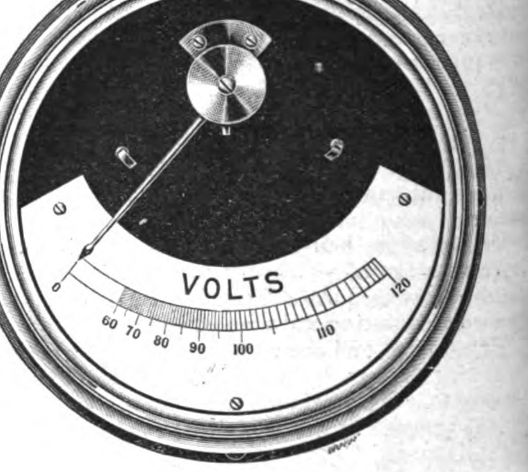
Change of Address.—Mr. S. Harrison, late of Ellesmere Works, Newtown, and 697, Ormskirk Road, Pemberton, near Wigan, announces that he has taken over new showrooms, offices and works, at 73, Wallgate, Wigan, where he will carry on business in electrical accessories, switchboards, incandescent lamps, arc lamps, fittings, &c. Mr. Harrison has been appointed sole agent for the North of England for the Crescent arc lamp and the Hard incandescent lamps. All letters should be sent to the new address.

Change of Name.—The business formerly carried on at Maritzburg by the Excelsior Electrical and General Engineering Company is now being conducted under the name of Messrs. Brady and Wyles, electrical engineers, at 192, Church Street, Maritzburg. The firm has recently carried out some important electrical contracts in that city, including three private plants—one for the Government Laboratory at Allerton, and two other Government contracts.

Coke v. Richardson.—In the Westminster County Court on Tuesday his Honour Judge Lumley-Smith, Q.C., tried the case of Coke *v.* Richardson, which was a claim for £20 odd for work done by a gasfitter and plumber of Whitcombe Street, W., against the defendant, an electrical engineer, of Southport. Evidence was given that defendant was fitting an electrical installation at the Clarence Hotel, Charing Cross, and a gas engine was to be used. Other work was required, and plaintiff did it. The defence was that part of the work had been done upon the order of Mr. Buxton, the owner of the hotel, and that plaintiff had rendered an account to him, and that all that was due to the plaintiff had been paid to him. His Honour found that the question of the work was really between Buxton and Richardson, and that the latter was liable to the plaintiff. There would be judgment for the plaintiff for the amount claimed with costs.

Commutator Bars.—The Forest City Electric Company, of Cleveland, O., has issued an 1898 railway catalogue of roll drop and drop forged commutator bars. The list contains details of bars for Westinghouse, General Electric, Edison, Walker, and other railway motors.

McWhirter's Patent Shielded Instruments.—It is interesting to notice the tendency among instrument makers and users to revert to the permanent magnet in the manufacture of ammeters and voltmeters and other electrical measuring instruments. The causes underlying this change are twofold: Firstly, there is no doubt that the production of finely made instruments constructed on the D'Arsonval principle has tended to bring permanent magnets into favour, not because they are any better or more reliable than they were 10 years ago, but because instruments of this class possess so many good qualities that the main objection, viz., the unreliability of the test of magnets, has been lost sight of, and on all hands we hear of engineers using such instruments as standards, regardless of the fact that they are only fit for secondary standards. As such, instruments of the D'Arsonval type are admirable, but it should never be forgotten that occasional comparison with an absolute standard is essential. The second, and, perhaps, the main reason for this reversion is the failure of electro-magnetic instruments to meet the demands of electrical engineers. The need for accurate measuring instruments is ever increasing, and electro-magnetic instruments, in spite of the paramount advantage of permanence, fail in many respects to meet this great want. The engineer expects his instruments to give accurate results under all conditions of temperature and in stray magnetic fields of great and ever-varying strength, and as the field of the average electro-magnetic instrument is comparatively weak, the stray field due to leads carrying, say, 200 amperes and upwards has a very substantial effect; also, in cases where the switchboard has to be close to the dynamo, there may also be a very serious disturbance. In some cases these troubles can be avoided by careful design, but in most cases this is impossible. The instruments which are described below lead us to hope that the electro-magnetic instrument is beginning to move faster towards perfection than it has been doing lately, for in them some of the most serious drawbacks to their class are either removed or greatly reduced in importance. Mr. McWhirter's invention is very simple, and consists in the substitution of an ironclad bobbin for the ordinary brass one. This modification, although so simple, has, as Prof. Jamieson has shown in his report, a very marked effect on the working qualities of the instrument, especially in the matter of freedom from the disturbing effect of stray magnetic fields. There have been several screened instruments produced, the most general plan being to make the outside case of iron. The evil of this plan is that the outer case, being



irregular in shape and thickness, and having of necessity an opening through which the scale can be read, becomes polarised, and thus the screen itself becomes a source of the very disturbance it was designed to guard against. In the case of Mr. McWhirter's screen, the iron case is placed on the coil only, and, moreover, forms a part of the magnetic circuit; being of even thickness and symmetrical shape, it is not at all liable to polarisation, and as the outer iron coat is ½-inch thick, the shielding is almost perfect, as shown in the tests. It may be thought that such a mass of iron would produce a great increase in the error due to residual magnetism; but this is not so, as the tests show the error is no greater than in the case of the ordinary instrument with which it was compared, and more recent instruments give results considerably better than this. The ironclad coil possesses other advantages, chief among which is the great reduction in the power necessary to work the instruments. The power used in a McWhirter voltmeter is only one half of that necessary to work a corresponding voltmeter with an ordinary coil, and it is thus possible to wind the coils either entirely of manganin, or with a much larger proportion of this alloy than is possible when a greater number of watts are necessary, consequently the errors due to internal heating and to changes in atmospheric temperature are reduced to an insignificant amount. Tests have been carried out by Prof. Jamieson, which show clearly the advantages obtained by adopting the McWhirter coil in the manufacture of electrical measuring instruments. Comparisons of the resistance when hot, after a 20 hours' run (5,112 ohms), with the resistance when cold (5,082·5 ohms) showed the error due to this cause to be very slight, amounting in all to only ·58 per cent. While the voltmeters were indicating approximately 100 volts, a horse-shoe magnet was placed so as to produce a maximum deflection of the pointer, which was noted; the poles of the magnet were then reversed, and the deflection in the opposite direction noted. The mean of the two readings was taken as the percentage error due to the external magnetic field.

The McWhirter voltmeter gave an error of...	0·75 per cent.
The ordinary voltmeter	6·00 „
A new engine room volt gauge	5·00 „

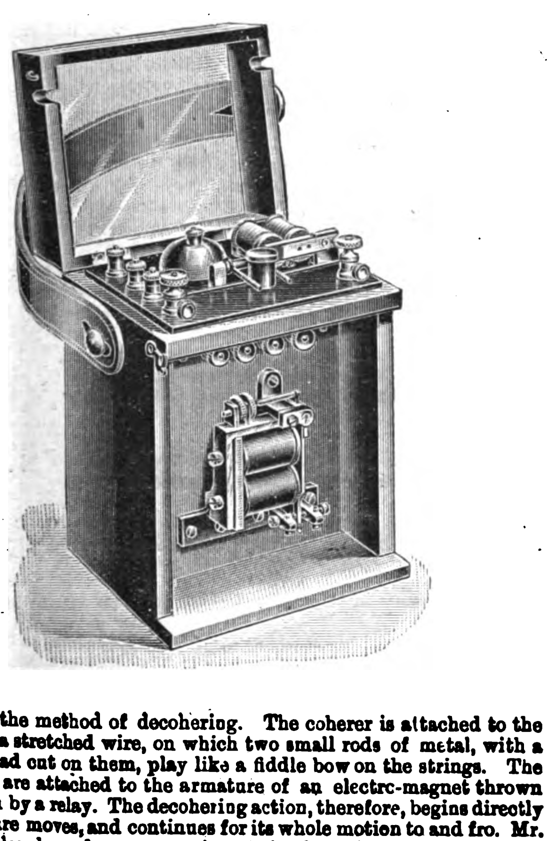
Prof. Jamieson summarises the tests as follows:—"I have to report that your newly patented shielded voltmeter is less affected by external magnetism than any other electro-magnetic one which I have seen. The temperature is also negligible, being only ⅓rd of 1 per cent., at 100 volts, after 20 hours in circuit." The General Electric Company, Limited, of Queen Victoria Street, London, and Peel Works, Manchester, are the sole licensees and makers of these improved shielded instruments.

The National Telephone Company v. Atkinson and Day.—In the Queen's Bench Division on Tuesday, before Mr. Justice Day, the case of the National Telephone Company *v* Atkinson and Day came on for hearing. Counsel's statement disclosed a curious state of facts. The action was brought to restrain the defendants from cutting, or otherwise interfering with, the plaintiffs' wires. It appeared from counsel's statement that the first defendant, Atkinson, was a tailor, carrying on business in the Fulham Road, and for a number of years telephone wires had been carried above his premises. In October of last year he had a conversation with the second defendant, Day, who asked him why he did not get a rent from the telephone company for allowing the wires to be carried over his house. Day suggested 2s. 6d. per annum per wire as rental, and stipulated that if he received this sum he was to have 25 per cent. of the proceeds. Atkinson agreed to this, and Day accordingly wrote to the company. They not replying he wrote again, threatening to cut the wires, a threat which, it afterwards transpired, was made wholly without Atkinson's authority, and, in fact, against his wish. In face of this threat the telephone company came to the court and obtained an interim injunction. It was then suggested that the motion should be treated as the trial of the action, and the plaintiffs agreed to this course provided that Day, who was in the wrong, paid the costs incurred. This he would not do, so the action went on. Counsel for the plaintiffs called Mr. Atkinson the first defendant, who bore out the opening facts, and said he never authorised Day to threaten to cut the wires. The wires had been over his house for 10 years, and he had never suffered any inconvenience therefrom. Mr. Day gave evidence on his own behalf, stating that he did not care about the injunction, as Mr. Atkinson had withdrawn his authority, he could not possibly do anything. The only thing he objected to was paying the costs. The injunction, so far as he was concerned, was not worth waste paper. Mr. Justice Day said he did not see how Atkinson could proceed with his claims to get a rental unless he had been prepared to cut the wires. The best conclusion he could come to, was to find for the plaintiffs, without costs.

Personal.—It is stated in an Aberdeen paper that Mr. W. McWhirter, M.I.E.E., of Aberdeen, is sailing for India on 25th inst., to carry out a new system of electrical train signalling. He will afterwards proceed to Cape Town on the same business. During his absence his electrical engineering business in Glasgow will be carried on by his son, Mr. Anthony C. McWhirter, A.I E.E.

Pritchetts & Gold.—This firm ask us to state that in future all their correspondence in connection with the manufacture of storage batteries will be conducted from their works at Feltham, Middlesex, to which address all communications relating to that portion of the business should be forwarded.

Receiver for Wireless Telegraphy.—We illustrate below a new receiver for wireless telegraphy, which is being made by Messrs. Miller & Woods, of 2, Gray's Inn Road, W.C. This, we understand, has been provisionally protected by Mr. L. Miller. The chief



novelty is the method of decohering. The coherer is attached to the middle of a stretched wire, on which two small rods of metal, with a screw thread cut on them, play like a fiddle bow on the strings. The small rods are attached to the armature of an electro-magnet thrown into action by a relay. The decohering action, therefore, begins directly the armature moves, and continues for its whole motion to and fro. Mr. Leslie Miller showed some experiments in signalling without wires at the Institution of Junior Engineers' conversazione last Saturday, and on that occasion no shunts whatever were used to prevent the spark of the relay influencing the coherer, but the bell only gave single rings. The coherer used consisted of an ebonite cup, in the inside of which there were some nickel filings bridging over a ⅛th-inch gap between the ends of the stretched nickel wire. The method of decohering can, however, be applied to the Marconi coherer, or most other forms. The apparatus shown is intended for lecture purposes. For working over long distances a more sensitive relay is required than that shown in the illustration.

Utilisation of Water Power in Italy.—It is reported that Messrs. Ganz & Co, of Buda-Pesth, have acquired the rights to utilise the water power of the river Tanaro, in the province of Piemont, and plant is to be put down to generate and distribute electrical energy for lighting and power purposes in the neighbourhood. It is stated that 2,000 H.P. is available.

ELECTRIC LIGHTING NOTES.

Aberdeen.—The Town Council has sent back to Committee the proposal to charge 6d. for the first hour daily of the maximum demand for current for power purposes, and 1½d. per unit after. At the last meeting, the electric lighting accounts for the year 1897 were submitted by Councillor Johnston, who said that since the new system of charging had been adopted, a good many complaints had been received from consumers who formerly paid 5d. on the first hour's consumption, and were now charged 6d. The system, which had been adopted by other corporations, was introduced last year. He did not wish to characterise the class of consumers from which the complaints came as the consumers, but they did not pay the department so well as those who came within the scope of the rule as to the rebate; and the committee had acted in as equitable a manner as they could. During the past six months they had had a rather heavy expenditure through changing the system. The engineer informed him that during the past half year there had been something like £300 spent in connection with the change of system, which would not occur again for a considerable time. Had it not been for that they would have had a good balance.

Barton-on-Humber.—The following from the *Leeds Mercury* of the 10th inst. will interest electrical firms:—"Wanted, electric light installation at Barton-on-Humber. This is a thriving manufacturing town of considerable importance, at present inadequately served by a small private gas company with exorbitant charges. A local syndicate is prepared to render considerable financial aid, and would also give other assistance which would be of value to the promoters of such a scheme. Address C, 190, Mercury Office, Leeds."

Barking.—The Board of Trade has written to the District Council inquiring whether the undertakers of the electric lighting order proposed to connect the intermediate conductor of their three-wire system of mains with earth. The Board pointed out that the concurrence of the Postmaster-General was necessary for an earth connection.

Belfast.—The engineer recently reported that machinery and boilers for the new electric station were being delivered and placed in position, and he hoped to have the first section of the establishment in working order shortly.

Blockley.—A copy of an order served on Mr. H. N. Warburton, owner of the electric lighting installation at Blockley, has been received by the Parish Council from the Board of Trade, together with the regulations as to the installation.

Bradford.—The Mayor submitted the gas and electricity accounts for the half-year at the last Council meeting. Regarding the electricity department he said that the total income for the half-year ended December 31st, 1897, was £10,842 0s. 7d., as compared with £9,570 13s. 2½d. in the corresponding period in the previous year, or an increased income of £1,271 7s. 4½d. The total expenditure for the half-year, which included interest and sinking fund, was £7,942 18s. 8d, against £5,570 4s. 1d. for the corresponding period. The profit for the half-year was therefore £2,699 1s. 11d., as against £4,000 9s. 1½d. for the similar period of 1896. The decrease in profits of £1,101 7s. 2½d. as compared with the corresponding period, was explained chiefly by the increased interest and sinking fund charges, amounting to £885 extra, together with sundry items of repairs to machinery, including renewal batteries, &c. The number of consumers was at present 640, as against 470, or an increase upon the corresponding half-year of 36 per cent. The total number of units consumed was 550,300, against 477,342, or an increase of 15¼ per cent. The total profits since the opening of these works, in September, 1889, to December, 1897, after paying interest and sinking fund, amounted to £16,733 0s. 6d., and the total amount written off for depreciation had been £7,307 15s. 6d., leaving the sum of £9,425 5s. to be appropriated as the Council might direct. The trade profit, *i.e.*, the profit before charging interest and sinking fund, was £4 11s. 9½d. per cent. for the half-year on the capital outlay. The net profit, *i.e.*, after charging interest, sinking fund and depreciation, showed £1 2s. 7d. per cent. for the half-year. Taking the December and June half-years together, the trade profit was £11,234 10s. 1d., representing £8 3s. 3d. per cent. per annum on the capital outlay. He thought this was a reasonable report, and that the Council had reason to be satisfied with the working of the department.

Brewery Lighting.—Messrs. Polkinghorne & Co.'s new brewery at Mutley is to be lighted electrically, and Messrs. Lord and Snand are putting down a Taunton dynamo for supplying 260 8-C.P. lamps.

Brighton.—The Town Council on Monday decided to reduce the price of electricity from 1½d. per unit after the first hour to 1d. The change, it is stated, will not take place for three months. The lamps in Dorset Gardens, are in future to be lighted by electricity instead of gas.

Bristol.—The Electrical Committee decided on Friday last to reduce the charges for electric current for power purposes, subject to a special agreement being entered into, from £6 per annum per kilo. installed, to £5 per annum per kilo. demanded where the customer has no private plant on his premises, and £5 per annum per kilo. installed where the customer has a private plant. It was also decided to reduce the charge for electricity consumed for motive power from 2d. to 1½d. per unit, subject to a sliding scale of discounts varying from 2 to 15 per cent. The Local Government Board has sanctioned the borrowing of £23,000 for public electric lighting. Mains are to be extended in various thoroughfares.

Buenos Ayres.—On February 12th the tenders for the public lighting of the City of Buenos Ayres were opened. A tender for electric light was presented by the City of Buenos Ayres Electric Light Company, and for gas by the New Gas Company, and the River Plate Gas Company. These tenders are, says the *Review of the River Plate*, more or less the same as those presented on a previous occasion, and it is possible that they will not be accepted. The Municipality evidently desires to get the public lighting done for nothing, and our contemporary recommends the authorities, if they desire to receive tenders that will benefit the city, to pay their gas and electric light bills when they fall due. Cash payments will soon bring about cheap gas and electricity.

Burton-on-Trent.—At the last meeting of the Council, Alderman Lowe said with reference to the defects in their electric lighting service, they had had Mr. Bailey (the engineer of the Metropolitan Electric Lighting Company) down from London, and he had made an exhaustive inspection of their appliances, but up to the present his report had not been received.

Buxton.—Prof. Kennedy has been instructed to prepare plans and specifications, and obtain tenders, for a municipal installation. The cost of the plant necessary for 6,000 8-C.P. lamps, and the necessary trunk and distributing mains—will be £12,500; buildings, £3,000; meters and house service £300.

Carlisle.—The Council has accepted the tender of Mr. John Laing, Carlisle, for the erection of the electric light station for £7,668.

Cheltenham.—The electrical engineer's report for February shows the total number of services connected was 241, with an equivalent of 14,600 8-C.P. lamps. He is reporting as to the means of improving the lighting of certain roads by arc lamps. The secretary of the Ladies' College recently complained of the large increase in the account for electric supply to St. Hilda's for the last quarter, amounting to £40 odd for 2,027 units, whereas for the corresponding quarter last year the account was £28 odd for 1,195 units, although the number of lamps in use was the same. The electrical engineer having inquired into the matter, reports that he has tested the meters, and in his opinion the principal reason for the large increase was the lavish use of the lamps and want of care in switching them off when not required. The gas manager does not consider the incandescent gas burner is yet in a satisfactory condition for street lighting.

Country House Lighting.—Kedleston, Lord Scarsdale's house near Derby, is to have the electric light. There will be a steam plant, with "D.P." accumulators, and about 250 lights fixed at present. The work has been entrusted to Messrs. Drake & Gorham.

Crickhowell.—The Parish Council is to consider whether to go in for electric lighting or to construct new gas works.

Crieff.—A report was recently furnished to the Town Council by Mr. R. F. Yorke, as to forming a company for providing electric light for the town—the motive power for which is proposed to be supplied by the Falls of Turret, some three miles north-west of the town. Mr. Yorke says that the available head is from 500 feet to 600 feet.

Darfield.—The District Council last week decided to apply for an electric lighting provisional order.

Fareham.—The District Council has decided to apply for power to borrow £2,900 for the purpose of adding to the electric light plant. It was pointed out that the proposed expenditure would provide a second plant for use in case of breakdown, and also for any increase in the demand for the light.

Glasgow.—The Electricity Committee recommends the expenditure of about £20,000 on dynamos and engines, lead-covered cables, &c., required for the new electric lighting station at Port Dundas, and for the more complete equipment of the existing station.

West Nile Street is to be lighted with electricity by means of lamps suspended from the trolley poles.

Glossop.—At the last Town Council meeting, the Town Clerk said he had received applications from three consulting engineers regarding the electric light scheme. The applications were referred to a sub-committee.

Greenock.—Mr. Teague's electric lighting scheme, which includes lighting the principal streets by means of 40 2,000-C.P. arc lamps, also the lighting of the James Watt Dock, was before the Corporation last week. The estimate is £27,500, exclusive of cost of site. The estimated revenue is about £3,300, and the expenditure:—interest on capital, £750; management expenses, £1,650; depreciation, £900. A Corporation site in Hunter Place has been selected. The Corporation adopted the scheme.

Hackney.—The Vestry has received letters from several electrical firms in reference to the electric lighting scheme, but only those schemes will be considered which were received in accordance with the published advertisement. Mr. A. T. Snell has offered his services in connection with the scheme, and his letter is before the Electric Lighting Committee.

Hampstead.—The question of electric lighting for the new workhouse buildings is in the hands of the Works' Committee.

Japan.—Of the 42 largest cities in Japan, from Tokio, with 1,368,000 population, down to those of 26,000, electric lighting systems are installed, says *Daily Tenders and Contracts*, in 24 only.

Leeds.—The *Yorkshire Daily Post* says that the Yorkshire House-to-House Electric Supply Company has refused the price offered by the Parliamentary Committee of the Leeds Corporation for its undertaking. The proposal was to give the company £210 2½ per cent. Redeemable Leeds Corporation Stock for every £100 which may have been properly expended on capital account. In view of this refusal it is understood that the Corporation will proceed with their provisional order, by which they seek power to issue 5 per cent. Irredeemable Stock.

London.—The St. George's Vestry has received a letter from the Board of Trade, stating that as the Brush Electric Lighting Company had elected to proceed with the works authorised by their provisional order of 1892, the Board did not see its way clear to sanction a provisional order, under which the Vestry can supply electrical energy. The Vestry resolved to refer the matter to the Electric Light and Dust Destructor Committee to consider the best method of approaching the Board of Trade again in relation to the subject.

Lowestoft.—In connection with the proposed combined electric lighting and destructor scheme, Mr. Hawtayne and the surveyor are to prepare a plan showing the position of the destructor. The Horsfall Furnace Syndicate is to submit drawings, estimate, &c., of a 4-cell Horsfall destructor and plant for clinker grinding.

Lynn.—The Electric Lighting Committee has received Prof. Robinson's report on electric lighting, and the Council will consider it in committee. There is to be opposition.

Maidenhead.—The Electric Lighting Committee is to engage a consulting engineer to prepare a scheme and report at a fee of 75 guineas.

Maidstone.—The Electric Lighting Committee has recommended the Council to consult Mr. Hawtayne, or some other expert, as to the best method of carrying out the provisional order.

Marylebone.—The Vestry last week resolved to proceed with the execution of the proposed electric lighting works as soon as possible after the grant of the necessary powers which are now being applied for.

Morecambe.—A Local Government Board inquiry was held on 9th inst. *re* application for a loan for £10,000 for the extension of the electric lighting works. The Clerk explained that with reference to the recent arbitration case with the old electric light company, the Council had been awarded as their share £1,179.

Newcastle.—At the last City Council meeting, when the question of street lighting arose, it was stated that the electric light companies had replied to inquiries that the price for the street lamps would be reduced if more lamps were used. It was further stated that the City Council pays £42 a year for each lamp, but if they had a larger number they could get them for £28 each. It was considered that if the Corporation put down municipal works they could have them for £14 each.

North Berwick.—The Town Council has appointed a committee to obtain information *re* electric lighting.

Perth.—The Sandeman Public Library is to be wired for electric lighting, but in the meantime no generating plant is to be put down.

Prestwich.—The District Council is to apply for a provisional order.

Sheffield.—The Sheffield Electric Light Company has given notice that after the end of the present month another 1d. will be taken off the price of the current, making it 4d. per Board of Trade unit.

The Corporation's common seal has been affixed to the agreement between the Electric Light Company and the Corporation respecting the transfer of the undertaking.

Spain.—A central station has just been completed and put in operation at Jadraque. Water power is utilised.

Sunderland.—A report has been submitted to the Electric Lighting Committee by the electrical engineer, showing that owing to the increasing demand, the station was becoming incapable of supplying all requirements. The present capacity was 745 electrical H.P. The committee will recommend the Council to apply to the Local Government Board for powers for further extensions. The amount asked for steam dynamos, switchboards, &c., will be £12,728; for the extension of feeders and mains to the Workhouse if required, £12,540; making a total of something like £26,000. It was decided to ask the Council for leave to borrow £10,000 for immediate requirements.

Taunton.—The new connections during February were equivalent to 512 8-C.P. lamps. The Mayor recently stated that whereas the expenses of the undertaking had only increased by £178 during the year, the profit realised had increased by £271 8s. 4d., and after paying all expenses they had a balance on the year's working of £43.

Torquay.—The Corporation electricity works were inaugurated yesterday afternoon.

Wallingford.—The Guardians have abandoned the idea of using electric light for the Workhouse. The annual cost (200 lights) of electric light was put at £264 16s., gas £199 4s., oil £165. Gas is to be used.

Walsall.—At the Town Council meeting on Monday, the Electric Lighting Committee reported that the number of consumers at the end of February was 104. They regretted to report that after paying interest on loans and providing sinking fund there was a deficiency of £531 17s. 7d. This, with the loss of £445 3s. 10d. on the previous year's working, made the total deficiency of the undertaking up to December 31st last £977 1s. 5d., and with a view to meeting the same the Finance Committee had been requested to include in the next rate estimate the sum of £400 in respect thereof. The report was adopted.

Wednesbury.—The Mayor was calling a special Council meeting for Wednesday last, to consider the question of providing electricity for the town.

West Ham.—The tenders for the wiring of public buildings for the electric light have been referred to the electrical engineer to report upon.

Weston-Super-Mare. — Messrs. Foote & Milne, of Victoria Street, London, have written to the District Council suggesting that they should transfer their electric lighting provisional order. The letter will lie on the table as the Council are intending carrying their order into effect.

Willesden.—The Electric Light Committee, after considering the report of the sub-committee appointed to inspect various electric lighting stations, has recommended that steps be taken to secure the services of an electrical engineer. The appointment will not take place until the new Council is elected.

Winchester.—It is expected that the electric lighting station will be completed in two or three month's time. The laying of mains has been commenced.

Withington.—The desirability of arranging terms with the Manchester Corporation for the supply of electric light to Withington, was considered by the District Council last week, and was to come up again at a special meeting to be held yesterday.

Woking.—The Surveyor reports that the Electric Light Company has promised to replace the old lamps in the streets with new.

Yarmouth.—Mr. A. W. Ranken, the Corporation electrical engineer has given in his resignation to take effect on May 31st. The Electric Light Committee has expressed appreciation of Mr. Ranken's valuable services. It is proposed to adopt the following scale of charges for electric motors: Per 1 horse-power motor, up to 100 units per quarter, 3½d. per unit; 100 units to 300 units, 3d.; 300 units to 500 units, 2½d.; over 500 units, 2d. Other size motors in proportion.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Aberdeen.—The Corporation Tramways Bill is being opposed by the House Proprietors' Association.

Alexandra Palace Electric Railway.—The new electric railway at the Alexandra Palace, arrangements for which have been progressing during the past three months, is now taking a practical form under the supervision of the consulting engineers, Messrs. Taylor & Field. The work is being carried out by the Imperial Electric and Power Company, who are working in conjunction with Messrs. Wandruszka & Co., of Berlin. The estimate of this, which was originally to be £6,000, has had to be materially increased to have a double line of rail, and the cost now will reach nearly £10,000. It is intended to run the electric cars with the overhead trolley system. Each car will seat 60 people, and will be about 40 feet long. They are *facsimiles* of the American pavilion car, and will be fitted with 70 horse-power motors. The fare will be 1d., either up or down the hill. This will be a great convenience to all visitors to the Palace travelling by the Great Northern Railway, the North London Railway, the South-Eastern Railway, and the London, Chatham and Dover Railway to Wood Green station, as well as to visitors going to the Palace Gate station on the Great Eastern, and, in fact, the whole of that enormous district including Hornsey, Wood Green and Tottenham.

Brighton "Underground."—In consequence of strong opposition on the part of the Brighton Corporation and other local interests, the Brighton Underground Railway Bill has been removed from the list of Bills which has been referred for consideration to the Committee of the House of Lords. The scheme has been referred to in these columns on several occasions.

Calcutta.—The directors of the Calcutta Tramways Company have laid before the Calcutta Corporations a lengthy communication dealing with their proposals in regard to electric traction.

Coventry.—The Stoke Parish Council has approved of the positions of the trolley poles of the Coventry electric tramways.

Dublin.—The Clontarf section of the electric tramways, which we have already described, was to be opened this week.

Electric Power Distribution.—A third time the Wolverhampton Town Council, at their monthly meeting on Monday, decided not to admit the Midland Electric Corporation Power Distribution, Limited, into the borough. At the meeting in question a letter was read from the Board of Trade regarding the provisional order sought by the Electric Corporation. The Town Council had refused to grant their permission to the company to enter Wolverhampton, and the company now asked that the consent might be dispensed with. The applicants, in their communication to the Board of Trade, submitted that the Corporations of Wolverhampton and Walsall and the Tipton District Council were not entitled to withhold their consent unreasonably, and that in this case they were doing so. Subsequently Councillor Leir Johnson moved that the Council rescind their previous resolution, and assent to the promotion of the provisional order. Alderman Jackson seconded the resolution, but after considerable discussion it was rejected.

Mr. J. F. Albright (chairman), Mr. G. L. Addenbrooke (engineer), and Mr. A. L. Lowe (secretary), of the Midland Electric Corporation for Power Distribution, Limited, were present last week at a special meeting of the Wednesbury Town Council held to discuss the scheme. It was resolved to consider the whole question at another special meeting of the Council in Committee. This was done on Monday evening, when, after a long discussion, it was decided that the Council should apply for a provisional order themselves in order to have the power of supplying electricity in their own hands.

On Monday, at the meeting of the Walsall Town Council, the Electric Lighting Committee reported that the Board of Trade had asked the Corporation to state their reasons why the Board should not dispense with the consent of the Corporation to the application by the Midland Electric Corporation for Power Distribution, Limited, and the town clerk has replied that the Council strongly object to the proposal of the company to supply electricity within the borough. The report of the Committee was adopted on the proposition of Councillor Brownhill.

The Tipton District Council has resolved to withdraw its opposition to the scheme provided the company will supply electricity for lighting in bulk to the Council at 2d. per unit, this to include the supply of mains.

Folkestone.—The Sandgate District Council has been informed that the Folkestone Electric Tramways Bill will not be proceeded with during the present session.

Hartlepool.—On Tuesday last week one of the guard wires broke in Northgate, but no one was injured.

Hastings.—Last week the Council, meeting in committee, passed resolutions favouring the placing of trams in the principal thoroughfares, excluding the Front Line and Robertson Street. The borough engineer is to bring up a report as to cost, line of route, and other details, and the Council will then probably apply for powers under the Light Railways Act.

Hendon and Finchley Light Electric Railway.—On Saturday last, at the Hampstead Vestry Hall, Mr. Fitzgerald and Colonel Boughey, Light Railway Commissioners, resumed an inquiry, opened on Friday at Hendon, into the scheme of the Hendon and Finchley Districts Light Railways Company. Mr. Vesey Knox, M.P., for the promoters, at the outset said that the line would serve what was practically a remote agricultural district, though within seven miles of Charing Cross. The line, which would be worked by electric traction with overhead wires, would start at Canfield Gardens, Hampstead, opposite the Metropolitan Railway station, following the main road to Church End, Finchley, while another ran through Hendon to the Hendon station of the Midland Railway. It was seven miles three furlongs long, a little over a mile of this being in the parish of Hampstead and County of London, seven furlongs in the parish of Finchley, and the rest in Hendon. Many of the people who lived in that part of this district, which was within six miles of Charing Cross, were two miles from the nearest railway stations. The service from Finchley to Hampstead would be one car in 15 minutes, and from Hendon one in 10, making a service of one car in six minutes through Hampstead. Evidence in support of the scheme was given by Sir Douglas Fox and Mr. Wragg, the engineers, Mr. J. T. Firbank, M.P., and Mr. W. M. Murphy, the promoters, Mr. Hearne, chairman of the Hendon District Council, and others. There was opposition from the Hampstead Vestry, the L.C.C., and the Middlesex County Council. The inquiry was adjourned.

Leith.—It is stated that a hitch has occurred in connection with the purchase of the tramway undertaking in Leith. The lessees are described in the draft lease as Messrs. Dick, Kerr & Co., and the Edinburgh and District Tramway Company. It has been discovered that the Edinburgh and District Tramway Company are not licensed lessees, not having got sanction from the Board of Trade. Until this matter is rectified, negotiations for the purchase in Leith will be practically at a standstill.

Norwich.—In the House of Commons on Monday night the Norwich Electric Tramways Bill was read a second time and committed.

Orme's Head.—The Llandudno Council, and the promoters of the Orme's Head Tramway, have agreed upon terms whereby the Council shall have the option of purchase in 28 years, on a return at the rate of 4½ per cent. on total capital invested in the undertaking.

Paisley.—The Paisley Tramways Company recently entered into an agreement with the British Electric Traction Company for taking over the tramways and working them electrically. The British Electric Traction Company has now laid a comprehensive proposal before the Town Council regarding the scheme. Conditional on the Council granting the company a lease of the streets of the burgh for a period of 28 years, it will undertake to put down and work an overhead trolley system, to extend from Paisley Cross westward to Johnstone, southward to Potterhill, northward to Renfrew, and eastward to join with the outlying extremity of the Glasgow tramways. A Committee of the Council has instructed Mr. Teague, electrical engineer to the Corporation, to make inquiries at towns which have adopted the trolley system, and report to the Council in committee. Should the Town Council accede to the agreement, Parliamentary sanction would require to be obtained, and power will be asked to acquire property in narrow streets through which the tramways may run.

The Proposed City and Brixton Electric Railway.—The engineers have prepared, for the information of Parliament, detailed estimates of the cost of carrying out this scheme. The proposed line, which will run from a junction with the City and South London Railway, under the High Street, Borough, to Brixton Hill, is estimated to cost in the aggregate £818,040, of which the railway will cost £786,415, the cost of widening the City and South London Railway, in order to accommodate the traffic, £24,725, and the proposed subway to the Oval station of the City and South London Railway £6,900. The line will be three miles five furlongs in length, and will be constructed in every respect similar to the City and South London Railway, which it is proposed to purchase from the point where the new line will join it to its termination in King William Street. The capital of the company is proposed, says the *Financial Press*, to be fixed at £1,200,000, with the right to raise a further £400,000 by the issue of debenture stock. The engineers will be Sir Benjamin Baker, Mr. David Hay, and Mr. B. Mott. It is stated that the prospectus of this company will shortly be before the public under the title of the City and Brixton Electric Railway Company.

Yarmouth.—The solicitors to the Yarmouth and Gorleston Tramways Company have written to the Town Council as follows:—"Under the Yarmouth and Gorleston Tramways Extension Provisional Order Confirmation Act, 1897, the company, as you are aware, are empowered to construct the extension of their line thereby authorised, and to work the entire traffic by electrical power. With a view to give the greatly improved service which this modern method of traction would permit, the company are prepared to carry out the powers of the Act at an early date; but as there does not appear at present any probability of the necessary current supplied by the Council on the west side of the river, it seems that the company themselves will have to provide it, and in that case the company would be willing to erect a generating station, capable of supplying not only the requisite power for working their tramway, but, also to provide current for lighting purposes on that side of the river, should the Council desire them to do so, on terms to be agreed." The company proposes to employ the overhead trolley, and suggests a meeting with the Council to explain the proposals fully. The Electric Light Committee has asked the Company to submit written particulars of the proposals.

TELEGRAPH AND TELEPHONE NOTES.

The African Trans-Continental Telegraphs. — A Reuter despatch says that the *British Central Africa Gazette* reports that telegraphic communication between Zomba and Kota Kota was opened on December 10th. The actual construction of the line is now 60 miles north of Kota Kota, and holes have been dug 84 miles beyond that place. As Kota Kota was practically only opened up to European occupation on the death of the late Jumbe in 1894, it will be seen what great progress the country has made during the last three years. There is some idea of constructing a branch line from Kota Kota to Fort Alston. In view of the present troubles in northern Rhodesia, this would be of immense advantage. The telegraph staff at Blantyre has set up a telephone system there, and it is stated that a connection will shortly be made with Zomba. Towards the end of December there was an interruption on the telegraph line between Zomba and Fort Johnston. Mr. Kennedy, who went out to effect repairs, found that the breakdown was due to the fact that a native had built his hut directly under the wire, and when the hut accidently caught fire, the wire was softened and broke with the strain. The Acting Commissioner has now issued instructions to all the districts through which the line passes that natives should be advised not to build their huts within at least 10 yards of the telegraph track. The natives of Central Africa occasionally use the telegraph to send messages to each other in their own language.

Canada-Australia Proposed Cable.—In the House of Commons last Monday Mr. R. G. Webster asked the Secretary of State for the Colonies whether any further steps had been taken in regard to establishing a direct cable communication betwixt the Dominion of Canada and Australia, and if any papers would be laid upon the table on that subject. Mr. Chamberlain, in reply, said that the question was still under consideration, and no papers could then be laid.

Delays in Australian Telegrams.—In the Australian papers of last month, just to hand, we learn that on February 2nd, the following official message was received from Adelaide:—"Port Darwin line interrupted between Oodnadatta and Charlotte Waters. Line between Perth and Roebuck Bay working badly, and little prospect getting business that way." In consideration of the fact, which we have frequently pointed out, that there are only the two lines above referred to by which telegrams to Europe can be transmitted, the "prospect" of getting business through at all is none of the brightest.

Pacific Cable.—The Committee of the British Empire League, sitting at Ottawa on 11th inst., discussed the Pacific cable question, and a proposal was made for the creation of a trust under the authority of the several Governments concerned, with power to raise funds to establish and operate the line.

South American Cable Taxes.—According to the *Financial News* there seems to have been considerable discontent in the mercantile community in Brazil at the heavy tax which is placed by the Argentine Government on telegrams in transit from Brazil, *viâ* Buenos Ayres, to the west coast of South America. It has now been strongly urged upon the Brazilian Government that some retaliatory measures should be adopted, such as the placing of a heavy tax upon telegrams to or from the Argentine Republic. There is, of course, another way of meeting the difficulty—namely, the establishment of direct telegraphic communication across the continent from Rio de Janeiro to the west coast, without the detour through the Argentine Republic. But this is obviously an expensive expedient, and the other is being more strongly pressed upon the Brazilian Government.

The Telegraph Wire Export Trade.—February proved to be a fairly active month in the export trade of this country in telegraph wire and apparatus connected therewith. The exports for the month reached a total value of £75,276, as compared with only £37,929 in January last, and only £43,710 in the corresponding month of 1897. So far as the year has gone it shows a slight improvement over last year, but is still much below the activity recorded in the early months of 1896, the respective figures for the two months being, 1898, £113,205; 1897, £105,830, and 1896, £167,064.

The Telephone Service.—It is announced that at the annual meeting of the Association of Municipal Corporations to be held at the Guildhall on Saturday, 26th inst., the City Solicitor will move: "That it is undesirable that the jurisdiction of local authorities over telephone companies should be curtailed or interfered with by the undue exercise by Her Majesty's Postmaster-General of his rights or privileges under the Telegraph Acts; and that a representation to this effect be made to Her Majesty's Government."

The Portsmouth Chamber of Commerce is persuading its local Members of Parliament to support the movement in the House of Commons to upset the present arrangement between the National Company and the Post Office.

The London County Council has before it a report of the Highways Committee with reference to the National Telephone

Company's underground works. During last year the Council consented, subject to certain conditions, to the placing underground of the company's system in connection with 14 exchange stations. These conditions were to be embodied in an agreement, but the Highways Committee, having given careful consideration to the draft agreement, have come to the conclusion that additional conditions ought now to be inserted to provide—(1) that the company should pay a rent in consideration of its user of the public streets, and (2) that the present charges to subscribers should be reduced to amounts which in the opinion of the Council's engineer would, in the event of the Council establishing an independent telephone service for London, amply repay expenses and, as the system was extended, might possibly be reduced by 15 or 20 per cent. A draft agreement embodying these provisions has been submitted to the company, who in a letter to the Council have pointed out that, with reference to the first proposal, the company has to obtain the consent not only of the Council, but of the road authority, which latter may impose conditions, and that the company cannot be expected to make payments both to the Council and to the road authorities in respect of wayleaves under the streets, and, further, that such requirements are inconsistent with the demand for a cheaper telephone service. As regards the second proposal the company declines to discuss it, but is prepared to consent, as it has done in the case of some provincial towns and cities, not to increase the present tariff of charges. The Highways Committee think there is some force in the company's representation with reference to the possible effect of the first proposal, and they state they have reluctantly decided, should the Council approve, not to press for the clause to be inserted in the agreement. As regards the second point, they are of opinion that it is advisable in the interests of the inhabitants of London that the principle should be insisted upon. They will accordingly ask the Council to insist on the retention of this clause in the agreement. The schedule attached to the clause sets out the tariff proposed by the Council. The charges are to be—on a five years' agreement, for first connection £12 a year, second and additional connections £10, and private houses £8 a year; on a yearly agreement, first connection £15 a year, second and additional connections £12-£10, and private houses £10 a year. These tariffs are to apply to an area of 609 square miles, which comprises the towns of Dartford, Redhill, Croydon, Epsom, Richmond and Kingston on the south of the Thames; and Tilbury, Woodford, Romford, Epping, West Ham, Harrow, Ealing and Hampton Court on the north.

The Bootle Town Council will support the proposals of the New Mutual Telephone Company.

The Brierley Hill and Colwyn Bay District Council also support the company's proposals.

Western and Brazilian Telegraph.—*Money* says that some idea of a possibly impending arrangement between the Western and Brazilian Telegraph and the Direct West India Cable Company was mooted in the market last week, with the result that Western and Brazilian ordinary shares have been put up.

CONTRACTS OPEN AND CLOSED.

OPEN.

Belgium.—March 30th. Tenders are being invited by the municipal authorities of Ghent for the supply and erection, &c., of a complete installation for the electric lighting of the town dock. Particulars may be obtained from, and tenders to be sent to, l'Hotel de Ville, Ghent, Belgium.

Belgium.—April 1st. The Municipal Authorities of Seraing are inviting tenders for the concession for the supply of electrical energy in the town for public and private lighting purposes during a period of 30 years. Particulars may be had from, and tenders to be sent to, the College des Bourgmestre et Echevins, Seraing, Belgium.

Blackpool.—March 22nd. The Corporation wants tenders for a tubular boiler, superheaters, condensers, rectifiers, boosters, transformers, lead-covered cables, arc lamps and pillars. Borough electrical engineer, Mr. R. C. Quin. See our "Official Notices" February 25th.

Bournemouth.—The Corporation wants tenders for the electric lighting of the pier and pleasure grounds. Particulars *re* plant, &c., are given in our "Official Notices" this week. Borough engineer, Mr. F. W. Lacey.

Bournemouth.—April 4th. The Corporation wants tenders for motor vehicles for the collection of house refuse, &c. Borough engineer, Mr. F. W. Lacey. See our "Official Notices" this week.

Darwen.—March 28th. The Corporation wants tenders for the supply of steam engine and dynamos, piping, accumulators, switchboards, mains, arc lamps, pillars, &c. See our "Official Notices" March 11th.

Derby.—March 24th. The Corporation wants tenders for the electric wiring of the Lunatic Asylum and premises at Rowditch. See our "Official Notices" March 4th.

Derby.—April 12th. The Corporation wants tenders for the electric wiring of its Ford Street yard and premises. See our "Official Notices" this week.

Devizes.—March 21st. Tenders are wanted for the supply and delivery of two 40-kw. continuous current belt-driven dynamos for the Wilts County Asylum, Devizes. Engineers, Messrs. Massey & Allpress, 25, Queen Anne's Gate, Westminster. See our "Official Notices" March 4th.

Edinburgh.—March 22nd. The Council wants tenders for the additions and extensions to the electric lighting at the City Chambers. See our "Official Notices" March 11th, for particulars.

France.—March 30th. Tenders are being invited by the municipal authorities of Paris for the supply of the electrical conductors, required in connection with the electric lighting of the Square Vaugirard. Particulars may be had on application, and tenders to be sent, to l'Hotel de Ville, Paris.

France.—March 31st. Tenders are being invited by the Municipal Authorities of Saint Chamond (Loire) for the concession for the lighting of the public streets of the town, either by gas or electricity. Particulars from, and tenders to be sent to, La Mairie de Saint Chamond (Loire).

Hampstead.—March 31st. The Vestry wants tenders for the supply and erection of one or two steam alternators, switchboard panels, two induced draught wet back boilers, feed water heater, steam and exhaust pipes, feed pumps, 50 kw. exciter, and a feed water softener. See our "Official Notices" this week for full particulars.

Leyton.—April 4th. The District Council wants tenders for the supply of two dynamos, one transformer, two gas engines and connections, and switchboards for extension of the electricity works. Electrical engineer, Mr. H. C. Bishop. See our "Official Notices."

Plymouth.—March 23rd. The Corporation wants tenders for the supply of alternating current meters for the year ending March 31st, 1899. Particulars from Mr. J. H. Rider, Borough electrical engineer, East Street, Plymouth.

Spain.—March 21st. The Municipal Authorities of Santona (province of Santander) are inviting tenders for the concession for the electric lighting of the public streets of the town during a period of 20 years. Tenders to be sent to El Secretario del Ayuntamiento de Santona (Santander) from whence full particulars may be obtained.

Spain.—March 29th. Tenders are being invited by the municipal authorities of the town of Zafra (Badajoz province) for the concession for the electric lighting of the public streets during a period of 20 years. Particulars and conditions may be obtained from, and tenders to be sent to, El Secretario del Ayuntamiento de Zafra (Badajoz), Spain.

Switzerland.—April 30th. Plans and estimates are being invited, says the *Contract Recorder*, by the Government authorities of Fribourg, Switzerland, until April 30th next, for a projected electricity generating station to be established at Hauterine. Water-power is to be utilised, and the station will have a capacity of about 6,000 H.P. A premium of £120 will be awarded to the three schemes submitted which are considered to be the best. Plans and estimates are to be sent to the Department des Travaux Publics, Fribourg, Switzerland, from whence full particulars of the competition may be obtained.

The War Office.—April 27th. The Secretary of State for War is prepared to receive offers, competitive designs and specifications for the supply of portable electric search light apparatus. Particulars from the Director of Army Contracts, War Office, Pall Mall, S.W. See our "Official Notices" February 4th.

Victoria.—March 21st. The Telegraph Department of the Victorian Government Railways is inviting tenders for the supply of alternating current transformers and one main switchboard. Tenders to the Telegraph Superintendent's Office, Spencer Street, Melbourne.

Victoria.—June 24th. The Council of the city of Hawthorne (Colony of Victoria, Australia) is inviting tenders for the supply and erection of buildings, boilers, engines, dynamos, transformers, mains, meters, arc lamps, poles; also running the plant for three years. See our "Official Notices" March 11th.

CLOSED.

London, E.C.—The Court of Common Council has accepted the tender of Messrs. Ashwell and Nesbit for £145 9s. for installing the electric light in certain rooms in the Guildhall Library.

Newport.—The Council has accepted the tender of Messrs. W. T. Glover & Co. for £4,288 12s. 4d. for cables and underground work required for the extension of the electric lighting of the borough. The tender of the Electric Construction Company, Limited, at £661 for transformers, and that of Messrs. G. Smith and Co., Limited, Glasgow, for 30 arc lamps at £325 have also been accepted.

Portsmouth.—Mr. T. W. Quick's tender for the extension of the electric light station at £4,198 has been accepted by the Council. Other tenders have also been accepted for additional plant, including boilers, feed pumps, &c.

FORTHCOMING EVENTS.

1898.

Friday, March 18th.—State visit to the Northampton Institute for the purpose of inspecting it and formally declaring it open.

Saturday, March 19th.—E. E. Students' visit to the works of Messrs. Easton, Anderson and Goolden, Limited, Erith.

Monday, March 21st, at 8 p.m.—Society of Arts. Prof. W. Noel Hartley, F.R.S., on the "Thermo-Chemistry of the Bessemer Process," Lecture II. (Lecture III., March 28th.)

Yorkshire College Engineering Society. Annual general meeting.

Devizes electrical plant tenders. (Wilts County Asylum.)

Tuesday, March 22nd.—Blackpool Corporation electrical plant tenders.

Edinburgh electric lighting extensions tenders.

At 8 p.m.—The Institution of Civil Engineers (ordinary meeting). Further discussion on "Calcium Carbide and Acetylene," by Henry Fowler, Assoc.M.Inst.C.E.

Wednesday, March 23rd.—Plymouth Corporation electric meter tenders.

Thursday, March 24th, at 8 p.m.—The Institution of Electrical Engineers. "Cost of Generation and Distribution of Electrical Energy," by R. Hammond, member.

At 3 p.m. — Royal Institution. Prof. J. A. Fleming's fourth lecture, "Recent Researches in Magnetism and Dia-magnetism." (Lecture V., March 31st.)

Derby Asylum wiring tenders.

Friday, March 25th, at 8 p.m.—The Institution of Civil Engineers (students' meeting). "Internal Governor Friction," by H. O. Eurich, Stud.Inst.C.E.

At 5 p.m.—Physical Society at the rooms of the Chemical Society, Burlington House. (1) "On the Circulation of the Residual Gaseous Matter in a Crookes Tube," by Mr. A. A. Campbell Swinton. (2) "On some Improvements in the Roberts Austin Recording Pyrometer, and Notes on Thermo-electric Pyrometers," by Mr. A. Stansfield.

At 8 p.m.—Electro-Harmonic Society. Smoking Concert at St. James's Hall Restaurant.

Wednesday, March 30th, at 8 p.m.—Society of Arts. Prof. S. P. Thompson, on "Telegraphy Across Space." Mr. J. W. Swan, F.R.S., will preside.

Royal United Service Institution. Captain J. N. C. Kennedy on "Wireless Telegraphy."

NOTES.

Obituary.—Our readers will have heard with regret of the death of Sir Henry Bessemer, which occurred on Tuesday evening at his residence at Denmark Hill. Sir Henry was in his 86th year, he being born at Charlton, Hertfordshire, in 1813. His name will ever be remembered in connection with his process for the conversion of cast-iron into cheap steel, and the great difficulties he encountered in introducing his process are well-known matters of history. Wednesday's *Times* contains an interesting two-column notice of Sir Henry's life. The first recognition of Bessemer's work came from the Institution of Civil Engineers, in the shape of the gold Telford medal in 1859. In 1871—73 he was president of the Iron and Steel Institute, and founded a gold medal to be given annually for the most important improvement of the year in the manufacture of iron or steel. The Society of Arts awarded him the Albert gold medal in 1872, and in 1877 the Civil Engineers made him a member of their body, at the same time presenting him with the first Howard quinquennial prize. Two years later he became a Fellow of the Royal Society, and received the honour of knighthood, while in 1880 he was presented with the freedom of the City of London. From abroad he received many honours. He was offered the Grand Cross of the Legion of Honour, but, as permission to wear it was refused, he had to be content with a large gold medal given him by Napoleon III. He was an honorary member of the Iron and Steel Board of Sweden, a freeman of the City of Hamburg, an honorary member and gold medalist of the Society of Arts and Manufacturers of Berlin, and a Grand Cross of the Order of H.I.M. Francis Joseph of Austria. It will be remembered that Lady Bessemer died last year.

Mr. Main, a native of Aberdeen, whose untimely end we announced in our last issue, was best known to the electrical world as the inventor of the arc lamp known as the Fyfe-Main. This lamp he patented in 1881 in conjunction with Mr. A. L. Fyfe, and it appeared about the time when the early fever for electric lighting was at its height. A sum was offered for the patent which would have been a small fortune for the owners, but, unfortunately, a hitch occurred in the negotiations, the opportunity passed, and Mr. Main never received anything for his valuable invention, except the ordinary manufacturers' profits for the lamps he made in his own small workshop. For the 17 years preceding the invention of the Jablochkoff candle, the Serrin lamp was the only lamp capable of giving a decently steady arc light, but its mechanism was too complicated, and its working not quite steady enough for public lighting. Mr. Main unconsciously designed his lamp on the same general principles as the Serrin, but he immensely simplified the mechanism by lifting the feeding train bodily when the arc was made, and thereby doing away with the parallel motion in the Serrin. The Fyfe-Main lamp is in use for lighting the leading newspaper offices in London, including the *Daily Telegraph*, *Standard*, and *Daily News*, and also in the brilliant example of street lighting at Electric Avenue, Brixton. Anyone who has seen this lamp will admit that it is one of the steadiest and most reliable lamps in use. Mr. Main combined great inventive and mechanical skill with a sort of intuitive knowledge of the principles underlying his mechanical creations. He was the ideal man for the inventor with an idea and an insufficiency of mechanical skill to translate his idea into practice, and many well known men have owed much of their success to his valuable assistance. One of Mr. Main's recent patents is a revolving gas lamp for advertising and show purposes. The large glass case surrounding the gas jets is slowly revolved by the action of the heated air upon a light fan or turbine mounted in the frame above the gas jets. Simple as this problem may seem, it appears to have never been practically solved till Mr. Main, after much trial and many failures, made it a complete practical success. Mr. Main's estimate of his own abilities was too modest to allow him to advertise himself, but his sterling qualities were known and appreciated by his intimate friends.

The International Ohm.—The *Elektrotechnische Zeitschrift* states that in view of the impending publication of the Bill concerning electrical units of measurement, the German Imperial Post Office authorities have resolved to introduce the ohm in place of the Siemens unit. In future all new apparatus and measuring instruments will be standardised in ohms. Existing curved handled rheostats and resistances used in connection therewith will at once be regauged, whilst other apparatus and instruments will be similarly dealt with on being sent to the workshops for repairs as occasion may arise. Statements of resistances in official reports will in future always be expressed in ohms.

Mean Horizontal Candle-Power.—The mean horizontal candle-power of an incandescent lamp is usually taken as the measure of the light emitted. This, says New York *Electricity*, is perhaps the best measurement to take, but with certain of the new types of filaments will have to be replaced by the mean spherical candle-power. The mean horizontal candle-power can be obtained either by the laborious method of taking a large number of readings at different angles, or by spinning the lamp so as to obtain optically the mean candle-power. There have been doubts, though, on this spinning process as to whether it will give accurate results. Deformation of the filament, due to centrifugal force, would be the most likely cause of error, if any. Mr. C. P. Matthews contributes an article on this subject to a recent number of the *Physical Review*. His experiments were carried out at the Purdue University, and show conclusively that no such error exists. Thus the whirling lamp gave a mean horizontal candle-power of 9·649, while the figures obtained by plotting the series of readings for different angles and integrating the curve was 9·655 C.P. This shows an error of ·06 per cent. only, which is very well within the limits of photometric accuracy.

Electrical Energy (Generating Stations and Supply).—In the House of Commons on Thursday last week, the Earl of Morley moved:—"That it is desirable that a Select Committee be appointed to join with a committee of the House of Commons to consider and report—1. Whether, notwithstanding the provisions of Section 12 (1) of the Electric Lighting Act, 1882, powers should be given in any cases for acquiring land compulsorily for generating stations; and, if so, under what conditions as respects liability for nuisance, notices to surrounding owners, and otherwise. 2. Whether compulsory powers of acquiring land for generating stations, if proper to be given in any case, should be given where the proposed site is not within the area of supply. 3. Whether, in case of a generating station, however acquired, not being situate within the area of supply, power should be given for the breaking up of streets between the generating station and the boundary of the area of supply. 4. Whether powers should be given in any case for the supply of electrical energy over an area including districts of numerous local authorities, involving plant of exceptional dimensions and high voltage; and, if such powers may properly be given, whether any, and what, conditions should be imposed—(*a*) With respect to system and plant, and to the construction and location of generating stations, in view of the powers of purchase conferred upon local authorities by Sections 2 and 3 of the Electric Lighting Act, 1888; (*b*) with respect to the relations of the promoters to other undertakers, and to local authorities within parts of the area. 5. Under what conditions (if any) ought powers to be conferred upon promoters seeking to supply electrical energy to other undertakers and not directly to consumers." The motion was agreed to.

The House of Commons had the matter brought before it on Monday, and concurred in the House of Lords' resolution referring the question to a Joint Committee of both Houses. On Tuesday the House of Lords appointed the following peers to represent the House on the Joint Committee:—Lord Cross, Lord Spencer, Lord Knutsford and Lord Monkswell.

Engineers' Strike.—With reference to the statement in our last issue that the Employers' Federation had returned Messrs. Tangye's cheque for £500, Sir Richard Tangye writes a long letter to the *Standard*, remarking that the statement is wholly misleading, and setting forth the facts of the case. We extract the following from his letter:—

. . . . At the end of January last we were urgently invited to contribute to the Engineer Employers' Special Fund, on the ground of the heavy strain which had been imposed upon the employers in the recent struggle. On February 10th my company contributed the sum of £500 to the fund. . . . So far from being "at once" returned, the cheque was cashed and paid into the fund, and an acknowledgment sent us by the Federation . . . . . under date February 11th. . . . .

On February 28th—*i.e.*, 17 days after this acknowledgment—Mr. Biggart, the secretary, sent us a banker's draft for £500, with a letter, in which he says: "We have now had an opportunity of reporting your contribution of £500 to our Committee. This is the first meeting held since your cheque was received." He goes on to say his first letter was sent *per incuriam*, but as it contained the distinct statement that he had been desired by his committee to thank us, the explanation of this extraordinary discrepancy must be left to that gentleman. I should explain that long before we gave our contribution to the Federation it was well known to every member of that body that we were not in sympathy with their policy. This fact we expressly stated at an early period of the struggle, and again laid stress upon when handing over our cheque. It was, therefore, with this knowledge that the Federation accepted and thanked us for the gift we had been invited to make. With their reasons for subsequently reversing their own action I am not concerned. . . . .

Manchester Explosion.—At 9 p.m. on 9th inst., an explosion occurred in the roadway at the junction of Withy Grove and Corporation Street, Manchester. A portion of the footpath was blown up, some of the flags being sent through a shop window. We understand that the explosion was due to the ignition of an explosive mixture of coal gas in one of the Corporation electric light junction boxes, and a 6-inch pipe communicating therewith. The mixture was fired, as far as can be ascertained, by a spark due to the failure of some rubber cables in the pipe about 200 yards away. No person was hurt, but several panes of glass were broken.

Institution of Junior Engineers' Conversazione.—The conversazione of the Institution of Junior Engineers was held on Saturday last, 12th inst., at the Westminster Palace Hotel. The gathering was opened by a reception in the large hall by the president (Mr. Aspinall), and Mrs. Aspinall, and the chairman (Mr. H. Bloomfield Vorley) and Mrs. Vorley. An excellent programme of music was executed in the large hall by Mr. W. M. Day's band, and in the music room, the Poppy Pierrot troupe rendered a selection of vocal pieces. Among the numerous items with which the company was entertained, were demonstrations by Mr. Leslie Miller, on signalling without wires, and some instructive and pleasing lecturettes on the Maxim gun by Mr. Hiram S. Maxim. Messrs. J. Thornycroft & Co. showed in operation, during the evening, a model Thornycroft water tube boiler; Messrs. Thorn & Hoddle showed acetylene gas apparatus, including "Incanto" generators; Mr. R. J. Wallis-Jones (Electric Welding Company) exhibited specimens of electric welding work; and Mr. Arthur Rigg showed the variable-stroke hydraulic engine, of which he is the inventor. Mr. J. A. Prestwich's cinematograph displays were, of course, well received, and good use was made of the electrophone room, where, through the courtesy of the Electrophone Company and the National Telephone Company, 16 instruments connected to the various theatres were available. There were also a large number of exhibits in the various halls, and we select for mention models and photographs of a Babcock & Wilcox land boiler; models of Great Eastern Railway locomotive boiler, and parts, liquid fuel injector, express engine, paddle steamer, &c., by Mr. James Holden; photographs of Lancashire and Yorkshire Railway, from the president; Maxim guns, projectiles, &c., from Mr. Maxim; stereoscopic figures of spherical catenaries, &c., shown by Prof. A. G. Greenhill (vice-president) and Mr. T. J. Dewar; also sections, drawings, &c., of the Westinghouse electro-pneumatic signalling apparatus, lent by the Westinghouse Brake Company. A large number of members and friends were present, and an enjoyable evening was spent.

Accumulator Testing.—The following reached us too late for insertion in our "Correspondence" columns:—"In reference to 'Appak's' remarks, your correspondent desires to say that 'Appak' has not comprehended the meaning of the remarks about calculating weight of cells from results of tests on one positive. It is quite easy and accurate to calculate the weight of a 17-plate cell, given the weight of plates and capacity of a 3-plate cell. And also knowing that cells increase in capacity per pound as the plates increase in number up to a certain limit, as shown by an interesting curve in ELECTRICAL REVIEW of December 10th, 1897. 'Appak' may not be able to make these calculations, but your correspondent can, and so can many others. The little experiment with eight plates suggested by 'Appak' is an ancient one, and only proves what is well known, *i.e.*, a 3-plate cell has about half the capacity per pound that a 5-plate has—a fact which does not at all prove that by taking the results of a test on a 3-plate cell we cannot calculate what would be the capacity per pound of the 5-plate cell.—YOUR CORRESPONDENT."

The Electric Cab Mishap.—With reference to the reported burning of an electric cab at Westminster, regarding which the daily press, as usual, made such sensational statements, we learn from Mr. Bersey, of the London Electrical Cab Company, that the cab in question was the one which has been running for the *Daily Graphic* for six months, and during the whole of that time has only stopped one day in order to have fresh rubber tyres put on. What happened on Tuesday was, that the insulation on the wires running under the body between the motor and the controlling switch got rubbed off, and consequently caused a short circuit, and some sparking between the wires. This went on for some little time, until it affected some of the lead connections on the cells, causing them to fuse and melt. Immediately this happened, of course everything stopped, as there was no longer a connection between the cells. There was no question of burning, or the cab being on fire whatever. We understand that the cab was running again on Tuesday night after a delay of only a few hours.

Buckingham Palace Lighting.—In the Civil Service estimates for the coming year, under the heading of Royal Palaces, there is an item of £3,500 for beginning the installation of the electric light at Buckingham Palace.

Lectures.—Mr. George Balfour, A.I.E.E., delivered an illustrated lecture on "Electric Tramways and Railways," in the Gilfillan Hall, Dundee, on 11th inst. A number of town councillors were present, and the Lord Provost presided.

Mr. J. E. Lloyd Barnes, M.I.M.E., was to lecture on Wednesday at the Town Hall, Birkenhead, on "Electric Traction."

On 8th inst. the Right Rev. Monsignor Molloy lectured at the new theatre of the Leinster Hall, Dublin, on "Wireless Telegraphy."

Pacific Cable.—Reuter says that the New Zealand Government regards as premature the proposal of the Eastern Telegraph Company in the matter of the guarantee, and favours the Pacific cable scheme.

Forthcoming Marriage.—A marriage has been arranged, and will shortly take place, between Mr. J. G. Butcher, Q.C., M.P., and Mrs. J. E. H. Gordon, widow of the late Mr. J. E. H. Gordon, who was so well known to the electrical fraternity all over the world.

NEW COMPANY REGISTERED.

British Automotive Proprietary Syndicate, Limited (56,357).—Registered March 4th with capital £55,000 in £1 shares, to adopt an agreement with Automotive Syndicate, Limited, and to manufacture, sell, and deal in electric, steam, gas, oil, and other motors and engines. The subscribers (with one share each) are:—T. E. Garlick, 17, Basinghall Street, E.C., chartered accountant; M. Warren, 17, Basinghall Street, E.C., clerk; W. P. Westell, St. Albans, clerk; J. Lewis, 17, Basinghall Street, E.C., clerk; J. M. Lewers, 17, Basinghall Street, E.C., clerk; C. E. Darling, Longdon Hall, Rugeley, clerk; G. Taylor, 60, Dyne Road, Brendesbury, clerk. The number of directors is not to be less than three, nor more than seven. The subscribers are to appoint the first. Qualification, £100; remuneration, £100 each per annum (£150 for chairman), and a percentage of the profits. Registered by Marshall & Marshall, 3, Lincoln's Inn Fields, W.C.

CITY NOTES.

Notting Hill Electric Lighting Company.

Probably no company in London engaged in the electric lighting business has shown better progress than the Notting Hill Company. For the year 1894 a microscopical dividend of 2s. per share was paid on each £10 share; in 1895 this had advanced to 2 per cent; last year 4 per cent. was returned to the ordinary shareholders, and for the year 1897 a handsome dividend of 6 per cent. has been declared. The success of this company is all the more noteworthy, because it was generally held that the district in which its operations were confined was one of the least favourable in London for an electric lighting concern.

The following shows the increase in the various accounts for the past year:—

Increase.

Capital expenditure.	Output in units.	Working expenses.	Revenue from sale of current.
£14,079	124,182	£1,016	£2,864

The following table gives the cost per unit:—

	1897.	1896.
Total capital expended	£113,184	£99,105
Number of units sold	354,969	230,787

Total	£10,785	0	0	6·9d.

Total cost per unit (exclusive of depreciation and renewal accounts), 2·95d.; works' cost, 1·52d.

St. James's and Pall Mall Electric Lighting Company.

The principal features of the year's work are already familiar to our readers, but a closer examination of the accounts reveals one or two interesting points. The capital expenditure has been increased by a little over £12,000, but the output has advanced from 2,401,431 to 3,028,242 units—an increase of 626,811. The items in the cost of production are, perhaps, not quite as pleasing as last year, though the total cost is slightly less. Repairs and maintenance, during the year have been exceptional, and stand at £5,104, against £2,886 for 1896.

The following table gives the cost per unit:—

	1897.	1896.
Total capital expended	£254,077	£241,328
Number of units sold	3,028,242	2,401,431
Number of lamps connected	126,827	108,803
Revenue from sale of current	£66,376	£53,967
Net revenue	£30,534	£25,339
Average price obtained per unit	5·26d.	5·39d.

Cost of production.	£		Per unit.	1896.
Coal	6,514		·52d.	·50d.
Oil, waste, water and engine room stores	922		·07d.	·08d.

Total	£68,140	0	0	5·26d.

Total cost per unit (exclusive of depreciation and renewal accounts), 2·20d.; works' cost, 1·41d.

Development of Electric Lighting in London.

We give the following from the *Daily Mail* for what it is worth:—The St. James's and Westminster Electric Lighting Companies are asking for powers this session to build a joint station on some land near North Bank, St. John's Wood. It belongs to the Great Central Railway, and the idea of the companies is to relieve the stations at Carnaby Street and Davies Street. It is understood that the sole object of the acquisition is to assist the purposes of the joint companies, and not for competition with other electric light concerns, a rumour to which effect has been of late current. In two years' time both the other stations would be overloaded, and by then the new station is expected to be ready. We should not, however, be surprised to find that an assault was intended upon one of the electric lighting companies, which has hitherto endeavoured to have things very much its own way.

Kensington and Knightsbridge Electric Lighting Company.

The report for the year shows steady and substantial progress. The chairman of the company at the annual meeting referred to a feature in the development of the company's business that appears to us a most encouraging one. There had been an increase in the number of consumers over that of the previous year, although the total increase of lamps was not as large as in the year 1896. This seems to indicate that electric lighting is extending among the less wealthy class of customer, and this is distinctly satisfactory, for it is hardly necessary to point out nowadays that the consumer who keeps a small number of lamps burning long hours is one to be encouraged.

The expenditure for the year is a matter of some £22,000, nearly £17,000 of which has been spent on machinery and buildings. The increase in the output is 383,633 units, which has been obtained by an increase in the total cost of production of £3,216; the gross profits, however, showed an advance from £34,371 to £41,681, practically £7,309. The following table shows the increase:—

Output.	Capital expenditure.	Working costs.	Gross profits.
383,633 units.	£21,997	£3,216	£7,309

The following table gives the cost per unit:—

	1897.	1896.
Total capital expended	£252,162	£230,164
Number of units sold	1,898,362	—
Number of lamps connected ...	137,955	119,950
Revenue from sale of current ...	£41,681	£34,371
Net revenue	£14,639	—
Average price obtained per unit ...	5·25d.	—

Cost of Production.	£		Per unit.	1896.
Coal	5,468		·69d.	—
Oil, waste, water, and engine room stores	909		·12d.	—
Salaries and wages at generating station	3,605		·46d.	—
Repairs and maintenance of buildings, engines, boilers, dynamos, &c.	3,521	{Works' cost 1·69d.}	·45d.	—
Rent, rates and taxes	2,597		·33d.	—
Management expenses, directors' remuneration, salaries of managing engineer, secretary, clerks, &c., stationery and printing, general establishment charges, auditors, law charges, and insurance	3,928		·50d.	—

Meter rents, &c.	1,323	0	0	—
Supply of steam	—			—
Transfer fees	—			—
Other items	17	0	0	—
Total	£43,021	0	0	5·25d.

Total cost per unit (exclusive of depreciation and renewal accounts), 2·55d.; works' cost, 1·69d.

Charing Cross and Strand Electricity Supply Corporation, Limited.

There has been no abatement of prosperity during the past year, and the Charing Cross Corporation may be now ranked among the soundest of the metropolitan supply companies. 34,078 additional lamps have been connected to the mains, an increase of 53·7 per cent. on the lamps connected in 1896. The output also shows a considerable increase upon that of 1896; in fact, some 33⅓ per cent. The capital expenditure for the past 12 months has been, however, somewhat heavy, being, in fact, £48,166. Of this sum, £24,693 has been spent on machinery, £12,017 on mains, and £5,806 on buildings, so it may be taken for granted that the full benefit of this additional expenditure has not yet been realised.

The following table shows the increase:—

Capital expenditure.	Output in units.	Cost of production.	Increase in gross revenue.
£48,166	671.108	£6,283	£9,922

It will be noted that the total cost of production per unit is identical with the figures for last year. Although the item for fuel is higher than last year, we may expect that, when the system is in complete working order, it will be very much reduced.

The following table gives the cost per unit:—

	1897.	1896.
Total capital expended	£357,770	£309,604
Number of units sold	2,615,508	1,944,402
Number of lamps connected	107,522	73,464
Revenue from sale of current	£48,027	£38,105
Net revenue	£18,907	£15,289
Average price obtained per unit ...	4·4d.	4·69d.

Cost of Production.	£		Per unit.	1896.
Coal	10,349		·95d.	·87d.
Oil, waste, water, and engine room stores	997		·09d.	·08d.
Salaries and wages at generating station	5,110		·47d.	·46d.
Repairs and maintenance of buildings, engines, boilers, dynamos, &c.	2,308	{Works' cost 1·72d.}	·21d.	·26d.
Rent, rates and taxes	2,467		·23d.	·25d.
Management expenses, directors' remuneration, salaries of managing engineer, secretary, clerks, &c., stationery and printing, general establishment charges, auditors, law charges and insurance	3,494		·32d.	·35d.
Depreciation of buildings and plant account	—		—	—
Renewal fund account	—		—	—
Total	£24,725		2·27d.	2 27d.

Transfer fees	—			—
Other items	272	0	0	—
Total	£48,881	0	0	4·4d.

Total cost per unit (exclusive of depreciation and renewal accounts), 2·27d.; works' cost, 1·72d.

Dover Electricity Supply Company.

It is yet too early for the accounts of this company to show any beneficial results from the supply of electrical energy for the municipal tramways. It will be doubtless remembered that an agreement exists between this company and the Dover Corporation for the supply of electricity for tramway purposes, on what are undoubtedly favourable terms, as far as the company is concerned. The tramways, however, did not commence to to run before September, consequently, one cannot expect that the company has yet realised to what extent their position will be improved. It is significant, however, that the number of units sold has increased from 154,200 to 234,074, though the lamps that have been added to the circuits, 2,233, are no doubt in a great measure responsible for the increased consumption. The accounts for 1898 will be distinctly interesting, for they will reveal the practical advantages that are likely to accrue from the combined supply of electricity for lighting and tramway purposes. The following table shows the increase in capital, working costs, and output:—

INCREASE.

Capital expenditure.	Output in units.	Working expenses.	Revenue from sale of current.
£11,932	79 874	£892	£2,385

The following table gives the cost per unit:—

	1897.	1896.
Total capital expended	**£62,836**	£50,904
Number of units sold	**234,074**	154,200
Number of lamps connected	**10,187**	7,904
Revenue from sale of current	**£5,059**	£2,674
Net revenue	**£1,178**	—
Average price obtained per unit	**5·16d.**	4·14d.

Cost of production.	£		Per unit.	1896.

County of London and Brush Provincial Electric Lighting Company, Limited.

THE fourth annual meeting of this company was held on Monday at Winchester House, Lord Rathmore presiding.

The CHAIRMAN congratulated the shareholders on the steady progress which had been made by the company since their last meeting, on the good position in which they stood, and on the encouraging prospect which seemed to be opening for them. The net revenue for 1897 amounted to £20,875, as against £5,904 in 1896, while the gross receipts had increased from £8,485 to £25,371. A large proportion of these receipts arose from profits on investments realised. They had derived already a substantial profit from their London stations, amounting to £2,521 from St. Luke's and to £1,281 from Wandsworth. When they remembered what exceptional difficulties they experienced in the preparatory stages, and bore in mind that their two stations were only started for the supply of current during the past year—in the case of St. Luke's so recently as September last—those earnings were on the whole as large as they could reasonably have expected. The remainder of the ordinary share capital had been issued, making the total of capital paid £509,808, and leaving £90,000 which fell due this year. A substantial premium was received on the second issue of the ordinary shares, and this was applied to reducing the preliminary expenses, writing off costs in connection with provisional orders, and in increasing their reserve fund, which now stood at £5,000. The loans against security had been reduced from £53,600 in 1896 to £29,700, The sundry creditors amounted to £58,344, which was nearly all represented by plant, machinery, and cables, and was more than covered by the amount of sundry debtors on the other side of the balance-sheet. As to the assets, a further sum of £141,066 had been invested in their London districts. The preliminary expenses, which stood in 1895 at £18,478, had been reduced from time to time, and now amounted to only £8,800. As to their investments, some changes had occurred during the year, the most important of which was, that they had disposed of their interest in the Bournemouth station. The sundry debtors amounted to £71,545. This was largely in respect of their interest in the Bournemouth and district company, and it had now nearly all been collected. Their metropolitan stations were those to which they looked for their largest profits in the future. They retained an interest in the Bournemouth district, represented by ordinary shares. In the Dover company they still held practically the whole of the ordinary shares, and there seemed to be a good future before it. A dividend of 3 per cent. had been paid on the share capital of the Richmond company, and the whole of this dividend had gone into this company's coffers. The broad policy adopted by the company from the first in dealing with electrical supply for the County of London had been the establishment of two large generating stations—one on the north side and one on the south side of the river—each capable of meeting the wants not only of its immediate neighbourhood, but also of supplying the requirements of other localities for which they had hoped to obtain lighting orders. At the present moment they had by far the largest area of any electric lighting company in London. Their plan was based on the belief that such a policy would be found to be more economical and satisfactory than that of setting up smaller generating stations. He ventured to suggest to the vestries of the smaller areas of London who might be now thinking of embarking on electric lighting schemes of their own to ponder whether it might not be wiser to supply their wants in that direction by means of established companies—their own, for instance, which, owing to its larger preparations for business and its special technical experience, must be able, presumably, to give a more satisfactory supply, and at moderate rates, without any material reduction of its just profits. They had erected a fine station in the City Road, adjoining the Regent's Canal, so that the carriage of their coal and other material would be cheap and easy. The building at St. Luke's was finished, and the plant installed there was capable of supplying the equivalent of 80,000 8-candle-power lamps connected. They had good ground, he thought, for expecting that the demand for electric light in the St. Luke's and Clerkenwell district would steadily increase. For the eastern portion of Holborn the provisional order was confirmed to them in the last session of Parliament, and work having been at once commenced, current was now available. As to the western portion of Holborn, and also St. Giles-in-the-Fields, they had secured the consent of the local authorities to their application for provisional orders, which now awaited the sanction of Parliament. There were several other districts on the north side of the Thames and in the East-end of London, into some of which they had already obtained, while for others they were seeking the necessary authority to enter, and all of which they would be able to supply for years to come from their station in the City Road. So far he had been speaking of electric lighting only; but they were confirmed in their anticipations of a large demand also in those districts for a supply of electric current for motive power. Special mains for the supply of such current had been laid throughout the principal thoroughfares, and he believed that all preparations had been completed, and that that evening the batteries would be charged for the service. Their Wandsworth station was completed, and the plant now installed there had a capacity of supplying more than 40,000 8-candle lamps power connected, while there was space in the building for machinery to supply three times that number. From that vast area a very encouraging demand had already sprung up; and in Camberwell there was already a considerable demand for motive power as well as for electric lighting. The policy involved, no doubt, heavy capital expenditure at first and a certain delay in obtaining a substantial revenue in return, but they had done with large capital expenditure for years to come. They had paid no dividend yet on their ordinary shares. When, however, they allotted 10,000 ordinary £10 shares last December, their market value was £15, and they were allotted at par to their ordinary shareholders in the proportion of one share for three already held, and this was equal to a dividend of about 5 per cent. for the last three years.

Mr. J. B. BRAITHWAITE, jun., seconded the adoption of the report, which was adopted.

A resolution increasing the directors' remuneration to £2,000 for 1898 was then carried.

The Oxford Electric Company, Limited.

THE report of the directors states that the revenue account shows a profit for the year of £3,996 17s. 5d., to which has to be added £13 17s. 6d. (the difference between the receipts from share premiums and the expenses attending the redemption of the old debentures) and £537 7s. 6d., the amount brought forward from last year's account making a total of £4,548 2s. 5d. After deducting £202 15s. 2d. on account of the expenses attending issue of debenture capital, and providing £1,499 1s. 10d. for debenture and loan interest, the available balance is £2,846 5s. 5d., which the directors propose to appropriate as follows:—£500 to a fund to provide for future renewals of machinery and plant, and £2,327 8s. in payment of a dividend at the rate of 5 per cent. per annum upon the capital (the new shares issued in March ranking for dividend, as provided by the prospectus, from the average date of payment of the instalments thereon), leaving a balance of £18 17s. 5d. to be carried forward to next year's account. The £25,000 of 5 per cent. debentures outstanding at the date of last accounts have been redeemed at a bonus of 5 per cent., and replaced by an issue of £35,000 debenture stock at 4 per cent. interest. The premiums received on a further issue of 2,000 shares made in March last exceeded the bonus paid on the redemption of the debentures by £13 17s. 6d., which has been carried to the revenue account. The expenses attending the issue of the new debentures, including the sum of £79 10s. which previously stood to the debit of capital account, amount to £608 5s. 6d., whereof £202 15s. 2d. had been debited to the revenue of the year, and the balance carried forward, to be liquidated out of the revenue of the next two years. The gross receipts have been to some extent affected by a reduction in the price of current to consumers as from January 1st, 1897, but the directors confidently expect that this liberal policy will yield advantageous results in the near future. Since the last report 2,630 8-C.P. lamps or the equivalent, have been connected with the mains, bringing the total on December 31st last up to the equivalent of 21,364 8-C.P. lamps. The plant at the generating station has been increased during the year by a 500-H.P. engine and a boiler of 200-H.P. capacity. A new transformer station has also been equipped in Ship Street, and two additional transformers connected to the system. A line of 3-inch iron pipes has been laid from the works at Osney to a central position in the city, to provide for extensions of the high tension feeding system, and to enable the supply to be controlled entirely from the works. The cost of these additions to plant and extensions has been provided by the proceeds of the 2,000 shares issued during the year.

Chelsea Electricity Supply Company, Limited.

The directors' report states that in October, 1897, an issue of 8,000 ordinary shares of £5 each was made, and was fully subscribed. The final instalment on these shares, due on January 1st, 1898, has now been paid, and a Stock Exchange quotation for the new issue has been applied for. The balance of premium received in 1897 in respect of this issue, after deducting the expenses of issue, amounts to £21,983 5s. 6d., and, following the course adopted in the accounts of previous years, a portion of this has been applied to the extinction of the legal and other extraordinary expenses incurred during the year. The balance remaining, £20,851 15s. 5d., has been placed to the reserve fund, making the total of that fund £36,717 9s. 5d. The sum of £2,000 has been added to the renewals and depreciation fund, out of the net revenue. After deducting this amount, and after payment of interest on debenture stock (£2,700), there remains a balance available for distribution of £11,344 5s. 2d., including £1,526 17s. 4d. brought forward from last year.

The directors recommend that this balance shall be applied as under:—

	£	s.	d.
Interim dividend of 6 per cent. per annum on the preference shares for the half-year to June 30th, 1897 (paid July 1st, 1897)	900	0	0
Interim dividend on 26,000 ordinary shares for the half-year to June 30th, 1897, at the rate of 5 per cent. per annum (paid July 1st, 1897)	3,250	0	0
Dividend of 6 per cent. per annum on the preference shares for the half-year, to December 31st, 1897 ...	900	0	0
Dividend on 26,000 ordinary shares for the half-year to December 31st, 1897, at the rate of 7 per cent. per annum, making a total dividend of 6 per cent. for the year	4,550	0	0
Dividend at the rate of 6 per cent. per annum on the instalments of £1 per share from the due date of the instalment to December 31st, 1897, on the new issue of 8,000 shares	92	1	1
Balance to be carried to next account	1,652	4	1
	£11,344	5	2

The number of lamps connected on December 31st, 1897, was 96,638, an addition of 16,178 during the year. A large part of the capital expenditure has been incurred in the purchase of freehold land in Pavilion Road, and building thereon a substantial sub-station, in the extension of the new generating station at Alpha Place, and also in the purchase of some leasehold property. Considerable amounts have also been spent on generating machinery and on mains to supply the increase in demand.

At an extraordinary general meeting, held on February 2nd last, the shareholders confirmed their approval of a Bill for the compulsory purchase of certain properties required for the development of the business.

House-to-House Electric Light Supply Company.

The tenth ordinary general meeting of the shareholders of the above company was held on Friday last at Winchester House, Old Broad Street, Mr. Henry Ranire Beeton (the chairman) presiding.

The report and accounts having been taken as read, the Chairman said: Gentlemen, in moving the adoption of the report and accounts, I should like to call attention to the fact that the satisfactory features which have characterised the working of our undertaking of late years, have repeated themselves during the past year. The extension in the demand for electricity has continued undiminished, and a further reduction in the cost of production has been effected; so that our increased revenue has again been earned without any appreciable addition to our expenditure, and the increase of profit is larger than in any previous year in the company's history. In regard to the future, the applications so far received from new consumers during the current year exceed those received at the corresponding date last year, and although the cost of production cannot be indefinitely reduced, there is no reason to believe that finality has been reached in this particular. In order to obtain the satisfactory results which our accounts disclose, we have had to adopt, wherever it was possible to do so, the best machinery and methods which advancing experience has made available. This is no reflection upon our system of supply, which, I think, we are justified in regarding as the best suited to a district such as ours, but is a necessity incident to all systems in the earlier stages of the industry. Already our works' cost is nearly as low as those of other metropolitan supply companies whose output is four and five times larger than ours, while our capital outlay per unit of productive power compares most favourable with that of our neighbours, notwithstanding that most of them are more favourably situated than we are. The credit of this position, of which we may justly be proud, is largely due to the ability and devotion of the company's engineer and manager, Mr. Bowden, to whom the thanks of the shareholders are due. The effect, however, of the rapid development in the methods of supply and distribution during the past eight years in which the foundation of our business has been laid, has been that some of our plant has been superseded in the process. In these circumstances, our capital account has had to suffer somewhat for the benefit of our revenue account, and we have frankly recognised in our report that the normal provision for depreciation must accordingly be supplemented in future years if our capital is to remain intact when our undertaking falls in to the local authority under the purchase clause of our provisional order. I am happy to say, however, that so far as we can ascertain our loss of capital from this cause, it is already much more than compensated by the value of the goodwill which we possess to-day, and that as the value of our goodwill declines with the lapse of our concession, such loss can be provided out of revenue without any additional burden on profits, owing to the extinction of the preliminary expenses which has now been accomplished. Before concluding my observations, I should like to call attention to a plan which we have recently inaugurated for advancing the popularity of the electric light in our district, which we commend to the notice of our consumers and to the emulation of our neighbours. Alone among the electric lighting companies in the metropolis to-day, we are prepared to give householders a limited installation, not only free of all initial expense, but free from any additional charge for electricity. We believe that when consumers realise that they can enjoy the electric light without incurring any capital expenditure, and especially leasehold consumers whose expenditure would not benefit their own property, many will be disposed to adopt the electric light in preference to gas, and as we can make a larger profit on the same number of lights in the form of many small installations than in the form of fewer large installations, it will pay us to expend the capital necessary to extend our business in this way.

Mr. R. A. Germaine seconded the motion, and the report was adopted.

The retiring directors and auditors having been re-elected, the proceedings terminated with a vote of thanks to the chairman for presiding.

The Windsor Electrical Installation Company, Limited.

The directors' report states that the business of the company is progressing satisfactorily. The number of lamps installed on December 31st, 1897, was equivalent to 4,985 of 8-candle power; since that date 395 have been added. In the course of the year a new engine, twice the size of the original ones, has been added, and the storage cell capacity has also been doubled. Extension of mains have been made in St. Leonard's Road, Osborne Road, and King's road. The net profit for the year is £1,256 16s. 7½d., as shown on the net revenue account, No. 4, and out of this sum the directors recommend that a dividend of 4 per cent., free of income-tax, be declared on the paid-up capital of the company, the dividend on the new shares being calculated from the dates of allotment and call. This will absorb £652 7s. 4d., leaving a balance of £604 9s. 3½d. to carry forward. The directors have now been in office for two years without any remuneration whatever, and in view of the very satisfactory progress of the company, they will, at the general meeting, ask the shareholders for a vote on account of their past services. Mr. A. W. H. Good resigned his position as secretary of the company in the early part of the year, and your directors did not consider it necessary to appoint another permanent secretary, as Mr. A. W. Shipley, in addition to being a director of the company, kindly accepted the position of managing director, and the board consider themselves very fortunate in securing his valuable services. It is proposed to issue the remaining capital—£5,000—during the current year. The directors recommend that the shares be issued at a premium of 2s. 6d. per share, and any shareholders desiring an allotment should apply at the company's offices for a form of application. The allotment will be *pro rata* to existing holdings, but any shareholder not applying within one month of the date of this report will be deemed to have renounced his right to an allotment. Current is now being supplied at 7d. per unit, but the directors hope to reduce the price to 6½d. when 8,000 C.P. lamps or their equivalent are installed. This reduction in Windsor is equal to 3d. per 1,000 feet of gas.

South London Electric Supply Corporation.

The first report of the directors, with accounts to December 31st last, to be presented to the ordinary general meeting to be held in London on Monday, states that the works of the corporation are proceeding in a satisfactory manner. The first subject which claimed the board's attention was that of obtaining a suitable site for the central station and dust destructor, which, by virtue of an agreement with the vestry, had to be approved by that authority. This presented much difficulty, and caused unavoidable delay. The inconvenience was, however, fully compensated for by the ultimate acquisition of the most favourable site for the purposes of the corporation within the parish of Lambeth. The land is freehold, and consists of three acres on the north-west side of the London, Chatham and Dover Railway, between Loughborough Junction and Denmark Hill stations. Possession was obtained at Michaelmas, 1897, when the contractors, Manlove, Alliott & Co., Limited, were instructed to proceed with the erection of the necessary buildings and dust destructor. Arrangements have been made by which current is being obtained from a neighbouring electric supply company, pending the completion of the central station, and thus the nucleus of a promising business is being formed. About two and a half months have elapsed since a portion of the mains were made available for a supply of current. The total number of 8-C.P. lamps for which energy has already been applied for amounts to 2,659. The whole of the issue of share capital offered last March, amounting to £325,000, has been subscribed. This places the corporation in a strong financial position, and obviates the necessity of curtailing the contracts which at one time appeared inevitable. The action of the board in placing the balance of the original issue which was not applied for when the corporation was brought out has been somewhat criticised. The directors are satisfied that they acted in the best interests of the corporation, and are confident their action will be supported by the general body of the shareholders. As so short a time has elapsed since the commencement of operations, and no electric supply had been made up to the end of 1897, the accounts merely take the form of a balance-sheet to December 31st, showing the position of the company at that date. Mains already laid are shown on maps which can be seen at the corporation's offices, and amount in all to 21 miles laid in about 8 miles of streets. The necessary machinery and plant is being constructed as rapidly as possible.

Sheffield Electric Light and Power Company.

The report of the directors for the past year states that the net profit, including a balance of £99 brought forward, is £11,492, which it is proposed should be appropriated as follows:—Interest on debentures, £1,125; in payment of a dividend of 12½ per cent., free of income-tax, £9,464; and carry forward £903. The last issue of shares at £2 premium was wholly taken up, and realised a premium of £3,792, which was applied to costs of increasing capital, £200; to depreciation fund, £1,903, making that £6,643; and to reserve, £1,689, bringing that fund up to £2,970. On January 1st, 1897, the price of current was reduced from 6d. to 5d. per unit, and an increased demand had followed. The amount derived from the sale of the current during the five completed years of the company's operations were—1893, £3,555; 1894, £4,849; 1895, £6,935; 1896, £11,258; 1897, £14,319. During the year £19,980 had been expended upon machinery, mains, and other appliances, being £1,600 more than in the preceding year. In consequence of the difficulty in obtaining new machinery from English manufacturers, owing to the dispute in the engineering trades, the directors in July last notified their inability to accept new customers for attachment before Christmas. The difficulties are now removed, as new machinery had been laid down. At the annual meeting the shareholders will be asked to approve of an agreement for the sale of their undertaking to the Corporation. The capital expenditure is fixed at £124,472, and the Corporation agrees to pay £320 Sheffield 2½ per cent. redeemable stock, or £213 8s. in cash for each £100 of the capital property expended by the company. The sale takes place as from December 31st, and until its completion the company is entitled to a dividend of 10 per cent. per annum upon their paid up capital. The directors think the terms proposed are fair and equitable, and they advise the shareholders to accept them.

Hastings and St. Leonards Electric Light Company.

The directors' report congratulates the shareholders upon the increasing business of the company, and points with much satisfaction to the fact that the increased income has been obtained at a very small increase of cost, the receipts for the past year having exceeded those of 1896 by £1,633, whilst the expenditure or works' cost has only increased £157. This result has been obtained by constant watchfulness of the staff, in the expenditure of fuel, and by improvements made in the machinery, whereby greater economy has been possible. Since the last ordinary general meeting the Corporation has taken and paid for the mains, lamp-posts, and other plant relating exclusively to the public lighting, and consequently the repairs to, and renewals of, such plant now fall on the Corporation, although the company is still supplying the current, and will probably continue to do so for some time longer. The directors have also (with the sanction of the shareholders) entered into a provisional contract with the Corporation for the sale of the undertaking, and the Corporation is applying to the Board of Trade for a provisional order to enable it to carry the contract into effect, but, in the meantime, the directors are carrying on the business for the benefit of the shareholders, as if no such contract existed. The result of the past year's trading is exceedingly satisfactory, and shows a net profit of £1,990 18s. 4d., out of which the directors recommend a dividend at the rate of 6 per cent. (which will exhaust £1,633 4s.) to be paid; £300 to be placed to reserve, and the balance of £57 14s. 4d. to be carried forward.

Isle of Man Tramways and Electric Power Company.

The annual meeting of this company was held at Douglas yesterday week.

The directors' report submitted stated that the balance available was £11,155, and recommended dividends at the rates of 6 per cent. per annum on the preference and 7 per cent. per annum on the ordinary shares.

Mr. A. Bruce, chairman of directors, in moving the adoption of the report and accounts, said the extension of the electric system from Laxey to Ramsey would be open next July, and he anticipated that this would be a source of considerable revenue to the company.

The motion was adopted.

Messrs. A. Bruce and F. G. Callow, the retiring directors, were re-elected, and Messrs. William Aldred, Son & Co., Manchester, were re-appointed auditors.

Birmingham Electric Supply Company.

A meeting of this company was held last week at Birmingham.

Mr. Buckley, chairman, in proposing the adoption of the report, congratulated the shareholders on their receiving, for the first time in the history of the company, a 5 per cent. dividend. The prospects of the future were very hopeful, as was shown by the continued increase in the business. During 1895 they supplied 18,199 lamps; in 1896 the number was 25,876, and last year 39,232. Their supply of current in 1895 was 490,000 units, 1896 756,000, and last year 1,133,000 units. Therefore he thought he was justified in saying that the company was created for a proper purpose, and that there was a field for their operations. By the aid of wall diagrams he then showed to the satisfaction of the shareholders how the supply of their light was extending not only among manufacturers, but also to the residential parts of the city. This increased output had necessitated enlargement and additional plant at both the Dale End and Water Street premises, and he thought that they had reason to look upon the future with the greatest satisfaction. With regard to the proposal of the Corporation to take over the concern, one of the council committees was looking into the matter to see if it was advisable to recommend the purchase; and the shareholders would therefore see that it was impossible for him to make any statement on the question at present. It would be wrong to the Corporation and inimical to the company. Whatever was done, however, would be subject to the approval and ratification of the shareholders. As to the increase of capital, the directors would in this case also consult the shareholders as to the time when the new shares should be issued. The motion was then adopted.

Crompton & Co., Limited.

We have received the following circular signed by Mr. John Trotter, chairman:—"The directors have to inform the shareholders that in consequence of certain differences of opinion between themselves and Mr. J. F. Albright as to the management of the company's business, Mr. Albright is relinquishing his position as a managing director, and has also informed the board that as soon as may be convenient to the company, he is desirous of resigning his position as a director. The directors regret that this course should have become necessary. To provide for the future management of the company, the directors have appointed Mr. F. R. Reeves, the company's secretary, to the post of general manager, Mr. R. E. Crompton continuing to superintend the technical part of the company's business. The directors are pleased to be able to inform the shareholders that arrangements have been made by which Mr. Albright undertakes for 12 months to give the company all advice and information reasonably in his power."

Stock Exchange Notices.—Application has been made to the Stock Exchange Committee to appoint a special settling day in and to grant a quotation to—W. T. Henley's Telegraph Works Company, Limited—Further issue of 2,500 ordinary shares.

The Stock Exchange Committee has appointed Wednesday, March 23rd, a special settling day in County of London and Brush Provincial Electric Lighting Company, Limited — Further issue of 10,000 ordinary shares of £10 each, £2 paid, Nos. 30,001 to 40,000; and has ordered to be quoted in the Official List:—County of London and Brush Provincial Electric Lighting Company, Limited—Further issue of 10,000 ordinary shares, Nos. 30,001 to 40,000.

The Direct Spanish Telegraph Company, Limited.—The board has decided to recommend the payment of the dividend at the rate of 10 per cent. per annum on the preference shares, and a dividend, free of income-tax, at the rate of 4 per cent. per annum on the ordinary shares, both for the half-year ended December 31st, 1897.

Chelsea Electricity Supply Company, Limited.—The annual meeting of this company was held yesterday afternoon, at Cadogan Gardens, S.W., for the adoption of the report and accounts for 1897. A report will appear in our next issue.

TRAFFIC RECEIPTS.

The Bristol Tramways and Carriage Company, Limited.—The receipts for the week ending March 11th, 1898, were £2,259 13s. 2d.; corresponding period, 1897, £2,125 17s. 6d.; increase, £133 15s. 8d.

The City and South London Railway Company.—The receipts for the week ending March 13th, 1898, were £1,077; week ending March 14th, 1897, £1,031; increase, £46; total receipts for half-year, 1898, £11,796; corresponding period, 1897, £11,806; decrease, £10.

The Cuba Submarine Telegraph Company.—The receipts for the month of November were £3,413, as compared with £4,545 in the corresponding month of last year.

The Dover Corporation Electric Tramways.—The receipts for the week ending March 12th, 1898, £100 5s. 9d.; total receipts to March 12th, 1898, £1,048 11s. 6d.

The Dublin United Tramways Company.—The receipts for week ending Friday, March 11th, 1898, were £381 4s. 1d.; corresponding week last year, £392 11s.; decrease, £11 6s. 11d.; passengers carried, 65,867; corresponding week last year, 63,023; aggregate to date, £3,975 18s. 5d.; aggregate to date last year, £4,305 18s. 6d.; decrease to date, £330 5s. 1d.; mileage open, 8 miles. Cars, 1898, 209; 1897, 227. Miles, 1898, 18,887; 1897, 17,865.

The Liverpool Overhead Railway Company.—The receipts for the week ending March 13th, 1898, amounted to £1,330; corresponding week last year, £1,280; increase, £50.

The Western and Brazilian Telegraph Company, Limited.—The receipts for the week ending March 11th, 1898, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £2,996.

STEAM RAISING BY WATER TUBE BOILERS.

The Gloucestershire Engineering Society was recently selected by Mr. H. W. Kolle, as the audience to which to expound his theories of the water tube boiler. Naturally Mr. Kolle is biased in favour of water tube boilers, and considers them as near perfection as boilers have yet arrived. It may be well, therefore, to review the eight requirements of a perfect steam boiler as enunciated by him. These are far more than eight in number, but we give them as arranged under eight heads, but divested of the curious lack of the rules of elementary construction which seems to cling to so many technical descriptions. They are as follows:—(1) Best materials for construction, perfect workmanship, durability, highest class fittings. (2) Great margin of strength, construction free of expansion stresses. (3) Sectional water space so arranged as to avoid general explosion. (4) A combustion chamber arranged to secure complete combustion before escape of gases to chimney. (5) Heating surface at right angles to the gas currents. (6) Constant and thorough circulation. (7) A steam and water capacity sufficient to prevent sudden change of pressure or water level. (8) Accessibility of parts for cleaning or repairs.

As the above requirements are claimed to exist in the Babcock boiler *par excellence*, we may not unfairly follow the claims and see if they are all substantiated. Of the first requirements there is no difficulty in using the best possible materials and workmanship, and the highest class of fittings. This is merely a matter of choice. The question of durability is an open one. Perhaps the worst fault of the water tube boiler is the short life of its internal brickwork or of its lower tubes when water is hard. We hope there is now no further use of cast-iron in any water tube boiler, but for a long time there was far too much cast-iron in the ends of the steam drums and in the tube headers, and the claim for best materials has at most only lately been tenable.

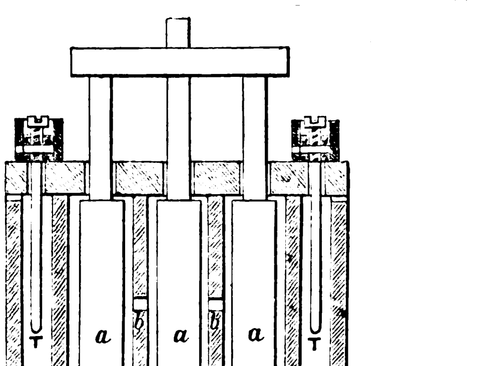
Claim (2) for large margin of strength can only be tenable if all parts are of wrought-iron or steel, and if any cast-iron is still used must be disallowed. Advocates of water tube boilers, while claiming great strength because of small diameter of parts, have thrown away such advantages by resorting to the wholly unsuitable metal cast-iron. Stresses from unequal expansion are provided against fairly well by the water tube arrangement. Claim (3) is fairly well earned. Claim (4) cannot be considered tenable. The gases from the fire rise up directly among a nest of cold tubes, and then enter the so-called combustion chamber—so-called by courtesy only. A combustion chamber placed behind a lot of water pipes cannot act as a combustion chamber if the pipes have done their duty. Moreover, the ordinary arrangement of the furnace is anything but good. There is no bridge, and the products of the fire rise directly amongst the tubes above them. A fire cannot be smokeless unless the products from it are mingled by sweeping over the whole fire surface and pass, via the bridge, to the combustion chamber beyond. Experience with Lancashire and Galloway boilers proves that even under the best conditions the presence of cross water pipes in the tubes beyond the bridge wall will induce smokiness. The water tube boiler as arranged in the Babcock type, must either burn smokeless fuel, or it must have its furnace arranged with an over-arching firebrick roof, so as to compel the gases to travel somewhat as in other forms of boilers. Combustion should be complete before the tubes are reached, or there will be very little later chance of securing this desirable result. As to claim (5) there is probably no particular value in this arrangement. Gases travelling across tubes only impinge on one-half the tube, and the other half is untouched. It is probably better that the gases should travel with the tubes, completely enveloping them. Claim (6) is fairly to be maintained. For stationary work the arrangement of sloping tubes is such as to induce continuous circulation. Claim (7) is one on which great differences of opinion prevail. In a battery of boilers the smallness of capacity of each individual item is perhaps of little consequence. It is when there is but one boiler that the lack of steadiness becomes apparent and the water tube boiler gives least satisfaction. Of claim (8), that of accessibility for repairs, this, of course, depends on the arrangement possible with the seating. With ample space it can be secured. Our author is apt to lay far too much stress upon the heat transmission being hindered by the thick plates of the furnaces of large shell boilers. A single homogeneous thick plate does not readily burn; lap joints may burn, but it is the air space at the lap which causes this. Water tubes, though thin, often tear open in a most disastrous manner, and are not looked on as particularly safe by boiler insurance companies who prefer shell boilers despite Mr. Kolle's statement that they explode almost every day. Moreover, this statement is not borne out by fact. More water tube boilers explode per cent. of these at work than shell boilers. Nor have water tube boilers proved themselves to be economical as compared with shell boilers. Probably the marine class of land boiler as now made and arranged affords the best example of fuel economy and economy of space and bricks. The setting of the water tube boiler is unfortunately somewhat tender and gives rise to great cooling effects from air leakage. In a less but similar degree the Lancashire boiler is exposed to the same losses. We have seen a good many tests reported of water tube boilers, but none to substantiate the claim for superiority over any other type. True a report was published which claimed, we believe, 13½ lbs. evaporation although the chimney temperature was high, but who believed it? Water tube boilers have a future. There are places, thanks to the follies of architects, where water tube boilers are almost compulsory. At the same time, there is room for much improvement in their construction. The makers of them must get over that idea of small diameters. They make it a question of salvation, and it has not tended to better materials. Large shell boilers have had to face big pressures. No pandering to the devil for poor materials has been possible with them. Where a man has to deal with 200 lbs. pressure in a 12 feet shell he is obliged to be on the alert for good materials, but there is an idea that anything will do for 4 inches, hence the employment of cast-iron and the talk about the safety of small diameters. We fear this has to bear some of the responsibility for split tubes. It is far better to live up to a high pressure than to live down to a small diameter. While many engineers object to water tube boilers because of their small contents, others like them because they soon respond to a forced fire. Later practice seems to favour a combination of shell and water tube boilers so as to secure both the staying power and the sudden response to a pushed fire. Our author looks to the universal adoption in the near future of the water tube boiler and the superheater with high pressure. Water-tube boiler makers seem to have forgotten that the stress of present day pressures on the steam drums of water tube boilers is greater than the stress a few years back on shell boilers, which were then declared to have seen their last days, yet, if judged by the boiler of to-day, were only in their infancy. It is not safe to prophecy too closely on the limits of mechanical engineering.

THE SOCIÉTÉ INTERNATIONALE DES ELECTRICIENS.

The monthly sitting of the Société Internationale des Electriciens was held on March 2nd, 1898, at 8.30 p.m., with Dr. D'Arsonval in the chair.

The Secretary read the report of the last meeting, presented the new members, and spoke of the works published. The president announced the death of M. Gauthier-Villars, and expressed condolence. The committee proposed the following candidates for the official elections that will take place at the next meeting: President, M. Violle; vice-presidents, Messrs. Clérai and Monnier; treasurer, M. Violet; secretaries, Messrs. Abraham and Grosselin.

First, M. P. Janet presented, in the name of M. Bouchet, various interrupters and circuit breakers based on a new mode of breakage. In a box made of insulating material are arranged two cavities separated by an insulating partition; they are filled with mercury up to a



certain height; if a plunger is inserted into each cavity, the mercury rises, flows over the insulating partition, and closes the circuit. In the same way, in withdrawing the plungers, the mercury separates, returns into each cavity, and cuts the circuit. It might be feared that the mercury, bringing impurities with it, would leave a trail behind it; but experience has shown that after a long period of working—1,000 breaks, for instance, the traces left behind by the mercury were not sufficient to close the circuit.

On the basis of the above principle the inventor has constructed various models of interrupters. It is only necessary to put a lid on the box of insulating material; in the centre is a lever for working the plungers. This lid has on its sides two metal rods connected with external terminals. The mercury, as it rises, touches these rods and closes the circuit; we therefore get closing and breaking at three points.

M. Barbarat has arranged an interrupter with three plungers, *a*, *a*, *a*, for high tensions (see illustration), and with two insulating partitions, *b*, *b*. This apparatus has been tried with alternating currents at 12 amperes and 3,000 volts on the sector of the Champs Elysées. Magnetic circuit breakers have also been constructed with this mode of breaking. For this purpose a rod of iron is connected with the dippers, and is displaced within a solenoid traversed by the current. The mechanism is arranged so that the action of the electro-magnet on the armature is balanced at the beginning by the weight. As soon as the movement has begun, two springs placed at the sides and immediately set free, continue it, and raise the rod so as to bring about the breaking.

Various other instruments have been constructed, in particular an interrupting circuit breaker, and minimum circuit breaker. Two electromagnets have also been arranged one above the other; one to make and one to break the circuit. Thus the interrupter can be worked from a distance. M. P. Janet has worked in this manner the interrupter of a circuit of 100 lamps.

M. Barbarat then described the new underground cables with air insulation employed by the Telephone Administration of Paris. These cables are insulated with paper, and the insulation is ensured by injecting from time to time dry air under pressure. For this purpose, the compressed air is supplied by the compressed air company; it passes over chloride of calcium, and is sent into each cable by means of taps. This dried air removes every trace of dampness and ensures the insulation. Sometimes the operation can be facilitated by sending a workman to heat it on the spot.

These cables have been tried over long telephonic systems, and have given good results.

CROWDUS STORAGE BATTERY.

The following is the description of this battery referred to in our "Correspondence" columns, and is apparently a copy of a patent specification:—

This invention relates especially to that type of accumulators or secondary batteries known as the "heterogenous" formation, in which elements are formed by applying lead salts mechanically to conducting supports.

The objects of this invention is to provide a simple, economical and efficient secondary battery and process for manufacturing the same. A further object of this invention is to increase the efficiency of conversion between charge and discharge, and most of all to decrease the weight of the cell without impairing its commercial value, and consists principally in the improvement of the structure of the metallic supports for holding the active material and in the successful adaptation of the metal aluminium as a substitute for lead in the negative plate. It consists, further, in the method of forming the spongy lead of the negative element. It consists, further, in the electrolyte employed in the cell. It consists, further, in the method of electrically connecting the elements of the battery together so as to secure a uniform and equal electrical and chemical action over all parts of each plate. It consists, further, in the arrangement of the insulating and bracing separators that are arranged between opposing plates; and it consists, finally, in the processes, features, combinations and details of construction hereinafter described and claimed. In the art to which this invention relates, it is well known that many different kinds of conducting supporting plates and grids have been designed to prevent the active material from falling out, and also to guard against buckling of the plates, but as is also well known, these plates have not secured these results in the most economical or commercial manner. In order to prevent the warping or buckling of the supporting plates, manufacturers and inventors have attempted to prevent the same by hardening them with alloys and by using an increased weight of lead, the increase of the lead being such that the metallic support presented the largest percentage of the plates, while the real active proportion thereof was relatively small.

It is well known that the attempts to use aluminium as a support for the lead paste or active material have failed for the reason that paste does not adhere readily to the aluminium, and as a consequence fell away therefrom, so that the attempt to use such material in storage batteries has been abandoned, and such material has never entered into commercial use in the art.

My invention is intended to obviate these objections and to provide simple, economical, and efficient secondary batteries of very light and large capacity.

In experimental use and tests I have discovered that the hitherto damaging results from the expansion of the lead salts of positive plates can be turned to good effect by using a thin or mechanically weak rolled lead conducting support, which is free to expand under pressure from the salts, but has its expansion directed principally in straight lines parallel with the face of the plate, that is, the plate may stretch equally in all directions so that there is no tendency to buckle. I also prevent the buckling and increase the rigidity of the plates by inserting vertically corrugated and perforated insulating separators between each pair of elements in the battery.

In constructing a secondary battery in accordance with these improvements, a positive plate is made of thin rolled sheet lead and the same is provided with a series of rectangular or elongated perforations. The supporting plate is provided with terminals at the top and bottom portion thereof so that plates of the same polarity may be electrically connected together at the top and bottom, and thus ensure uniform electrolytic action.

The ribs formed by and between the elongated perforations are bent alternately to opposite sides of the plate, so as to form longitudinal recesses substantially the entire length of the plate, and openings on each side thereof, to hold the active material which consists preferably of a specially prepared hard but porous paste of red lead. This arrangement permits of a very light plate, the presenting of a large active surface, and a greater amount of active material than any other form of construction.

In order to make the improved negative element I use a plate similar to the plate above described in connection with the positive element, with the exception that I use the metal aluminium for the supporting plate, instead of lead, and the same paste for active material by placing the material in the plate, it is locked therein from side to side and throughout its entire length as in a cage, and prevented from falling out, while at the same time the surface of the active material represents a larger percentage of the surface of the plate than ever accomplished before, thereby greatly increasing the surface of the active material and the output of the plate, the weight of the cell being also largely decreased per unit of work.

In practice the weight of my positive lead support, when compared to the active material upon it, is as 1 is to 2, a result never practically obtained before.

The elements are connected together by bending the terminals substantially at right angles to the plate and connecting the plates of similar polarity to each other by means of rivets for the negative plate, and also by autogeneous soldering in the positive plate. The sets of plates are then immersed in the special forming bath, consisting of an aqueous solution of about one-third saturation of sulphate of zinc with 15 per cent. by volume of sulphuric acid.

In this solution I place the plates to be formed, suitably arranged between sheet lead anodes as dummies, and pass a current of about 1 ampere for every 3 square inches of the plates to be formed. On passing the current to the plates, the sulphate of zinc is decomposed, depositing pure zinc upon the negative pole plates, which is resolved from the plate as fast as it is deposited by the sulphuric acid of the solution, thus producing a quantity of hydrogen. By the reducing action of the hydrogen the oxide of lead is rapidly converted into spongy lead. By this process the time of formation is reduced to about two hours, about one-fifteenth of the time required in the processes in actual use at present.

By this method of forming the elements, the dissolved zinc is returned to the solution so that the same solution can be used over and over again for an indefinite period. I have found in experimental tests that the positive plates when first formed into negatives of spongy lead by this process, and then into positives, will give almost their full output on the first discharge, while the old methods require several charges and discharges before the positive plates are fully formed. I therefore also quicken and cheapen the formation of positive plates by the use of quick negative formation.

After formation the elements are placed in the battery, and in order to strengthen and insulate the plates and prevent warping or buckling of the same, I insert between the opposing pairs of plates a corrugated insulated perforated separator which touches such plates at their inactive portions.

By this arrangement no active material is covered by contact with the insulated rubber separator and the internal resistance of the cell is thereby greatly reduced. A ⊤-shaped terminal lug of lead is then secured to the terminal of the positive lead plates and a similarly shaped lug aluminium to the aluminium terminals of the negative plates to which the circuit wires are intended to be attached. It is well known in this art that each time a cell is recharged the negative element decreases in capacity, and that after a time a reversal of the polarity of the positive and negative elements is necessary to bring the cell back to its original capacity. This is avoided and the efficiency of the conversion increased between charges and discharges by adding to the usual sulphuric acid electrolyte (with which all batteries are supplied) a very small proportion of sulphate of zinc, just sufficient to hasten, as described in the former bath, the restoring of the negative element so that its full capacity is restored fully as quickly as that of the positive element.

In the construction of storage batteries all builders connect the elements together by a terminal at the top end, and at one point only. I have discovered in connecting the elements in this manner that in the charge or discharge of the battery, the escape of the current to and from the positive and negative plates is greatest nearer to the terminal lugs, and that it gradually decreases to the more remote points. This action brings about uneven electrolysis upon the plates, to the extent that one portion of the plate (that nearest the terminal) is exhausted or restored quicker than the more remote portions, in consequence of which the capacity of the battery is decreased below the capacity of the active material. It also produces partial polarisation and unequal expansion, and consequently distortion or warping of the plates. In my construction, I remove these objections and obtain a much more uniform electrolysis on every portion of the plate, by connecting the plates of similar polarity at two or more points below the line of the electrolyte. It will be understood, however, that instead of using two terminals, one only may be used, and that one extending nearly the entire length of the plate, or three terminals or even more may be used. In further carrying out the benefits derived from the above described points, the plates of opposite polarity are placed in juxtaposition with each other, so that the connected edges are on opposite sides of the pile. Further, in the use of batteries, the terminals of the plates, or the elements above or outside of the electrolyte are destroyed by the sulphating of the lead, due to the combined corrosive action of the air and acid, and to overcome this, heavy lugs are resorted to. I avoid this objection by completely immersing the terminals of the elements at the point where they connect, so that I can successfully use thin plates in my elements where hitherto destructive sulphating has made it impossible.

TEST OF THE CHICAGO STORAGE BATTERY ROAD.*

(*Concluded from page* 348.)

Data on Batteries Obtained at the Time of Power House Tests.

Two complete power house tests made on November 5th and November 26th, 1897, showed the amount of coal required to deliver a kilowatt-hour upon the switchboard. At the same time a complete log of the operation of the battery charging pit was kept, which shows the history of each battery for the entire time of the test. In the test made November 5th the batteries were charged by the "three-voltage" method, but on November 26th the station was operated with one generator, and but one voltage was used to charge the batteries. During the latter part of this test the tracks became covered with ice, due to a sleet storm, and it became necessary to change the batteries every half trip, which will account for the shorter time of charging indicated upon the latter part of the power station log of the test, and also the smaller average number of miles per trip shown November 26th. The data obtained at the charging tables were checked up with the conductors' reports. These reports show the number of the car, the time occupied by each trip, the length of the run, and the number of the battery used. The following table shows a summary of this information for the two days. This table shows the battery mileage for each day from the time of starting the road in the morning until the last trip at night.

Table of Battery Mileage.

Average miles each trip		16·56	...	13·56

This table shows the actual number of miles which the batteries ran the cars on the two days. In addition to this, batteries were used to operate the auxiliary motors of the plant. These motors are upon the transfer carriage used to handle the batteries in the charging pits, and upon the transfer carriage used to move the cars in the car barns. No record was obtained of the power used by these motors. A recording wattmeter was secured to place in these auxiliary circuits, but unfortunately it was injured in transportation, and could not be used. An effort was made to obtain an average value of the power used for each operation by means of readings made at

* *Street Railway Review.*

intervals of two seconds upon standard volt and ampere meters, but owing to the sudden fluctuations the data obtained were unsatisfactory. However, as the power used in the operation of handling the batteries in the pits and the cars in the barns may properly be charged to the operation of the cars, the total amount of energy delivered to the charging tables divided by the actual car mileage will give the total power required per car mile. With the data at hand, however, this entire energy cannot be exactly divided into the amount used in the barns and the amount used on the road. The former amount will be a very small proportion of the latter, but this proportion will increase as the average length of battery trips decreases.

The power delivered to the switchboard and the amount of coal required upon November 5th is shown in the records of the test made that day. The power delivered upon November 26th was obtained for nine hours from the records of the test made from 3 p.m. to 12 m., and for the remainder of the day from the charts of the recording ammeter. The readings of this ammeter were carefully compared with the readings upon a standard ammeter, and found to be correct. These ampere readings were multiplied by the value of the average voltage found upon the test made that day, and the resulting watts added to those obtained during the test.

The following table shows a summary of the results of the two days' run:—

Date of test	Nov. 5th	Nov. 26th
State of weather	Rainy	Rainy and cold
Kilowatt-hours delivered to switchboard	2,638	2,895
Kilowatt-hours used by cooling tower motor	151	174
Net kilowatt-hours delivered to charging bus bars	2,487	2,721
Total number of car miles ...	1,821·8	1,668.4
Kilowatt-hours on switchboard per car mile	1·87	1·63
Pounds of coal per net kilowatt-hour	6·9	6·44
Pounds coal per car mile ...	9·45	10 50
Cost of coal per ton	$1.90	$1.90
Cost coal per net kilowatt-hour	·00655	00611
Cost coal per car mile	·00897	·00996

It will be noticed that although the cost of a kilowatt-hour upon the switchboard was less in the second test, the cost of fuel per car mile the same day was something more than in the test November 5th. This result is due to the fact that the kilowatt-hours required per car mile were greater in the second case. The difference in the amount of energy required per car mile is to be explained by the presence of a coating of ice upon the rails during the latter part of the day (November 26th). It is unfortunate that a freezing sleet-storm should have occurred at this time, though the results of the test indicate to a certain extent the amount of power required to operate the road under adverse conditions. Owing to the storm, the results of the two tests do not furnish a fair basis for a comparison of economy of the two different methods of charging the batteries.

Efficiency Test of Battery on Car.

This test was made November 8th, 1897, and was made to determine the efficiency of a battery under actual operating conditions. The battery was charged in the regular way by means of the three-voltage method. It was then discharged while making a round trip, and was then placed upon the charging table and again charged, thus giving two charges and one discharge to determine the efficiency. The battery used was one which had operated at that time over 8,000 miles, and was taken for the purpose of this test immediately after it had made a trip similar to the one upon which it was tested.

The current and voltage upon the two charges were obtained by means of standard instruments, and readings were taken every five minutes.

The observations made upon the car while the battery was discharging consisted in taking voltage and ampere readings every five seconds, while the car was in motion, the time between stops and the length and location of each stop, and a continuous record of the speed.

The voltmeter was a standard Weston instrument, and was connected across diagonal corners of the battery tray.

The voltmeter was so connected that it gave the voltage at the battery terminals for each combination. The car tested was 20 feet long in the body, 30 feet long over the platforms, and had a seating capacity of 28 passengers. The car weighed 13½ tons with the batteries, the batteries and trays adding about 4 tons to the usual weight of a car of that size.

The motor upon the car was a 50-H.P. Walker four-pole series motor. The entire current used at any one time passed through the armature, so that the ammeter was inserted in the positive brush leads. The ammeter used was of the round-pattern Weston type, and had been found to be correct by comparison with a standard. Five observers were used to obtain the ammeter and voltmeter readings. One called the time every five seconds, two read the instruments, and the other two kept the records. At time of starting the instruments were read oftener than at five-second intervals. A trial trip was made with another battery to get the observers acquainted with their positions, and as the fluctuations in the current were not violent nor many, it is believed that the results represent very nearly the actual facts.

The duration of the stops, and the time the car was in motion between stops, was obtained by means of a stop watch.

The record of speed was obtained by means of a Boyer speed recorder belted, by means of a flexible belt, to the car axle. By means of pressing lightly upon the recording pencil a dot was made in the speed curve every five seconds.

No attempt was made to indicate upon the diagram the ampere or voltmeter readings, as this information is given upon a larger scale in the acceleration tests.

The test may be divided in four parts, as follows:—

——	Distance.	Time.	No. of stops.	Average speed miles per hour.
1. Power house to Blue Island ...	5 9	28:20	12	12·5
2. Blue Island to power house ...	5 9	29:55	19	11·8
3. Power house to Sixty-third Street	5·3	27:40	13	11·5
4. Sixty-third Street to power house	5·3	27:50	13	11·5
Total number of stops ...	...	...	57	

Total time from start, not including stops	...	113:45
Total distance	...	24·40 miles.
Length of one back-up stop, 18 ...	...	·04 „
Total distance travelled	...	22·44 „
Average speed	...	11·84 miles per hour.

In making the stops, an effort was made to approximate actual service and in every way reproduce the conditions of an actual trip. No regular passengers were carried, however, the load consisting of nine observers, the motorman and conductor. The motorman was instructed to follow his usual custom of coasting, where possible. The track was dry for the first two parts of the test, but during the last two parts it was raining, and the tracks were wet. The energy taken from the battery was as follows:—

——	Distance. Miles.	Watt-hours.	Kw.-hours per car mile.
1. Power house to Blue Island ...	5 9	5,533 1	·920
2. Blue Island to power house ...	5·94	5,098	·868
3. Power house to Sixty-third Street	5 3	4,394·6	·820
4. Sixty-third Street to power house	5·3	4,689 6	·885
Total	22 44	19,715·3	·878

It is to be regretted that a profile of the road cannot accompany this report. The road, however, is practically level. The results of the last table would seem to indicate that in general the grade rose from the power house toward the two terminals.

The efficiency of the battery is shown as follows:—

Kilowatt-hours, first charge	36·757
Kilowatt-hours, discharge	19·715
Kilowatt-hours, second charge	31·681
Efficiency (discharge ÷ first charge) ...	53·6 per cent.
Efficiency (discharge ÷ second discharge ...	62·32 per cent.

The graphical log of the two charges were shown, and they differed considerably. This is due to the fact that the charging of the battery was left to the regular operators of the plant, who used their judgment both as to the voltage and as to the time the battery should charge at each voltage. They also determined when the battery was fully charged. In the first charge there is no doubt but that the final voltage was too high, and in the second charge it would seem that the battery was charged too long, both of which conditions reduced the efficiency obtained. The result, however, shows the efficiency in actual service, but does not represent the possibilities of the battery.

The amount of the first charge was, of course, influenced by the immediate previous history of the battery, and for this reason the efficiency obtained by using the second charge as a basis is the more reliable. This test showed that the car used 1·41 kilowatt-hours per car mile, as measured at the charging table, and ·87 kilowatt-hour per car mile was delivered from the batteries to the motor on the car.

Acceleration Tests.

In the tests made upon a car in actual service no opportunity was afforded for actual acceleration tests. These were made November 13th, 1897, upon a straight stretch of track along Vincennes Road, extending south from the power house. In these tests the same instruments and observers as on the other car test were used, and readings were taken in much the same way, with the exception that in this test the observations were made at the time of passing from one point to another of the controller. After the fifth point was reached the readings were taken at 5-second intervals. The time between points was obtained by means of a stop watch, and no effort was made to change the motorman's method of procedure in bringing the car up to speed. The average results of five trials showed clearly the power delivered by the batteries at the different points of the controller and the energy required to accelerate the car.

The current curve showed a maximum of 320 amperes. At this time all four sets of batteries are in parallel, so that this total of 320 amperes indicates a total discharge rate of each cell of but 80 amperes. At the fourth notch it coincides with the total current curve, and at this point indicates the highest discharge rate, which is seen to be 220 amperes, and this rapidly decreases until it reaches 100 amperes, which may be taken as a fair value of the current with the car in full motion. It is to be understood, of course, that the practice of coasting, in which the current is shut off, makes it impossible to obtain the power required per mile from this curve.

In conclusion, it may be said that the foregoing tests do not demonstrate the best results that may be expected of accumulator traction, and were not made for that purpose. No excuse is to be offered for the fact that the road was not operating under ideal conditions while being tested, as the primary object of the test was to determine where improvement could be made. If this is kept in mind when comparing the results with those obtained upon the trolley systems of about the same size, it will be seen that the cost of fuel for accumulator traction, of something less than 1 cent per car mile, is very favourable to storage battery traction. The improvements suggested by the test are now being made. The overhauling of the engines, the repair of the economiser flue, and the securing of a better coal than was used on the test, at a cheaper price, should bring the fuel cost per car mile well within ·5 cent. Figures upon the labour and maintenance factors in the cost per car mile would be of interest in this connection, but are not covered by the figures of the test. The labour account will no doubt be as small as that of any nine-car road, while figures upon maintenance would be premature at this time. The batteries have operated from 8,000 to 14,000 miles, and are standing the service remarkably well, so that the maintenance account, up to the present, has been comparatively small.

THE ECONOMY AND EFFICIENCY OF THE LARGE GAS ENGINE.

Writing to the *Engineering Magazine*, Mr. Dugald Clerk, the well-known gas engine expert, discusses the gas engine in its relation to large powers. We may take it that for small powers the gas engine has, for a long time, been a decided success. It is the only economical prime mover for small powers, and the smaller the power required the more striking has been its success and convenience. As soon, however, as powers are required such that to start the engine is difficult for a man by himself, the inconveniences of the gas engine appear. Until 1890 the gas engine was in a state of development. The Otto patent had given wealth to its owners, and this wealth was used to crush every other patentee who could be brought within striking range. After the expiration of the Otto patent in 1890, the superiority of the Otto cycle was made plain by the abandonment of other cycles of operation and competition in engines really commenced, and competition lead to the attempts at increasing sizes and powers. So far about 200 I.H.P. is the maximum size to which the Otto cycle has been successfully applied.

In 1879 *the* big engine was a 16 H.P.; it held the title for several years. In 1888 the hot tube igniter displaced the old revenue producing slide valve. In 1889 the Simplex engine of Delamere-Deboutteville & Malandin was exhibited at Paris. Its power was 100 H P, and it had an electric igniter and a self starter. Since that time the growth has been to 200 H P. and not a large number of really big engines have been made, the average power of the 5,000 engines built annually in the United Kingdom being 20. The largest engines built by Messrs. Crossley for the Blackpool Tower Company are of two-cylinder type, each cylinder facing its fellow and using the one crank. With coal gas they show 220 H P. The cylinders are 18½ inches diameter and the stroke is 2 feet, the speed being 160. With producer gas they indicate 208 H.P. This engine is really a pair of 100 H P. cylinders on a 200 H.P. crank.

This arrangement, which gives two impulses in a revolution and leaves one revolution with no impulse, has proved better than the side by side cylinder, one crank type which gives one impulse every half revolution. Altogether, Messrs. Crossley have made about 30 engines of over 100 H.P. for various purposes, including the direct driving of dynamos and centrifugal pumps.

Messrs. Tangye have also turned out a considerable number of engines of over 100 H P. and several other makers have made large engines, one by Messrs. Robey & Co. at Messrs. Luke & Spencers, of Broadheath, working on 1⅝ lb. of coke per H.P. hour, including the coke used at night to keep the producer in form, but our author does not consider the total of large engines can exceed 100. As a large engine of 80 H.P. will run for about 1 lb. of anthracite per hour, or of common engine slack, how is it there are not more big engines with such an economy in view for the best steam engines of 80 H.P. would use quite double the above fuel? There are two sets of difficulties, those of the engine and those of the producer; of the first there is the proportion of burned gases left in the compression space—a fault which does not much trouble small engines, whose cooling rate is greater, and the burned-out gases are cooled below the point where they ignite the incoming charge. Some lingering flame remains to ignite the incoming charge in large engines, this ignites the charge in the inlet pipe and the engine loses an explosion. Hence the use of the scavenging charge which Mr. Clerk himself used first. This was in 1881. The Otto engine only adopted scavenging in 1886, and the Griffin engine is well known as having a scavenging stroke, but scavenging was not frequently done until Messrs. Crossley adapted Mr. Atkinson's inertia method. This consists of a long exhaust pipe, the momentum of the discharged gases in which was made to pull a charge of fresh air through the cylinder. Messrs. Wells Bros. had a special annular scavenging cylinder worked as an air pump by the expanded forward part of one piston in their 200 I.H.P. engines of tandem type. Scavenging is admitted to almost completely overcome the difficulty of premature ignition from residual flame, but an engine must be well designed so as to avoid hollow spaces and ports which might not be swept out by the scavenging air. Nor is it to be wondered that there should be premature ignition. With a temperature of 1,800° C. in a compression cylinder and a stroke lasting only one-sixth of a second there is little time for complete combustion. With small engines at even 400 revolutions per minute the ignition is complete, and premature ignition is even difficult to obtain, but large engines are different, having so large a cylinder volume for their capacity or rate of cooling. In many gas engines the initial pressure of compression is nearly 100 lbs. before ignition. In most large engines the terminal temperature exceeds 1,200° C. High compression has reduced this, and enabled more heat to be converted to work, and with scavenging nearly got rid of untimely firing on the charging stroke. But there is still the premature explosion during compression, which is due to the temperature of the high compression, and the piston end of an even well designed piston can hardly be less than a dull red, or, say, 700° C., while the gas must be probably 250° C. when compressed to 100 lbs., so that early ignitions are not to be wondered at. Carbon on the piston and projecting bolt heads are all in favour of causing ignition during compression, and should be avoided. Rich gas mixtures must also be avoided. There is also the risk of a cylinder becoming filled by a mixture of rich gas after several missed explosions. This may be caused by wrong adjustment of the gas and air admissions, and an explosive pressure 30 per cent. in excess of normal may occur. This never takes place with steam engines, and it demands special strength in crank pins, &c., and generally ample margins. Gas engines, therefore, are unduly heavy per H.P. developed, both because of this and because they are only half single-acting. Thus, in spite of all its thermo-dynamic advantages, it has not ousted steam power to the extent which might have been expected. Our author also does not think gas producers are by any means perfect. The Dowson producer requires anthracite at 18s. per ton, so that with a Dowson producer the half weight of fuel used cost more than the double weight of cheaper fuel for the steam engine.

Dowson producers now use coke, but the difficulties with coke are not yet overcome. The Mond producer, according to Mr. Clerk, is the only one making gas fit for use in the gas engine, and this producer is cumbrous and only excellent where ammonia recovery is also carried out. Our author has evidently not seen the Thwaite duplex producer at the works of Mr. Arthur Porritt of Cleckheaton, where, we believe, the cheapest slack is being used and every satisfaction is being given. So far as we can learn, this duplex producer is doing exactly what Mr. Clerk says is required to cause the rapid development of gas power.

A 10 H.P. Crossley engine with 95 lbs. initial compression is showing 22·2 B.H.P., with a consumption of 14·32 cubic feet of Manchester gas per B.H.P. Apply the same economy to large engines and no doubt a B.H.P. hour would be got from 12 cubic feet or 30 per cent. of the heat given to the engine will be returned as work.

In 10 years' time engines of 1,000 H.P. will be as common as those of 100 H P. are to-day. Before applying gas engines to large marine work they must be improved in construction, governing and operation. When the time arrives for this use of gas the equivalent fuel will be easily as low as half a pound per I.H.P. hour.

A good deal of labour has been spent on self-starters. We do not look on self-starters as having a use except between the small engines and those of the maximum size yet made, but are inclined to the view that large gas engines will be started by the intermediation of small engines as with the little so-called barring engines of the textile districts. Undoubtedly there is a future for gas power at sea because of their economy, on land because of the millions of feet of good producer gas sent to waste from every blast furnace.

THE TELEGRAPH TROUBLES.

The Clerks' Point of View.

By CHAS. H. GARLAND.

(*Continued from page* 276.)

There may seem to be a lack of logical arrangement about the order in which the points have been discussed in these papers. This arises to a great extent from the necessities of the case. Such a multiplicity of reasons exists to be discussed that the arrangement has to depend largely on the nature of the evidence rather than on the point contended for. But, undoubtedly, any point which involves a positive wrong, a breach of the promised conditions of service, assumes a greater importance than any claim for an improvement of such conditions. This will explain why the restitution of a scale already conceded was discussed, before dealing with necessary improvements in that scale.

One of the most important improvements asked for has been a better salary after five years' service. "After five years' service" is equivalent to saying at 21 years of age. The average age of entrants into the telegraph service is 16 years; hence, five years later, they enter upon manhood. If it were not for the many objections to an age-scale in the Civil Service, the claim would in all probability have been made for men of 21 years of age instead of "after five years' service." However, the number of entrants under 16 years of age is almost a negligible quantity. The claim, then, is practically a claim for a salary upon which a young man can live, which should be given him at the time he passes from adolescence to manhood. The reasonableness of his claim has been admitted by heads of departments. Thus Mr. H. C. Fischer, C.M.G., Controller of the Central Telegraph Office, in giving evidence before Lord Tweedmouth's Committee on this point, on November 8th, 1895, said: "With regard to the five years' service men, I am of opinion that they are underpaid at that period. The commercial value of the service they perform at that time is much higher than the wages they receive." "I have always held that telegraphists are not getting sufficient at that time. They scarcely get sufficient to keep themselves, and yet are, as a rule, rendering very efficient service." Asked how much the salary should be increased, Mr. Fischer suggested £10 or £12 per year, adding that less would be insufficient. This is a most pathetic picture. The head of a large State monopoly confessing that despite, or perhaps because of, the postal profit of three to four millions per year, a number of its young servants do not receive enough salary to keep themselves.

It is proverbially difficult to reach the heart and conscience of a corporate body, but surely we have here a thing that should touch the individual hearts of even so impersonal a corporation as "the Department," or, if need be, that mysterious and callous entity, the Treasury.

Mr. Fischer was not alone in his view. Support was given by other officials, and from the most unlikely quarters. Mr. J. C. Badcock, Controller of the London Postal Service, on November 11th, 1895, when giving evidence before the same committee, said: "I think the pay in the lower stages is somewhat inadequate." "There should be a material increase after five years' service." Mr. W. H. Preece, F.R.S., said: "I have no doubt that a clerk of five years' service under the present scale does not acquire sufficient to keep himself in a proper position." Even Mr. Lewin Hill, with all his dislike to generous scales for the minor establishment, provided for an increase after five years' service in the proposed revision he submitted to Lord Tweedmouth. When the reasons for an increase at a certain point are so strong as to convince the heads of departments that a readjustment is necessary, it is a fair assumption that overwhelming evidence must exist in its favour. Yet nothing, or practically nothing, has been done. Under Mr. Raikes's revision a clerk got £63 after five years' service; under the present system he receives £64. So, in the face of all the evidence of the necessity for a "material increase," which Mr. Fischer thought should be £10 or £12 a year, he receives the munificent sum of £1, or 4½d. weekly! Really, one is inclined almost to agree with the view expressed by Mr. H. M. Hyndman, in the January *Cosmopolis*: "The Post Office .... employs men and women in vast numbers, with as little regard for their general well-being as if the State were itself a greedy private employer or an unscrupulous limited company."

But it were unfair not to state here that in order to encourage a knowledge of both postal and sorting duties and the acquirement of technical knowledge, an extra increment of £6 is offered to all those clerks who pass an examination in sorting duties, and a further £6 for passing an examination in technical telegraphy, telephony, and in magnetism and electricity, such double increments not to affect the maximum of the scale. This latter condition means that technical knowledge is of no value in a man at his maximum, although it be valued at £6 annually in a man lower down the scale. For telegraphists at the Central Telegraph Office the sorting increment is a dead letter. Of 18 men who have attempted to obtain it—a sufficiently small proportion of 2,000—all have discarded the attempt because of the difficulties attendant upon it. The other increment for technical work is being taken up.

That such encouragement—small as it is—should be given for the acquirement of technical knowledge is a matter for rejoicing, but that it should be regarded as in any way meeting the difficulty of inadequate pay, is food for many reflections. The pay after five years is inadequate, it does not pay the men the commercial value of their services; but before giving any relief the Department exacts further services—further qualifications. The pay is at least £10 or £12 per year less than the value of the work already performed, and yet you must give us more and better work before we increase it by £6. So, in effect, says the Department. A body of young men who are admittedly receiving "scarcely sufficient to keep themselves," are taxed in class fees, cost of books and time, before they receive a very inadequate measure of relief. Telegraph clerks are as little inclined as others to look a gift-horse in the mouth, but when, after praying for years for necessary bread they are offered a stone, can it be wondered at that they grumble? So the underpaid five years' man it still discontented.

There are many other points in connection with the salaries of telegraph clerks which are anomalous and unjust, but a volume could be filled with an exhaustive exposition of them. These papers will only deal with some of the main points, and constitute a summary. But they will be a summary which will throw a light on methods and principles which should have no place in a State Department. The scales asked for by the Postal Telegraph Clerks' Association, as a means of settling the whole matter, are moderate, and meet all the difficulties. Before passing to the question of annual leave, which is a vital question with the men, a quotation from a letter by the genial, but just Mr. A. Birrell, Q.C., M.P., will, I hope, justify itself. "What is the duty of a State Department to its servants?" he asks: "That telegraph servants are cruelly underpaid is certain; on the other hand, such is the state of trade, and so overcrowded are the markets, that there would be no difficulties in filling the places of any of the servants of the Department who chose to vacate them. The taxpayer is the ultimate employer in this case. Is it fair to him to make him pay fancy wages? This much is clear—that a public establishment which brings in a revenue, ought to treat its workmen as generously as the highest class of private employer; a wealthy man who sweats a poor man is admittedly a rascal. If the State cannot afford to run the telegraphic system, except by underpaying its servants, let it give the business up. All public departments are sickening institutions, and nobody can contemplate the State becoming the universal employer without dismay, except by assuming that in future public departments will be totally unlike what they are and always have been."

The question of annual leave is one which causes much bitterness of feeling among the staff. What is the object of annual leave? To be a rest from the work and worry of the office, from the stress and turmoil of the City. The majority of the readers of the Electrical Review look forward to their annual holiday, I am certain, as a period of happiness and sunshine, of rest and quiet. In one's mind the prospect of annual leave is always pictured on a background of hill and dale, green meadows, or foam-flecked sea. The days are long spells of light, of sunshine, and the nights are canopied with a vault of spangled, deep-hued blue. So should a holiday be. But what is the background of the underpaid telegraph clerk's holiday? Mist, fog, rain, sleet, and all the wintry grime of a city's streets. No sunshine at home, nothing but a leaden sky, and no money with which to fly to the South of France in search of warmth and light. Year after year the young men of the telegraph service take their holidays in winter, and year after year they will continue to do so unless some radical change be effected. The periods are chosen by seniority, and are spread equally over the whole year. So one-twelfth of the staff goes in November, one-twelfth in December, one-twelfth in January, and one-twelfth in February. And the same unfortunates continue to be relegated to these months year after year.

Sir Albert K. Rollit said at the Treasury Conference last year: "No matter what class a person may be in, the public are dependent upon skilled labour, and the staff should not be compelled to take its holiday during the winter, whatever the alternative may cost, so long as there is a balance of revenue." He further declared, when the female representative was under examination, "I think it is revolting to hear a young person such as that say she is never to have a summer holiday. It cannot be to the interest of the individual or the State." Mr. Hudson Kearley, M.P., himself a large employer of labour, on the same occasion, said: "There is no other service in the country—public or private—where holidays have always to be taken in the winter. No railway company and no private employer imposes such a condition." Lord Tweedmouth's Committee in their report, said: "We think that the request that the annual leave should be granted in the better months of the year is natural, and are agreed that whenever the conditions of service will permit, every endeavour should be made to meet it." The Duke of Norfolk and Mr. Hanbury promised, after the Conference at the House of Commons, that an attempt should be made to devise means of improvement. And on this promise the telegraph service relied, with the result that the holidays at the Central Telegraph Office are based upon the same principle this year as last. What is the real difficulty in the way of granting this natural request. The Controller or the Central Telegraph Office should know, at least so far as his own office is concerned. The following abstract from his evidence before the Tweedmouth Committee is therefore conclusive.

4,064. The CHAIRMAN: Is it not practicable to confine the holiday period to the eight months of the year?—It is a question of expense.

Later on, following leading questions from his chief, Sir S. Walpole, he added other reasons; but to anyone who understands the ordinary human being, no comment is needed. Undoubtedly the question of expense is the stumbling block in the way of deleting the four months, January, February, November and December from the holiday sheets. Yet the Duke of Norfolk and the secretary to the Treasury have pledged their personal words to devise some improvement. Are telegraph clerks unreasonable in asking that some of the annual profit of four millions should be spent by the Postmaster-General in redeeming his word of honour? In Germany, where the conditions of pressure are the same as in England, the additional expense is incurred, and the summer months are the holiday months. And even in other branches of the English postal service the holidays are confined to the eight best months. Up to now, no hint has reached us, that the Postmaster-General and his immediate staff ever take their annual leave in winter, whatever the conditions of work or expense.

(*To be concluded.*)

STORAGE BATTERY TESTING AT HIGH DISCHARGE RATES.

By RANKIN KENNEDY.

It is well known that in all storage cells in which solid active materials are used the capacity falls rapidly as the rate of discharge is increased. Without entering into the cause of this peculiar phenomena we can endeavour to ascertain the amount of drop in various cells as we increase the discharge rate.

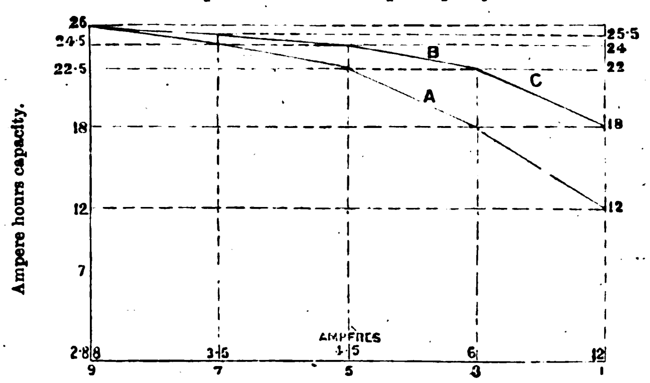
Some of the drop is due to internal resistance of the electrolyte, this can be measured by the difference in terminal pressure with and without the current flowing, but the greatest fraction of the drop is due to something more than internal resistance, and this something varies in value in different cells.

For traction purposes cells are tested for watt-hours per lb. gross weight, spread over a time of from 5 to 8 hours' discharge, but for lighting purposes the gross weight of the cell is of minor importance, while the drop in capacity as the discharge rate increases is of very great importance. Cells at central stations may be called upon to deliver their full discharge in 1 or 2 hours, hence the cells which give the greatest capacity at highest rates are best for that purpose.

If we take two cells of different makes, we will find that if the cells are made for the same discharge rate and capacity on a fairly long discharge, or that at low rates they are practically equal, say, that at 2·88 amperes the capacity for both comes out 26 ampere-hours on a 9-hours' run; if we now discharge them at 3·5 amperes we find cell A finishes in 7 hours with a capacity of 24·5. Cell C in same time has not run down but gives 25·5 capacity, and so on we can obtain readings which, when plotted out as in diagram, give curves, showing that although the cells are equal in capacity at the low 9 hours' discharge, that they are not equal at the higher rates, C being by far the better cell.

The curve, A, is one found by actual tests. The figure 1 on horizontal is cut by an ordinate passing through 12 and 18, showing that cell A discharged in one hour, gave a

Comparative curves for drop in capac'ty.



Hours in which cell is completely discharged.

capacity of 12, while C, discharged at same rate, gave 18, that is, at 12 amperes A discharged in one hour while C ran on for 1·5 hours. A is here taken as a standard for comparison.

On the 3 hours' discharge at 6 amperes, cell A gives 18 ampere-hours, cell C gives 22, and so on, the difference diminishing as the rate diminishes.

That cells can be improved in this direction is clear by one example. Thus the E.P.S. central station cell, K-type, is made for 310 amperes rate discharge in 7 hours; at this rate it gives a capacity of 2,170 ampere-hours, but discharged in 1 hour it gives only 1,050 ampere-hours' capacity, while their improved F.K. cell for same capacity at the low 7 hours' rate of discharge, now gives 1,230 ampere-hours' capacity in a 1 hour discharge—a very well marked improvement. In this comparison we take two cells equal at the 7 hours' discharge, and find that they are to each other on a 1 hour discharge as 10·5 is to 12·3.

For all practical purposes cells for rapid discharges may be compared in this way by making two tests only; one at a 6 or 7 hours' run, or any other time at which the cells to be compared are equal or nearly equal in capacity, then make another test at a rate to discharge the cells in one hour, the difference in capacity between the two cells at the higher rate indicates the difference in efficiency between the two cells. Thus, to take the above example :—

$$\text{This efficiency is equal to the } \frac{\text{ampere-hours at high rate}}{\text{ampere-hours at low rate}}$$

With a perfect cell it would be unity.

In the above example the discharge of K cell at low rate is 2,170, and at high rate 1,050, therefore efficiency is

$$\frac{1{,}050}{2{,}170} = 0{\cdot}484, \text{ the F.K. cell } \frac{1{,}230}{2{,}170} = 0{\cdot}567.$$

The figures are not the gross efficiency given by watt-hours put into cell and watt-hours given out by cell, but are comparative values indicating the drop in output as the rate of working increases.

It would be instructive and interesting if the data were available to compare these curves for a cell of the strip type like Blot's, with a cell of grid type. Theoretically the curve should be better in cells where the active material is spread thinly over large surface.

Whether this is borne out in practice cannot be proved by the author owing to the absence of data.

In this way the all-round performance of any cells can be indicated, even for traction cells it is the best test between two cells of nearly same watt-hours per lb. at the long discharge.

Some such test is necessary, for traction cells have to work at all rates of discharge, so that to arrive at an approximate idea or value of the cells under working conditions the two tests are required to fairly compare two cells.

Of course, this is a supplementary test in the case of traction cells, and whatever the cells may be which are to be compared they must give same capacity in the 6, 7, 8, or 9 hours chosen as the low rate time. Two cells may give same capacity at low rates, and if their watt-hours' capacity per lb. is equal, or nearly so, at that rate, it is clear the watt-hours' per lb. of the cell which has highest capacity at the high rates will have the highest value in actual work on a variable load.

Only in the impossible case of a cell with no drop in capacity on an increasing load is the test of capacity, at one or two low rates, any reliable index of the capacity under the varying rates found in practice.

It has hitherto been too readily assumed that if a cell is superior to another at one or two rates of discharge it is therefore superior all along the line.

In concluding these occasional articles on battery testing, it may be pointed out that while actual testing and noting down results is a simple matter quite within the capacity of a student at school, the laying out of the plan of the tests and the making of comparisons between the results observed and other results already published, is a task which presents some difficulties to those who are considered capable experts.

We have well known accepted methods for comparing engines, dynamos, motors, transformers, lamps and other appliances, but it seems we have no recognised methods for testing and reporting upon storage batteries in such a way that the results are comparable and above suspicion of errors.

REVIEWS.

The Law and Practice of Letters Patents for Inventions. By Lewis Edmunds, D.Sc., Q.C. Second Edition by T. M. Stevens, D.C.L. London: Stevens & Sons, Limited, 119 and 120, Chancery Lane. Price 32s.

The annual number of patents granted to inventors appears to be one of the best indications of the manufacturing activity of a country. At least, the United States, Great Britain, and Germany stand at the head of the list in both these respects. Probably the greatest number of inventions per annum are patented in this country, but though there may be some doubt whether we or the U.S.A. stand first in numbers, there can be no doubt that the patent law of this country is the oldest in the world.

We learn from the interesting history of Patent Law in Dr. Edmunds's volume that the grant of Letters Patent conferring a monopoly is one of the last survivals of the once extensive prerogative of the Crown. As late as the reigns of Edward III. and Richard II. the king claimed to give special privileges to individual traders, but the first patent for an invention in the modern sense appears to have been granted in the reign of Henry VI. to two aldermen "that they and their assignees should have the sole making of the philosopher's stone." Up to the time of Elizabeth patents were granted for new inventions, and also for restraint of trade in articles or arts already known. The latter class of monopolies were after a long struggle during the reigns of Elizabeth and James I. declared to be illegal, and the prerogative of the Crown was restricted to granting patents for new inventions only.

In 1624 the Statute of Monopolies was enacted, and it is on Section 6 of this Act that Letters Patent for invention depend. The present term of 14 years was then fixed, and the patent was to be granted to the true and first inventor only. The procedure for taking out Letters patent was subsequently modified by Acts passed in 1852 and 1883 and amending Acts in 1885, 1886, and 1888. Some idea of the long and cumbrous procedure necessary to obtain a patent before 1852 may be obtained, when we learn that the applicant had to make application at least 10 separate and distinct times to almost as many different officials. The Home Secretary, the law officers, the Lord Chancellor, all had a finger in the pie, and the wonder is invention was not strangled with red tape. Happily our Patent Law has now been simplified, and the cost of obtaining a patent reduced to a very moderate amount. Our patent system is still behind those of its leading modern rivals in one respect; it takes no steps to ascertain that patents are granted for new inventions only. The United States has examined inventions for novelty for the last 60 years, and the leading European countries, with the exception of France and Great Britain, have also adopted the American system.

Our patent practice has been otherwise brought, by a long series of legal decisions, to a state of great perfection, and in no treatise will a better exposition of Patent Law and Practice be found than in Dr. Edmunds's volume. The present edition extends to almost 1,000 pages, and appears to contain sufficient information to start a patent barrister or a patent agent in business in a small way. The subject matter of the volume is well arranged and indexed. It is divided into two parts; Part I. discussing Patent Law and Practice, and Part II. containing the Patent Acts at present in force, with full and valuable notes. Wherever we have tested the matter in this huge volume, we have found it reliable, accurate, and up to date; the style and arrangement is so clear, that a consulting engineer, or even a patentee without legal training might, in many cases, settle points in dispute about patent rights, and save the parties concerned from expending thousands of pounds on patent litigation.

Glass Blowing and Working. By T. Bolas, F.C.S., F.T.C. London: Dawbarn & Ward, Limited, 6, Farringdon Avenue, E.C.

The author, at the commencement of his book, points out that glass blowing is an interesting recreation as well as an industry, although very few people seem to recognise this. As cultivating delicacy of touch and perception, Mr. Bolas says it stands almost alone, though this is probably an exaggeration which an enthusiast always credits to the art in which he is particularly interested. A few pages which are devoted to the historical aspect of glass are decidedly interesting. Careful details are first given as to the best standard form of blowpipe; also various forms of bellows are described, and it is even shown how two pairs of ordinary domestic bellows may be adapted for blowpipes. The various tools required are next described in detail; in fact, attention to detail is a characteristic of the book. The working of glass for all kinds of philosophical instruments is fully gone into, so that the whole work makes an excellent treatise which can be highly recommended.

Journal of the Institution of Electrical Engineers, No. 131. London: E. & F. N. Spon, 125, Strand.

The general contents of this number are as follows:—"Accumulator Traction on Rails and Ordinary Roads," by L. Epstein.

The Workmen's Compensation Act, 1897. By W. A. Willis, LL.B. Third edition. London: Butterworth & Shaw and Sons, 1898.

This third edition of a really important little book has been revised and somewhat extended. We doubt if employers generally have given to the Act of 1897 that consideration which it deserves. They will find in the very near future that they have made a mistake by not so doing. The Act was that of a Conservative government, and probably had such an Act been brought into being by a Liberal or a Radical government there would have been such a terrific outcry through the length and breadth of the land, that all England would have been roused to a full and proper sense of the ruin of the constitution and the dangers of socialism, and all that sort of thing which is allowed to pass for statesmanship when hall-marked by the Tories. The new appendix consists of a form of application for certificate to scheme issued by Chief Registrar where employers and employed alike agree to a contracting out scheme. The Act itself is remarkable as the first instance in the history of English Jurisprudence, wherein a liability has been cast upon an individual to pay damages for injuries which are not the result of any negligence or other unlawful act either of himself or his servants, for whose conduct he is legally responsible.

An employer by this new Act is practically made to compulsorily insure his workmen, or failing to do so, he is liable for all or any of their injuries, to the extent of bankruptcy. Under common law an employers' liability has three limits, known as the doctrine of common employment, accepted risks, and contributory negligence. The Act of 1880 was intended to destroy the first limitation. This Act left the door open for much evasion of its provisions and for much litigation. Mr. Asquith's Bill of 1893 was introduced to meet these objections, but was withdrawn because of the insistence upon contracting out by the Lords. By the Act of 1897 one limitation alone seems to be preserved, where a man's serious and wilful misconduct shuts him out of any compensation. What a field is here for litigation ! ! Serious and wilful misconduct ! ! ! Who is to be the judge ? Contracting out is limited to where a scheme has been formulated and certified by the Registrar of Friendly Societies as conferring benefits equal to the Statute. An employer cannot evade liability by sub-contracting. Perhaps this may help to wipe out the ridiculous objection to sub-contracting by London vestries and other bodies.

Speaking generally, however, the employers' lot is not a happy one. If he cannot be got at under the new Act the Act of 1880 may be brought to bear on him, and failing that the common law is still a weapon in the hands of his enemy. Then there is a Fatal Accidents' Act of 1846. The employers only chance, if he be a small employer, is to insure against all liability; if he be a large employer he may join his workmen in a scheme of contracting out. We would advise all employers to buy and read this book, and study its very stringent clauses. We are not quite sure if an employer would not be liable if one of his late workmen out on strike got hurt while on picketting duty.

General Elementary Science. Edited by WILLIAM BRIGGS, M.A., F.C.S., F.R.A.S. London: W. B. Clive, University Correspondence College Press.

We have received from the University Correspondence Press a copy of another edition to the long list of books that have appeared in recent years for the use of science students. This work, written by four authors of considerable reputation, under the editorship of Mr. William Briggs, covers the general ground of elementary mechanics, physics, and chemistry, and is particularly designed for the Matriculation Examination of the University of London. It is arranged in a series of more or less disconnected paragraphs, as, indeed, many successful educational books have been, from Euclid and Routh's Rigid Dynamics, downwards. Regarded as a cram book, *i.e.*, a book arranged with the definite purpose of preparing candidates for examination, we do not see how it could well be improved. The arrangement of the propositions is logical and consecutive, the explanations are simple and exact; where a complete definition may be beyond the students' comprehension, *e.g.*, in that of electrical potential, a note is added; the illustrations seem sufficient for the purpose. Every page contains evidence of the intellect required for the production of a good elementary book. The volume is of a convenient size for the pocket, and the typography is excellent.

NEW PATENTS.—1898.

[*Compiled expressly for this journal by* W. P. THOMPSON & Co., *Electrical Patent Agents*, 322, *High Holborn, London, W C., to whom all inquiries should be addressed.*]

4,879. "An improved method of distribution of news and music by telephone." L. E. WILSON. Dated February 28th.

4,895. "Improved manufacture of insulating conduits for electrical conductors and appliances employed in connection therewith, and for laying the conductors therein." F. T. WOODCOCK. Dated February 28th.

4,900. "Improvements relating to joints of telegraph wires." A. A. COMMON. Dated February 28th.

4,903. "Improvements in primary batteries." J. E. FULLER. Dated February 28th. (*Complete.*)

4,910. "Improvements in, and relating to, primary batteries." C. KOENIG. Dated February 28th. (*Complete.*)

4,926. "Improvements in, and relating to, portable electric lamps and batteries therefor, and for other purposes." H. H. LAKE. (L. Paget, United States.) Dated February 28th.

4,929. "Improvements in, or relating to, electric railway conduits and conductors." A. J. BOULT. (R. Snyers, Belgium.) Dated February 28th. (*Complete.*)

4,995. "Improvements in electro-magnets or magnetic closers for use on electric railway vehicles." J. N. THOMAS. Dated March 1st. (*Complete.*)

4,999. "Improvements in, and relating to, electric railways." W. M. BROWN. Dated March 1st. (*Complete.*)

5,001. "Improved controlling system for electric railway vehicles." S. H. SHORT. Dated March 1st. (*Complete.*)

5,029. "Improvements in regulating apparatus for arc lamps." H. LEITNER. Dated March 1st.

5,034. "Improvements in, or relating to, electrolytic electrical meters." C. O. BASTIAN. Dated March 1st.

5,048. "Improvements in electric meters." EVERSHED & VIGNOLES, LIMITED, and S. EVERSHED. Dated March 1st.

5,049. "Improvements in alternating current motors." W. STANLEY. Dated March 1st. (*Complete.*)

5,054. "Improvements in current collectors for dynamo-electric machines." G. W. NELL. Dated March 1st. (*Complete.*)

5,062. "Improvements in incandescent electric lamps." W. P. THOMPSON. (J. T. Lister and W. S. Chamberlain, United States.) Dated March 1st. (*Complete.*)

5,064. "Improvements in non-synchronous electric motors." R. BELFIELD. (B. G. Lamme, United States.) Dated March 1st.

5,065. "Improvements in arc lamps." R. BELFIELD. (H. P. Davis and F. Conrad, United States.) Dated March 1st.

5,066. "Improvements in electric switches." R. BELFIELD. (H. P. Davis and E. F. Harder, United States.) Dated March 1st.

5,067. "An improved means for feeding the carbons in electric arc lamps." C. WOOD. Dated March 1st.

5,068. "Improvements in and relating to the carbon-feeding mechanism of electric arc lamps." C. WOOD. Dated March 1st.

5,083. "An improved means of and apparatus for varying the strength of electrical currents." R. HOPE-JONES. Dated March 2nd.

5,130. "Method of utilising the interior of electric incandescent lamps for advertising purposes." L. BISHOP. Dated March 2nd.

5,133. "Improvements in electric lamp fittings." J. M. HUSMAN and H. C. GOVER. Dated March 2nd.

5,162. "Improvements in the manufacture of waterproofing coating compositions for wearing apparel, covers, engine and other packings, acid tank linings, electrical insulating compositions, and for other uses." C. J. GRIST. Dated March 2nd.

5,172. "Improvements in telephone transmitters." J. V. COLLINGWOOD. Dated March 2nd.

5,176. "Improvements in means or apparatus for starting and regulating electric motors." J. H. HOLMES. Dated March 2nd.

5,177. "Improvements in dynamo-electric machines." W. B. SAYERS and MAVOR & COULSON, LIMITED. Dated March 2nd.

5,178. "Improvements in the manufacture of electrical transformers, and other alternating current apparatus having iron cores." A. F. BERRY. Dated March 2nd.

5,185. "Improvements in electrical conducting apparatus for tramways, railways and the like." C. F. P. STENDEBACH. Dated March 2nd. (*Complete.*)

5,186. "Improvements in or relating to secondary batteries." R. HADDAN. (H. Dolter, France.) Dated March 2nd. (*Complete.*)

5,208. "Improvements in electrically operated gas valves for burners." THE ACTIENGESELLSCHAFT FUR FABRIKATION VON BRONCEWAAREN UND ZINKGUSS VORM., J. C. SPINN & SOHN and S. J. VON ROMOCKI. Dated March 3rd.

5,260. "An improved primary battery." E. A. MITCHELL. Dated March 3rd.

5,287. "Improved coin feed mechanism for making and breaking electrical contacts." R. HADDAN. (M. Vidal, France.) Dated March 3rd.

5,288. "Improvements in globes or bulbs for electric incandescent lamps for decorative advertising and other purposes." P. HERBE. Dated March 3rd.

5,300. "Improved means for lighting railway trains electrically." R. R. MEACOCK and A. J. HARPER. Dated March 4th.

5,343. "Improvements in fluids for impregnating bodies or suitable fabrics, threads, fibres, or the like, for incandescent lighting purposes." F. P. FOSTER and G. (BODO) PUCHMULLER. Dated March 4th.

5,379. "Improvements in the manufacture of deep sea telegraph and telephone cables." W. T. HENLEY'S TELEGRAPH WORKS COMPANY, LIMITED, and G. SUTTON. Dated March 4th.

5,418. "Improvements in electric telephony." C. ADAMS-RANDALL. Dated March 5th.

5,423. "An automatic electric switch for hoists and cranes." J. GODDARD. Dated March 5th.

THE

ELECTRICAL REVIEW.

VOL. XLII. MARCH 25, 1898. No. 1,061.

CONTENTS:

THE ELECTRICAL REVIEW.

Published every FRIDAY, Price 4d.

The Oldest Weekly Electrical Paper. Established 1872.

TO BE OBTAINED BY ORDER FROM ANY NEWSAGENT IN TOWN OR COUNTRY.

OFFICE:—4 LUDGATE HILL, LONDON.

Telegraphic Address: "Aherkay, London." Code A B C.

Telephone No. 988 Holborn.

ALL Letters should be addressed to the Proprietors, H. Alabaster, Gatehouse & Co.

ADVERTISEMENT RATES ON APPLICATION.

The "Electrical Review" is the recognised medium of the Electrical Trades.

SUBSCRIPTION RATES.—In *Great Britain*, Post Free per Year, 19s. 6d. To *all other countries*, per Year, £1 4s.

BINDING.—Subscribers' numbers bound, including case, for 4s. each volume.

CASES.—Cloth Cases for Binding can be had, price 2s. 6d. each.

READING CASES, to hold from One to Twenty-six Numbers until the Volume is complete for Binding, can now be had from the Publishers, Price 6s. or Free by Post (in Great Britain), 6s. 6d.

FOREIGN AGENTS.—*New York:* D. Van Nostrand, 23, Murray Street. *Paris:* Veuve J. Boyveau, 22, Rue de la Banque. *Berlin:* Asher & Co., 5, Unter den Linden.

Cheques and Postal Orders (on Chief Office, London) to be made payable to Mr. H. Alabaster, 4 Ludgate Hill E.C.

ELECTRIC POWER SUPPLY FROM CENTRAL STATIONS.

NOTWITHSTANDING the enormous progress that has been made in this country in the last half-century in perfecting and cheapening our methods of production, and of transporting the raw material to, and the finished article from, the manufacturer, we find that other nations have advanced as fast or faster than ourselves, and that our manufacturing supremacy is no longer so marked as in past times. The causes of this increased competition are many and various, and if we wish to maintain our position in the front, we must take care to make the most of such advantages as we possess; employers must not be slow to adopt labour-saving appliances, nor to replace existing tools by others of improved design and greater possible output; the management must keep a sharp look out for, and at once remove, all possible causes of waste; and the workman must realise that his chance of increasing his weekly earnings lies in doing his best to increase the output of the machinery he tends.

We have been accustomed to think that our coal fields and railways give us an advantage over our rivals; but this is not always so, as there are cases where transport freights are lower in other countries than with us, and the introduction of electric transmission of power has made it possible in some districts to do without coal, and to utilise the energy of falling water. The fact that in our manufacturing districts coal is cheap, and that in many cases the cost of power is only a small item of the total cost of production, has made many of our manufacturers somewhat neglectful of this branch of their operations; and we too often see boilers, worked at ridiculously low pressures, supplying steam through long ranges of pipes to small and uneconomical engines, or engines transmitting power through such an amount of shafting, gearing, and belting, as to leave but a small percentage of the power produced available at the machines.

The importance of keeping down the cost of power is beginning to be more fully recognised, and already a certain number of works have electric generating stations whence power is transmitted electrically to motor-driven machinery with a gain in economy over the older methods; and it is now proposed by the Midland Electric Corporation for Power Distribution to go a step further, and to put down a central station for the purpose of electric power supply over an extended area. The paper by Mr. Addenbrooke, "Electric Power Supply from Central Stations," which was read a fortnight ago before the South Staffordshire Institute of Iron and Steel Works' Managers, deals with this question of cost of power; and, after some remarks on the cost of water-power as compared with that of power produced by coal, gives an outline of the Midland Electric Corporation's scheme as an example of the best way of getting the power from the coal to the machinery it is to drive.

The comparison of cost of power obtained from water or coal is disappointing, as the paper gives nothing but general and somewhat vague expressions of opinion, arriving at the conclusion that the difference in annual cost between water and steam power is practically the cost of coal and stoking or handling it; and that "the whole of this difference can only be debited against the coal power on the assumption that no rent is paid for the water-power, nor any inordinate sums for its conservation and utilisation." The subject is a difficult one, and the paper before us does not add much, if anything, to our knowledge of it; as we cannot consider any arguments of much value which are unsupported by figures of the capital cost of existing water-power installations. Mr. Addenbrooke says that the cost of buildings, dynamos, switch gear, motors and mains, will be the same in both cases, except that, as regards the mains, water-power will generally be at some disadvantage, because large waterfalls are often not very accessible. It appears to us that this point may be of considerable importance, as either the distance that power has to be transmitted will be very much greater, or, if works are erected near the water-power, the cost of transport of material to and from the works will be increased. It must not, however, be forgotten that this very inaccessibility of the water-power often permits of the use of bare overhead wires, and a cheaper line construction than would be possible in South Staffordshire or other districts equally well placed as regards cost of coal.

We are next told that we shall not be far out if we put the cost of turbines, turbine pits, sluice gates, and general arrangements against that of steam engines of similar power, but no figures are given; indeed, the only figure of capital cost given in this part of the paper is that the cost of boiler plant, with condensers and economisers, will be about £4 per horse-power, and we are asked if the necessary canals, tunnels, embankments, weirs, or dams could be constructed for the same figure. But this is just the question we would ask the author of the paper; as, unfortunately, English engineers have little chance of gaining personal experience in such work, although they would have no difficulty in fixing the cost of a boiler plant of any given size. It would, therefore, have been much more satisfactory if Mr. Addenbrooke had been able to tell us the capital cost of various water-power installations, even if he had left us to supply the figures for steam power.

With regard to working expenses and general charges, we are told that whilst the depreciation on buildings, dynamos, switch gear, motors, and mains will be the same in each case, on boilers and engines it will probably be greater than on turbines, canals, and other constructional work, and that the cost of administration, of engineering staff, and of rates, taxes, and other standing charges, will probably be the same. By balancing the greater depreciation on steam plant against the probable greater capital cost of water plant, Mr. Addenbrooke arrives at the conclusion that the cost of coal and stoking is the only unbalanced item, and proceeds to calculate this cost per I.H.P. per annum. The figure arrived at, viz., £2 10s. per I.H.P. for a working year of 8,000 hours, is quite possible of attainment with a good load factor; but if steam-power had to compete against water-power with that extra charge against the former, it would be a serious handicap in an industry where power is used continuously, and where its cost forms a large proportion of the total cost of production. A working year of 8,000 hours is not, however, the normal thing in England, the usual conditions being a 54-hour week, or, say, 2,800 hours per annum, and Mr. Addenbrooke argues that, under these conditions, coal can compete better with water, because the extra charge will be reduced from £2 10s. to 17s. 6d. per annum. This is, of course, true, if the comparison is restricted to one between coal and water, with the same load factor and hours of working; but the statement must not be taken to mean that there is any economy in short hours, as owing to the cost of coal being, in the majority of our manufactures, a comparatively small item in the total cost of production, a steam factory working 10 hours per day may easily produce cheaper than a rival water-power factory, if this latter works only nine hours per day. The load factor is the important item, and we do not think that Mr. Addenbrooke has allowed sufficiently for it in fixing the cost of coal for the smaller number of working hours; as, although the bulk of the demand for power may come between the hours, say, of 6 a.m and 5 p.m., there will always be some demand outside these hours, and the cost of coal per horse-power-hour will undoubtedly be increased by the smaller load factor, and by the stand-by losses.

With regard to the proposals of the Midland Electric Corporation, the paper does not tell us much that has not already been made public, as the system to be employed, whether direct current, two-phase, or three-phase, remains still undecided; but we learn that current will probably be transmitted at 5,000 volts pressure, and some figures are given of the cost of the primary mains. Considerable attention has been given to the method of charging for the electricity, and it has been decided to charge on the Demand meter system, the rates for power supply having been fixed in the agreements with certain local authorities at 3d. per unit for the first hour's use per diem taken on the maximum demand, and ·825d. for each subsequent hour. A table is given in the paper which shows the average price per unit for any number of hours of maximum demand per diem, from which we see that for most manufacturing establishments the average charge per unit would be about 1¼d. At this price it would certainly pay all small power users to take current from the Corporation rather than to generate it with their own plant, but there is no reason why users of 50 horse-power or even less should not be able to generate electricity on their own premises at the same or a lower cost.

Let us consider a case where there are 312 working days of nine hours each per annum, and where the average load is half the maximum. The average charge made by the Midland Electric Corporation would then be 1·3d. per unit., and the charge per kilowatt for the year would be £15 4s. 2d., of which, taking Mr. Addenbrooke's figures, only about 27s. 6d. would represent the cost of coal and stoking at the central station. Of course in an isolated plant the consumption of coal will be much greater, but there should be no difficulty in obtaining boiler, engine, dynamo, and piping for a 50 kilowatt plant at the rate of £25 per kilowatt, and producing the kilowatt-hour for a consumption of 10 lbs. of coal with a load factor of 50 per cent., all stand-by losses included. One man, with occasional extra help for boiler cleaning or other extra work, could look after this plant, and an allowance of £100 per annum for labour will therefore be sufficient. The average output being 25 kilowatts for 2,808 hours, the output in the year will amount to 70,200 units, and the cost of labour will therefore be ·342d. per unit. Taking coal at 5s. per ton, the figure given by Mr. Addenbrooke for the neighbourhood of South Staffordshire, we see that coal will cost $\frac{10 \times 60}{2,240} = \cdot 268$d. per unit, and if we add ·05d. per unit for oil and waste we get for material and labour a cost of ·660d. per unit, leaving a margin of ·640d. per unit for interest, depreciation, and repairs, to make up the cost of 1·3d. per unit which would be charged for a supply from the central station. As the output is 70,200 units per annum, this represents a sum of £187 4s., or practically 15 per cent. on the £1,250 which we have taken as the cost of the 50-kilowatt plant.

It would appear, then, that there is no need for manufacturers to wait for a central station supply to realise the economy in the cost of power which is offered by Mr. Addenbrooke, except for the saving in capital expenditure. This is, to many of them, a very important point, and the fact that no money will have to be spent on generating plant, and that it will be possible to hire motors from the Midland Electric Corporation should be a great inducement to the introduction of electric power by many who hesitate about making the change on account of the considerable capital expenditure involved.

Water Power for Crieff.

THERE is a water power scheme in the air at Crieff, the source of power being the falls of the Turret, which are on the estate of Sir Patrick Keith Murray, who offered to give the falls for power purposes and had measurements taken which he submitted, says the *Scotsman*, to a London electrician. This gentleman said the falls were not sufficient for the purpose. Mr. Arnot, of Glasgow, had also reported unfavourably of the falls as insufficient to light the town of Crieff. Sir Patrick intimated the London decision to the town in order to save them further trouble and expense. Mr. R. F. Yorke also furnished the Town Council with a report, and he writes to the *Scotsman* to say that no other electrician but himself has been consulted, but that a turbine manufacturer to whom wrong data were submitted stated the power as insufficient. Mr. Yorke writes he has since further explained matters to Sir Patrick, and that the fall is of 300 cubic feet of water per minute through a height of 250 to 600 feet, and not 100 feet as originally stated, which, of course, may make all the difference. Sir Patrick's factor writes, that if the Council are satisfied the fall is still open to them. It is quite possible that an apparent fall of 100 feet may easily be convertible into one of a much greater depth. Assume 300 cubic feet falling 400 feet instead of 100 feet, and at once the net horse-power will be 150 in place of less than 40. Most falls of water are preceded by a series of small falls and rapids, and where the flow is small a pipe line from above the rapids enables the fall to be better utilised, and may also enable the power house to be located well below the falls, the after rapids often being as valuable as the main fall itself. We see no reason to doubt that an oversight may have been made, and the occasion is useful if it draws attention to the fact that there are numerous falls available for power purposes if the system of pipe lines be adopted from above to below the available total declivity. In the Southern Californian water-power plants the pipe lines and tunnels are often brought from an initial point some miles distant, so as to secure a maximum possible fall, and if this can be combined with a dam, the uniformity of flow throughout the year can be thereby very much improved.

SEPARATION OF THE IRON LOSSES OF A TRANSFORMER.*

By Prof. H. S. Carhart.

THE following elaboration of a method of separating the iron losses taking place in a transformer is based on the measurement of these combined losses at two frequencies. A series of measurements is made at each frequency for a number of different voltages. From these two series we may obtain several pairs of equations connecting together the hysteresis and eddy current losses, each pair being taken for the same value of the maximum instantaneous induction, β, of the magnetic wave at the two frequencies. From each pair of equations may be obtained both the eddy current loss and the loss by hysteresis for the voltage corresponding.

To keep the magnetic induction constant, the E.M.F. E must be proportional to the frequency. This is evident from the general formula for the effective E.M.F., which is

$$E \times 10^8 = \sqrt{2}\, \pi\, n\, A\, \beta\, N \text{ volts},$$

where n is the frequency, A the cross section of the iron, β the maximum induction, and N the number of turns of wire. If β is constant, E is proportional to n.

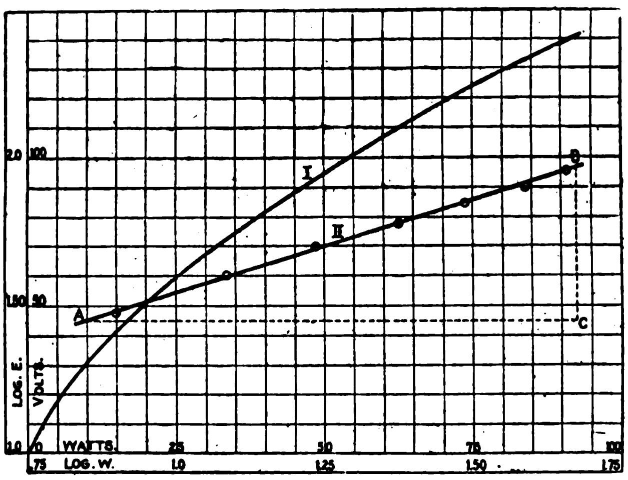
If, then, W and W′ are the total iron losses for the two frequencies n and n', both with the same value of β, we may write for the equations of these losses the following:

$$W = a\, n^2 + b\, n \qquad (1)$$

$$W' = a\, n'^2 + b\, n' \qquad (2)$$

These equations are written on the assumption that the eddy current loss is proportional to the square of the frequency. The loss by hysteresis is, of course, proportional to the first power of the frequency. The constants a and b are respectively the eddy current and hysteresis loss per cycle for the same value of the maximum induction β.

If W′ is the iron loss for an E.M.F. E′, then the value of E for the same magnetic induction in the other series is E′



n/n'. The corresponding watts W lost in the iron at the frequency n may be read from the curve representing the relation between volts and watts lost at that frequency.

The measurements below were made on a 2-kw. Slattery transformer. The current was furnished by the small laboratory alternator, which I have described in another place. (*American Electrician*, November, 1887.) The following series of observations were taken:

Series A. Frequency, 154·7.		Series B. Frequency, 108·7	
Volts.	Watts.	Volts.	Watts.
30	9·0	30	9·8
49	12·8	40	15·1
50	19·4	50	21·3
60	25·2	60	28·4
70	31·6	70	36·1
80	38·9	80	44·5
90	46·5	90	53·1
100	54·2	100	62·2
110	62·7		
120	71·5		
130	81·1		
140	91·5		

* New York *Electrical World*.

Curve I. in the diagram expresses the relation between volts and watts for Series A. It is used to find by interpolation the watts corresponding to the voltages under A in the following table. These voltages are found, as already explained, by multiplying those of Series B by the ratio n/n'. In the present case this ratio is 1·491.

Series B.		Series A.	
Volts.	Watts.	Volts.	Watts.
30	9·8	44·73	16·0
40	15·1	59·64	24·7
50	21·3	74·55	34·75
60	28·4	89·46	45·75
70	36·1	104·37	57·7
80	44·5	119·28	70·6
90	53·1	134·19	84·75

By substitution in equations (1) and (2) we may now obtain seven pairs, viz. :—

$$16 = 154{\cdot}7^2\, a_1 + 154{\cdot}7\, b_1$$
$$9{\cdot}8 = 103{\cdot}7^2\, a_1 + 103{\cdot}7\, b_1 \qquad (1)$$
$$\cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot$$
$$84{\cdot}75 = 154{\cdot}7^2\, a_7 + 154{\cdot}7\, b_7$$
$$53{\cdot}1 = 103{\cdot}7^2\, a_7 + 103{\cdot}7\, b_7 \qquad (7)$$

The intermediate equations can be filled in from the table above. Solving these equations for the eddy current losses, we get the following for the frequency 103·7 :—

Eddy loss.	Total loss.	Hysteresis loss.	Volts.
1·9	9·8	7·9	30
2·9	15·1	12·2	40
4·09	21·3	17·21	50
4·66	28·4	23·74	60
5·29	36·1	30·81	70
5·81	44·5	38·69	80
7·63	53·1	45·47	90

We have thus separated the losses for the frequency 103·7; the same equations may be used to separate them for the frequency 154·7.

Since these seven pairs of equations involve different values of the magnetic induction β, they may evidently be employed to determine the exponent of β in Steinmetz's formula for the hysteretic loss. For the same value of n the hysteretic loss in watts may be written $W = c\ ^x$, where c is a constant. Hence:

$$\log W = x \log \beta + \text{constant}.$$

But for the same frequency, β is proportional to the volts E. Let β equal k E. Then, since k is a constant,

$$\log W = x \log k + x \log E + \text{constant}$$
$$= x \log E + \text{constant}.$$

The relation between the logarithms of W and E is evidently the equation of a straight line, and the desired exponent x is the tangent of the angle which this line makes with the axis of log E. The logarithms of the loss by hysteresis and of the corresponding volts of the last table are plotted in Curve II. of the diagram. The tangent of the angle A B C, measured in terms of the two scales on which the logarithms are plotted, is quite closely 1·6.

The method obviously gives better results when the measurements are made on a transformer having iron losses which can be read on the best part of the scale of the wattmeter. The small readings are not so reliable as the larger ones.

I have applied the same method to the small transformer described in the *Electrical World*, September 18th, 1897. The plot of the logarithms gave the same result, viz., 1·6. This confirms Steinmetz's formula for the loss by hysteresis.

TOPICS OF INTEREST TO CENTRAL STATION MEN.

An address upon this subject was delivered on January 19th last by Lieut. Francis A. Badt, before the North-Western Electrical Association, Milwaukee, Wis.; and, as will be seen in the present review, there *is* much not only to interest but also to amuse central station men. He starts off on the rather threadbare—or, as he calls it, "the old, old subject of alternating *v.* direct currents," and appears to distribute his favours about equally between them—a thing, by the way, that very few electrical men are unbiassed enough to do. He then plunges into the troubled waters of "pressure," and after detailing the difficulties he experienced in getting manufacturers to produce a 220-volt incandescent lamp, practically takes the credit for its production as a commercial article. He takes considerable trouble to explain the advantages of a 220-volt direct current two-wire system over the three-wire system, and states that the former is really simpler! We should have thought it unnecessary to explain (!) this to an electrical association. The 220-volt enclosed arc lamp he considers to be a decided advance, as it can be run direct across the mains instead of using two or three in series, and as the arc is three-quarters of an inch long it practically casts no shadow. Obviously, the longer the arc, the less likelihood of shadow *from the carbons;* but he overlooks the fact that the shadows from the supports and spark catchers are much greater than those cast by the lower carbon, no matter what length the arc may be, while the colour of the light produced by any long arc lamp is usually far less pure than that from a short arc for the same expenditure of energy, and in England, at any rate, the colour and steadiness of the light are matters of considerable importance. He is doubtless right in stating that fluctuations of pressure affect a high voltage arc lamp much less than it does a low voltage lamp, and where arc lamps are required to be used on power circuits, there would probably be some advantage in using the higher pressure. Seeing, however, that on lighting circuits a steady pressure is essential on account of the incandescent lighting, its superiority even in this respect is not obvious, and we fancy that the consumer would prefer a lower pressure lamp with a reasonably steady arc and white light. He contends that "you can supply a customer with one lamp without making that lamp depend upon somebody else's lamp, doing away with all series connections." This throws rather a strong side light upon American central station practice, and reminds one of the complaint made many years ago in England by a consumer in a south coast town, that when he wanted to light a single lamp in his bath-room, he also had to light up his drawing room! the lamps being on the same circuit in a parallel series system. He states that "Our friends over the water have declared time and again, and have proven it to us mathematically, that the enclosed arc is no good; that the open arc is of greater efficiency and has many advantages over the enclosed arc, but in spite of these theoretical demonstrations the enclosed arc is the arc to-day in the United States, and the open arc for constant potential circuits is getting out of vogue entirely. It is a back number, and gives us one of the illustrations where theory and practice do not coincide. *The American is, if anything, practical,* &c." Lieut. Francis A. Badt is probably not aware of the large number of enclosed arc lamps in use in England, nor must he assume that the opinions of one or two or half-a-dozen does of necessity represent the opinions of the electrical men of England.

He thinks it will not be very long before they will have an enclosed arc lamp of 500 volts which can be attached directly across the wires of a railway circuit! But why stop short at 500 volts? Why not run up to 2,000, or 10,000 volts for that matter, and connect directly across the feeders of a high tension system? An arc lamp with a 3 feet arc would be a novelty, and *would cast no shadow!* A street lighted with a double row of such lamps would be a sight worth seeing, and we confidently expect practical America to show us the way.

Lieut. Francis A. Badt is in trouble about the "gas cap" of the enclosed arc lamp, *i.e.*, the cover of the inner cylinder, and through which the upper carbon passes. He complains that carbons vary so much in diameter, that either the carbons stick in the hole, or are so loose, that the air gets in too readily, and the life of the carbon is materially reduced. We, in England, would usually surmount this difficulty by specifying for a certain diameter of carbon, and a certain size of hole, and seeing that we got it, or else promptly return the goods to the makers. We presume this remedy has not occurred to practical Americans, and the remedy suggested by the speaker was the standardising by the Association he was addressing of the diameter of the hole and the carbon. The old story of leading a horse to the water. The Association may standardise, but the maker will supply carbons and gas caps out of standard if the purchaser is not smart enough to see that he gets what he wants. He says that all the above refers to the direct current system, *of course.* Why of course? A pressure of 220 volts is not confined to direct current systems—at any rate in England—neither are enclosed arc lamps, or two-wire or three-wire systems, and if a 500-volt arc lamp is a desiratum for direct current supply, it would be equally advantageous to alternating current systems.

His opinion is—referring now to alternating currents—that the single-phase system will eventually be the system, and makes the astonishing statement that "We have *now* (italics are ours), of course, incandescent lamps burning on alternating currents." (Must we assume that America has not been accustomed in the past to run glow lamps on alternating current circuits?) With alternating arc lamps and single-phase motors he thinks the single-phase alternating system *the* system for large areas The speaker criticised an objection made previously by a Mr. Dow: "That each customer had to have a transformer for the maximum capacity of the dwelling, or whatever it might be, and he cited that as a great disadvantage of the alternating system as against the direct current system." He (the speaker) said, "Now I think that a good deal of that could be avoided in the alternating system by using larger transformers for a number of customers," and goes on to remark that of course it could not be done economically with 50-volt lamps, and it may not be possible to do it economically with 110-volt lamps; but why not use 220-volt lamps?

We should strongly recommend our old friend of years ago to run over to England, for while we are not practical Americans, we have never used any other alternating system than the single-phase for central station supply, and he may be surprised to learn that "banking" transformers is the rule, and is nearly as old as the system itself, that we have never experienced any trouble in running incandescent lamps on alternating current circuits, that stations have been made to pay on 110-volts pressure; and, finally, that 200 or 220-volt lamps are largely used, and have been since their introduction as a commercial article. In conclusion, he draws attention to another threadbare subject, viz., the low efficiency of steam plant, and finally becomes prophetic. "The steam engine of the future (he says) will have a much higher efficiency, of course. It will do away entirely with boilers. It will be a steam engine that burns the fuel, &c."

Then he proceeds to give himself away by saying, "I am not guessing here; but I am just describing an engine which is now on exhibition on the other side of the water," &c., and after explaining that Americans are now trying to buy the patents of this wonderful engine, he goes on to describe an American Utopian city in which street railways will be abolished, and motor cycles and motor buses "running in all directions" (!) on asphaltum pavements, will be the ideal form of locomotion, and the new engine is going to help them realise it! We should like to know something more of this steam engine without a boiler, and which burns its own fuel; but we are content to wait until America has purchased the patents and blown off some of its enthusiasm. We may then hope to get some reliable information, and shall probably find that this wonderful swan is but a very inferior sort of goose after all. We have seen too many of the inventions that were going to revolutionise engineering practice to feel any excitement over one or even half-a-dozen more.

THE ELECTRIC ARC AS A TELEPHONE.

A PAPER by Hermann Th. Simon, in *Wied. Ann.*, Vol. 64, p. 233, describes some exceedingly curious experiments, which show that the electric arc is capable of acting either as a telephone transmitter or as a receiver. Herr Simon first observed accidently in an arc light a peculiar crackling noise, which he traced to the influence of an intermittent current supplying an induction coil, and flowing in a conductor, which ran for some distance parallel to the leads of the electric arc.

Experiments with the rotating mirror failed to show that the electric arc was in a state of vibration; but this was explicable on the hypothesis that the alternating induced current superimposed on the steady current producing the arc, caused so little variation in the light, that the changes could not be perceived by the eye. The alternating current, however, was quite capable of producing changes of temperature in the arc, which expanded and contracted the gases sufficiently to generate sound waves perceptible to the ear. Conversely, it was found that when sound waves were allowed to fall on the arc, variations of the current were produced, which were capable of reproducing the sounds in a distant microphone.

The following arrangement was devised to show these effects. The primary of a small step-up transformer was connected up in the circuit of the electric arc; a microphone and battery were put in circuit with the secondary of the transformer. When the end of a sounding tuning-fork was placed in contact with the microphone, the same note was heard distinctly at the electric arc. Whistling, knocking, singing, and even speech were transmitted and distinctly given out with all the most delicate variations of tone by the electric arc. With loud tones of a certain pitch, the notes given out by the arc were accompanied with a hissing sound. To collect the notes from the arc a glass funnel is held opposite to the arc, and connected to the ears by two tubes.

Herr Simon has calculated the variations of density of the gases which would be produced by the changes of the current, and found that they lie within the limit fixed by Lord Rayleigh for audible sound waves, and he fairly concludes from this, that the notes heard in the arc are due to these variations of density.

When the arc is lengthened, the sounds emitted become essentially louder and more distinct. This is due to the fact that, the resistance of the arc being greater, a greater fraction of the work of the current is expended on ~~the arc~~, and a larger volume of gas is heated.

In order to show that the electric arc is capable of acting as a telephonic transmitter, the microphone in the above-described arrangement is replaced by a telephone, and the sound waves are concentrated on the arc by a funnel. Speech, singing, whistling, thus directed on the arc, are heard distinctly at the telephone. The explanation of this phenomenon is plain, when it is remembered that the resistance of the arc varies with the density of gases through which the current passes; the variations of the resistance will produce corresponding variations of the current which, by lateral induction in the transformer, are transmitted in an intensified form to the telephone.

We do not recommend this invention for commercial use; the language transmitted through the present telephone is usually heated enough; at least, there is no necessity for passing it through an electric furnace.

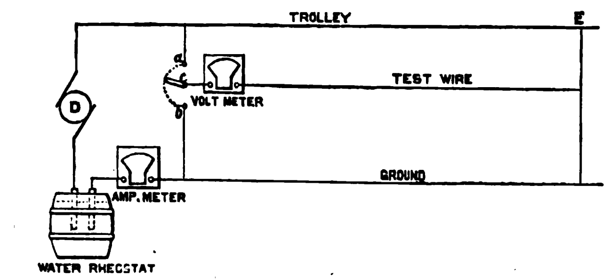
TESTING THE RESISTANCE OF THE RAILWAY CIRCUIT.

IN a communication to the *Street Railway Journal*, Mr. Sherwood F. Jeter, of Atlanta, says:—

"Having become interested in testing the resistance of the feeder and return circuits of a street railway system, it has occurred to me that a very practical rigging for making such tests, and also one that would definitely locate any trouble that might exist, would be the one outlined in the accompanying diagram. The test wire may be of iron and of any convenient size, and is strung from the station to any point at which it is desired to make tests.

"The tests can only be made at night when the line is not in use. The water rheostat is adjusted so that when the line is short-circuited, a small amount of current will flow, say, from 50 to 150 amperes. Any nice adjustment of the amount of current flowing may be made by changing the voltage of the generator so that the water rheostat need not be disturbed after once adjusting it. Now, if it is desired to test the resistance of the line from the station to a point E, a connection is made from the trolley wire at E, directly to the ground, and E is also connected with the test wire. The operator at the station now places the double-throw switch (c) on (a) and the reading of the voltmeter gives the drop on the trolley and feeders from the station to the point E, and likewise by placing (c) on (b) obtain the drop on the return circuit.

"If the resistance of the test wire is small as compared with the resistance of the voltmeter used (as would ordinarily



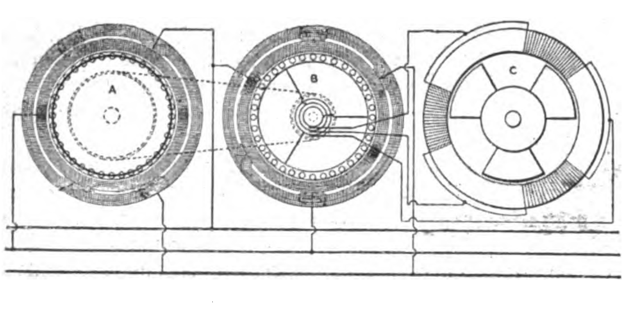
be the case), the effect of this resistance on the readings may be neglected, but if it is desirable to have them absolutely correct, the drop on the entire circuit from (a) to (b) may be taken, and the sum of the first two readings compared with this and corrected accordingly. The test-wire may also be used for signalling to the station to notify the operator when the line is ready to be tested at the various points. I have never seen an auxiliary test-wire used in making such tests, and would like to get the opinion of some of your readers as to its practicability."

ALTERNATING CURRENT REGULATION.

THE *Electrical World* for February 12th, 1898, contains abstracts of two patents recently issued for devices for phase regulation in alternating current systems.

One of these is due to Messrs. C. P. Steinmetz and Edwin W. Rice, and is called by them a phase regulator. It consists in adapting induction machines to the production of leading currents with which to nullify the troublesome, and sometimes harmful, effects of lagging currents due to any inductive apparatus connected to the supply mains.

The arrangement is diagrammatically shown in the figure, in which A represents an ordinary induction motor with short-circuited rotor windings; B is a second induction machine



driven by the motor A, either by belt, or by being direct coupled at a speed above that corresponding to synchronism with the alternating current. The rotor of the machine, B, is wound with open coils connected to slip rings, from which the induced currents can be led off and controlled in a third machine, C, which is a diagrammatical representation of another device for varying the self-induction of the three coils wound on it without altering their resistance. The internal rotative segments in C are arranged to close or open the magnetic circuits around the three windings on the fixed part. This is intended to be arranged for hand manipulation by means of a worm wheel.

The arrangement is based on the principle that inductive circuits, such as is represented by C, when inductively connected, cause lagging currents to pass in the line circuits as long as the secondary of machine, B, runs below synchronism, but cause leading currents when the speed is run above synchronism. In this way, by properly adjusting the self-induction of the coils, C, a suitable leading wattless current can be superposed to exactly balance the lagging wattless component of the line current, and thus bring the power factor to unity as far as the generators and the transmission system are concerned. The machine, A, may be any available source of power, since the essentials of the compensating arrangement are contained in machines B and C.

In practice it is preferable that machines A and B should be direct coupled. If A is a motor, its number of poles should be less than those of machine B in order to run B above synchronous speed.

DOES MOISTURE FACILITATE THE PRODUCTION OF OZONE.

By EMILE ANDREOLI.

PROF. W. A. SHENSTONE read before the Chemical Society (February 17th, 1898) a paper on "Observations on the Influence of the Silent Discharge of Electricity on Atmospheric Air," which upsets all the notions hitherto accepted regarding the production of ozone.

The learned professor says that oxygen, when diluted with nitrogen, as in the air, yields a very large proportion of ozone; 80—85 per cent. of the oxygen present may readily be ozonised in the presence of moisture, and if great care be taken, as much as 98 per cent. of the oxygen may be converted into ozone, and he adds that the presence of water promotes the formation of ozone, but retards that of nitric peroxide.

My impression has always been—and is still—that one of the conditions for obtaining a good yield of ozone is that the air must be dry, and my experience is that moist air does not give good results.

Prof. Shenstone does not explain how and why the water vapour may assist the production of ozone, while the necessity for using dry air is justified by this fact, that under the action of the silent discharge at a high tension, there is formation of water vapour and hydrogen, this latter being burnt in contact with ozone and producing heat, which destroys a considerable quantity of the ozone produced.

Years ago, a great scientist stated that water vapour absolutely prevents the production of ozone, and that no great yield of ozone can be obtained unless the oxygen is perfectly dry. This doctrine has been universally supported, and for the first time, a chemist advocates the presence of moisture for the transformation of oxygen into ozone.

Considering this question merely from a practical point of view, I will say that I have two ozonisers, the electrodes of which represent a surface of 640 square feet, and which produce a fair amount of ozone when I work them by passing dry air. I am sure that if I ventured to pass moist air between their electrodes there would hardly be any ozone generated, and in no time the apparatus would be out of order.

What is true in laboratory experiments ought to be true also when the experiment is repeated on a large scale. This does not appear to be the case, as there is an absolute discrepancy between the results obtained by Prof. Shenstone and those which are obtained by practice, and everyone interested in the production of ozone on a commercial scale, and in its application to industrial purposes, will repudiate the idea of submitting atmospheric air to the action of the silent discharge, in presence of moisture.

CORRESPONDENCE.

The Burning Question.

Mr. Liversedge lifts a corner of the curtain at Ealing. The wet sludge, says he, is drained through a certain proportion of the refuse, but he opines that this, of course, will not remove as much water as the filter press. It all depends on the drain. Suppose a nice thin layer of the rougher refuse and a free outlet. All that would remain of the sludge would be match stalks, corks and bungs, scrubbing and nail brushes, pieces of soap, candles and kitchen grease, clothes pegs, paper and rags, spinning tops and rubber balls, currants about Christmas time, Gallic literature and an occasional baby. There is a good deal of carbon in this collection which may account for the arc lamps.

A filter press, on the other hand, stops practically the whole of the solids, no matter how fine their state of division. The filtering medium becomes so close grained in a few seconds that a pressure of about 120 lbs. per square inch is required to force the liquid through. Naturally where the press is in use the amount of solids to be burnt is formidable. Why do not other towns adopt that charmingly simple drainage plan then—where a few inches of head on top of a few cinders does the whole business? Is it that they have not yet discovered the secret of dealing thus with their sludge, and at the same time giving satisfaction to the river authorities? As Mr. Liversedge hints, the thing, like the origin of Jeames, is "wrop' in a mistry."

The town of Leyton has ever listened to inventors with a greedy ear. "A Difficult Problem Solved" is a headline over the latest scheme; but the same headline has been used before to describe the exploits in sewage treatment achieved in that Eastern suburb. There was the Astropp system, two stories high, which took in wet sludge at the top, strained it (the liquid being run away in secret channels), dried the solids by hot air, and delivered them into a sack through a spout below, the whole ready and smoking hot for application as valuable manure to hungry lands. One of the great merits of this system was the small amount of solids left. A suburban garden could have taken the whole production for a year, without any symptoms of overfeeding being manifested by the plants.

This earlier solution of the problem was boomed mightily too; under cover of a marquee, solids and liquids disappeared in the most gratifying way; an earl presided, and the ears of the luncheonees were judiciously tickled by optimistic orators. As Mr. Ralph Nickleby grimly remarked, "These things have their uses in business." And, finally, the Astropp system passed into that limbo where hundreds, perhaps, thousands, of solutions of the sewage problem have preceded it.

There is a sentence in Mr. Liversedge's letter which is interesting to note. He says: "Leyton saves over £300 a year in coal in operations connected with her sewage." We should like further particulars of this saving. Is it really net? What are the operations at the sewage works requiring so much power as this sum represents? Are any coals now required? It would serve a useful purpose if Mr. L. would enlarge on this item.

It has been seriously proposed to burn the solids in London sewage, and in a way that only a genius would suggest. When you think of it, if a mere strainer will separate solids and liquids as Mr. L. says it does at Ealing, there is no sense in putting down and running costly precipitation processes with presses to deal with their resultant sludge. You have merely to pass the whole of the sewage as it comes to hand through the strainer, and the separation is effected right away. Accordingly, a man of supreme insight did suggest this way of dealing with London sewage, and published plans showing a kind of dredger with finely meshed buckets working in the sewage. This apparatus dried and burnt the solids as fast as it extracted them. It was discussed in the London press about the time eels were so plentiful in the East London water mains, and I suggested its adoption by that company for ridding their water of these, delivering stewed eels at the other end. This process never got to the marquee and oratoric stage, but expired soon after its inception for want of capital.

J. Hetherington.

Knots.

In the discussion of technical matters loose and inaccurate phraseology is always to be deprecated, and hence it is as well to decide whether a length of "a knot of cable" and "a speed of 6 knots per hour," are or are not correct. I have asserted that they are inexact and wholly unscientific, and make this statement on the authority of such men as Kelvin, Greenhill, and others. "Another Cable Engineer" takes exception to this, and begs to differ, &c. That is, he differs from the distinguished authorities named. If "Another Cable Engineer" were an authority on this matter, his opinion would be entitled to consideration; but he evidently is not, because he gives an altogether incorrect derivation of the knot.

In Harbord's "Glossary of Navigation," a knot is defined as "a division of the log line; so called from the line being divided into equal parts by pieces of string, rove through the strands and *knotted* in order."

The number of knots passing over the ship's rail in a certain number of seconds gives the *rate*, or nautical miles per hour. With that laxity of expression that so distinguishes seamen "knots per hour" were easily substituted for nautical miles, or even miles per hour. This, however, does not invalidate the fact that the original and proper meaning of the knot was that just stated.

Again, "Another Cable Engineer" derives the knot from the circumference of the earth; that is, he makes it a function of longitude. Allowing for the moment that a knot is a sea mile, his definition is still wrong. Harbord says "the length of a minute of the earth's circumference is very inadequate. . . . It was sufficient before the spheroidal figure of the earth was taken into account, and when the assumption was that the earth's circumference was a great circle, the measurement of which had not been accurately determined."

The nautical, or sea mile, or, as it is usually termed, the Admiralty mile (not *knot*), is "the length of a *minute* (not parts or knots) of a degree of latitude," but inasmuch "as the earth is an oblate spheroid, the degree of latitude increases as we advance from the equator towards the pole, and hence its 16th part, a minute, or the nautical mile, also increases (*vide* Robinson's "Marine Surveying.") The mean value of a minute of latitude, or that value on the parallel of 45° is 6,077 feet. The Admiralty have adopted as their standard mile a length of 6,080 feet which is the length of a minute of latitude on the parallel of 48°.

Again, in the latest standard text book of navigation used by the Admiralty, Stebbing's, the knot is strictly defined as a *rate* of a nautical mile per hour. "Knots per hour," then, means nautical miles per hour, per hour—either an acceleration of velocity, or a redundancy of words. It is never *meant* as an acceleration. It is, therefore, a redundant expression, that is, it is inexact and unscientific.—Q. E. D.

"Another Cable Engineer," and possibly others, may regard the whole question as a quibble, but if we admit it is a quibble, why not employ, in defining the power of an engine, so many horse-power *per minute?*

It is true that the expressions in question "have been used for scores of years by naval officers and others." It may interest "Another Cable Engineer" to know that it has been a lax practice for such to speak of minutes of arc either of latitude, longitude, or as shown by a sextant as "miles." This comparison of knots with miles and miles with minutes of arc is most curious and is characteristic of the uninstructed seaman. This misuse of terms is none the less a sure and certain sign of a deficient professional education. Lastly, no modern naval officers or writers of repute on naval service, in which, as I need hardly say, much electrical science is included, employ the objectionable expressions referred to, and I am sure that if "Another Cable Engineer" will look up the subject he will see the error of his ways.

Geo. Herbert Little,
Master Mariner, &c.

Your correspondent, "Another Cable Engineer," in last week's Electrical Review gives the circumference of the earth as 131,385,465 feet. Is not this a mistake, and should it not have been 131,385,464·287 feet? If so, the length to which he has given the name of one knot, and which he makes out to be 2·66 feet greater than the Admiralty knot should be corrected accordingly.

"Another Cable Engineer" is evidently labouring under the impression that he is replying to Mr. Little's previous letter; but instead of doing so, he gives us the above definition of a new unit of length, and then goes on to explain the use of the log-ship, apparently for the benefit of those who are unacquainted with this old-fashioned device for measuring the speed of a vessel. He sums up by saying that the whole question *appears* to be a quibble.

Now, if he does not know that *his* knot is the nautical or geographical mile, whereas Mr. Little's knot is a speed, and nothing but a speed, let him read Mr. Little's letter through once more, and then ask himself who is the quibbler.

Why not adopt Mr. Little's suggestion and use the word "naut" to express the length known as the geographical mile? One naut per hour would then be a knot, which can clearly not be a nautical mile, but must be a speed; the nautical mile being a naut, not a knot, notwithstanding your correspondent's assertions to the contrary. Surely this is simple!

X. Y.

Testing Accumulators.

If 3 kilowatts are required for a car to move up a gradient with a battery giving 50 volts, it must be evident to Mr. A. Campbell that to move it up the same gradient with a battery reduced to 45 volts will require still 3 kilowatts, and that means plainly more current in the motor armature.

The question is not how this increase is brought about, but whether experts in reporting on tests should not state which of the three conditions referred to were observed: Constant resistance, constant amperes, or constant watts in circuit during test. The first gives highest results, the second lower results, and the third lowest of all. Constant watts would, of course, be obtained in the same way as constant amperes during a test, namely, by varying the external resistance.

The Writer of the Article.

Mr. Ranken's Resignation.

Having heard that the approaching termination of my appointment has by many people been connected with the recent engine breakdown at these works, I should like to point out that my resignation was accepted by the Electric Lighting Committee nearly a week previous to the accident. The Chairman has kindly allowed me to publish his letter in confirmation of the fact.

A. W. Ranken,
Corporation Electrical Engineer, Yarmouth.

[Copy]

7, South Quay,
Great Yarmouth,
March 19th, 1898.

Dear Mr. Ranken,

It is a matter of regret to me that the resignation of your position as chief engineer should be in any way connected with the recent accident at the works. As a matter of fact your resignation was accepted on February 28th, and the accident occurred on March 5th.

Yours very truly,
Rd. Martins,
Chairman of Electric Lighting Committee.

Supply Current for Electro-plating.

I want to do electro-plating direct from the mains supplied me by the Brighton Corporation. I want a pressure of 2 volts and 15 amperes current. The mains come to me at 115 volts. How am I to lower the voltage and at the same time get the 15 amperes necessary to do my work. If you can give me an answer in your next issue I shall feel greatly obliged. Perhaps if you inserted my request in your excellent journal some eminent electrician would not think it beneath him to give a reply, which would enable myself and others to get over our difficulty.

R. T. Dick.

Gas Driven Plant.

As a subscriber to your valuable paper, I should feel much obliged if you would inform me through the columns of your journal as to the proportion of private installations, driven from gas engines *direct* to the dynamo, bears to similar installations driven *through a countershaft* fixed on the floor of the building which is lighted, *e.g.*, when the engines are put down solely for generating the electrical current, and when no other source of power is available.

Gas Engine.

Information Wanted.

Could you let me know where I can find any particulars of any methods of electrical printing with acetate of lead, other than the well-known method used in the electrical printing telegraph, of Bain, with potassium iodide and starch. Thanking you in advance.

T. J. Hughes.

LEGAL.

Crompton & Co. v. Liardet.

In the Queen's Bench Division on Thursday last week, before Mr. Justice Day, a claim for £89 3s., balance of account for supplying two electric motors, was brought by Messrs. Crompton & Co., Limited, the well-known electrical engineers, against Mr. J. E. Liardet, a gentleman living at Hyde Park Gate. Mr. McCall, Q.C., appeared for the plaintiffs and Mr. E. G. Hills for the defendant.

Mr. McCall said it was only necessary to bring before his Lordship the point in dispute. In July, 1896, the defendant sent an engineer, named Mr. Rogers, down to plaintiffs' works at Chelmsford to select two electric motors for a yacht of his. Mr. Rogers presented his report to his principal, and plaintiffs subsequently wrote a letter to defendant informing him that they supplied motors of 8 9 horse-power, with 900 to 1,000 revolutions a minute, and motors of 10½ horse-power, of 1,000 revolutions a minute. Mr. Liardet ordered a pair of motors, which were sent in due course. Defendant paid a sum of £100 on account, but the plaintiffs had been unable to obtain the balance from him.

The defendant said that for the past 26 or 27 years he had been engaged in electrical experiments, in which he had been assisted by a Mr. Rogers. In July, 1896, he was fitting up a launch of 65 to 70 tons. This would be the largest yacht afloat driven by electricity. After his assistant had seen certain motors at the plaintiffs, at Chelmsford, he ordered a pair of twin motors from them, which were to have revolutions of from 500 to 1,000 a minute. The motors were delivered about August 16th, and immediately afterwards he forwarded the plaintiffs a cheque for £100. He stated at the same time that the motors were incomplete, and asked that they might be completed. Time passed, and the season became too advanced to have a trial test. Under the circumstances, he wrote to plaintiffs, saying that they must wait for the balance of their account until he had made a trial test of the motors. He found that the motors were not equal. They were to be used for twin propellors, and, therefore, the speed should be equal, otherwise the rudder would always be over, and thus retard the speed. The motors were two right-hand ones, and were not suitable for driving twin propellers in a launch. One motor ought to be a right-hand and one a left-hand motor, in order that both might work properly.

Cross-examined: The motors were to be paid for on delivery, but when he received them he saw at once that they had been wound wrongly. He admitted that he had written subsequently to plaintiffs saying that he hoped to try the motors in April, when, if they were satisfactory, he would pay the balance. But he was suspicious of the motors from the first sight of them.

His Lordship gave judgment for the plaintiffs for the amount claimed.

Williamson & Joseph, Limited, v. London County Council.

This was a claim which came before Mr. Under-Sheriff Burchell and a jury at the London Sheriffs' Court last week, for compensation in respect of the compulsory acquirement by the L.C.C., of riverside premises at Coxon Place, Horseleydown, under the Tower Bridge Approaches Act, 1895. Mr. Dickens, Q.C., and Mr. Church, represented the claimant, while Sir W. Marriott, Q.C., and Mr. H. C. Richards, M.P., were for the L.C.C. The claim was stated to be principally regarding fixtures, and it was agreed that the figures with regard to these, should not be placed before the jury, but should be considered by Prof. Robinson for defendant, and Mr. Sherley Price as arbitrators between the parties; the learned Under-Sheriff to appoint an umpire, who should decide between the arbitrators in the event of their failing to agree. Sir Wm. Marriott mentioned that the items referred to amounted to something like £3,560, and, in answer to the learned Under-Sheriff, said the jury would only have to consider the value of the lease and loss of business. The award of the arbitrators or umpire would be added to the verdict.

Mr. Dickens, in opening the case, said the claimants were Messrs. Williamson & Joseph, Limited, who carried on business at the premises mentioned as mechanical and electrical engineers. The business was established in 1889, in which year the premises were leased for a term of 21 years from March, 1890, at a rental of £180 per annum. Notice to treat was served in July, 1896, but it was not until the latter part of 1897 that the County Council, as a result of negotiations, gave the claimants notice to vacate their premises on or before March 25th next. This date was, however, subsequently altered to June 24th. Counsel proceeded to refer to the various advantages of the premises in question, which were stated to be particularly suitable for the carrying on of the claimants' business. It had not been found possible to secure other premises at a less rental than £300 a year. For the purpose of comparison counsel gave figures, which showed that the sales had been doubled since 1895.

Mr. Edward L. Joseph, manager of the company, said that there had been a steady increase in the sales since the conversion of the business into a limited company. The County Council gave a notice to treat in July, 1896, which had a very injurious effect on their work, because they could not guarantee the date of delivery of an order. The present offices were at 92, Queen Victoria Street, about 12 minutes' walk from the manufactory. He had made about 200 inquiries, and could not find suitable premises equal to those taken in the immediate neighbourhood. He had obtained a new factory at Highbury, four or five miles away, on lease for 21 years, at a rent of £200 a year, but they would have to fit up and repair the premises, and make other alterations, at a cost of £1,500; the accommodation was one-third less than in the other premises. Under the most favourable circumstances the removal could not be carried out under four months, owing to the nature of the fixed machinery, and there being about 1,000 different and small parts that must be skilfully removed. They would have to refuse business for four months, and he estimated his total loss during that time at £2,000. The £1,500 was what they must spend on the new premises; but they did not charge the County Council with all that sum. The notice to treat came at a critical time, when the business was beginning to "turn the corner." The works undoubtedly showed a profit in 1897.

Evidence was given by Mr. Edward Stimson, auctioneer and valuer (Messrs. Stimson & Sons); Mr. Francis J. Bisley, surveyor and auctioneer (Messrs. F. J. Bisley & Sons); and Mr. Frederick F. Smee, surveyor and valuer (of Messrs. Bradshaw, Brown & Co.), as to valuation.

Mr. Henry Sherley Price, member of the Institute of Mechanical and Electrical Engineers, said he averaged two millions a year in valuations of engineering works. He put the damage on loss of trade consequent on disturbance of the business at £2,000, and considered that it would take at least three months to re-organise, remove into the new premises, and get to work on the same basis as at the present moment. During that three months the whole of the establishment charges would be running, whether any work was done or not. He had taken the gross profits according to the 1897 balance-sheet, and divided them by four, producing £870 as part of the expenses that would run on during the three months. He had written to the Council asking them not to stop the business, but they would make no offer.

Some discussion arose as to the agreement which had been come to with regard to the fixtures, Sir William Marriott stating that the County Council had offered the company the whole plant and materials. Ultimately the Under-Sheriff took a note that the arbitrators were to assess the value of all the fixed plant and loose tools belonging to same, all tenants' fixtures and improvements, and the damage to machinery in course of removal. Part of the business could not be carried on at one place while the machinery was being removed.

Mr. F. Charrington and Mr. F. H. Nalder gave corroborative evidence that the business would be practically stopped for three months.

Sir Wm. Marriott, opening the case for the County Council, said the jury had nothing to do with the removal of the fixed plant and machinery, and would only have to decide the value of the lease and the loss of business. As a matter of fact, the premises were let in 1890 at £180 per annum, whereas it was contended on behalf of the claimants that they were now worth £275, which was a very considerable difference.

Mr. Wm. Dalton, of the Surveyor's Department, Scotland Yard; Mr. Andrew Young, F.S.I., valuer to the County Council; Mr. James F. Field, F.S.I. (Messrs. Field & Sons); Mr. Wm. Eve, F.S.I.; and Mr. Henry Stock, F.S.I., gave evidence for the defendants as to the questions of value and convenience.

Prof. Robinson, professor of civil engineering at King's College, was of opinion that the claimant's business could be re-established within two months.

After counsels' speeches and the Under-Sheriff's summing up, the jury gave a verdict for £1,450, divided as follows: £350 for the value of the lease; and £1,100 as loss of trade.

The parties agreed that Mr. F. Terry Horsey, F.S.I., of 11, Billiter Square, E.C. (Messrs. Fuller, Horsey, Sons & Cassell), should be appointed by the Court as umpire in the two heads of claim set aside.

Holophane, Limited, v. The Stewart Electrical Syndicate, Limited.

In the Chancery Division on Saturday, before Mr. Justice North, Mr. Swinfen Eady, Q.C., said he had a motion to restrain the infringement of the Holophane patents and from passing off. The defendants appeared, and asked time to answer evidence, and had agreed in the meantime to keep an account.

Mr. Neill, for the defendants, said the patent was a singularly complicated one, and its validity was disputed. It seemed to him a very inconvenient course to try a case of this kind in motion, and he suggested it should stand till trial or further order, he undertaking in the meantime to keep an account.

Mr. Eady said he could not agree to that, as there was a question of passing off. He thought, after hearing the evidence, that his Lordship would grant an injunction even as regarded the patent itself.

Mr. Neill said that really it was pure and simply a patent action.

Mr. Eady: I cannot accept that.

Mr. Neill said that the validity of the patent would shortly come before Mr. Justice Kekewich in an action which was pending.

Mr. Eady said he could not accept an undertaking until the trial, but only until the motion was disposed of.

Mr. Neill said he would give an undertaking until the motion was disposed of.

GLASGOW TELEPHONE INQUIRY.

Sheriff Jameson's report, from which we extract the following, has been placed before the Glasgow Corporation. After referring to the number of witnesses called (84), the Commissioner states that he considered he was not entitled to allow an inquiry into the cost of working. He then gives a detailed description of the exchange system in Glasgow district, and proceeds to answer *seriatim* the question to which his attention had been drawn in his instructions.

(1) Is the Service, As Far As It Goes, Efficient?

He was of opinion that it was not. This was due, directly or indirectly, to the want of a metallic circuit, but a considerable proportion of the enormous number of complaints was not referable to that cause alone, and might have been remedied by more thorough supervision in the central and junction switch rooms, by more care in connection with wires in contact, more prompt attention to complaints against operators, and other precautions. In support of this he refers to the numerous complaints which the correspondence showed had not been manufactured for the occasion.

(2) Is the Service Adequate, and are there a Sufficient Number of Call Offices?

Dealing with this question, he says that no witness was adduced who complained of being deterred from joining the exchange system on any condition as to way-leave or otherwise, and he does not think it is at all unfair in a person who uses the telephone himself being requested to give facilities for the extension of its use to others. In regard to the five years' condition, he says it seems not unreasonable that the company should decline the expense of putting up a wire in connection with their exchange without some security that the expense will not be practically thrown away by a subscriber leaving his premises at the end of a short period. He holds that the number of call offices is sufficient to meet the reasonable requirements of the public.

(3) Is the Price Charged for the Service Reasonable?

After stating the rates, he says: "It appears to me that these rates are not unreasonable, except in some outlying districts, such as Bearsden, Pollokshaws, and others, in which case, I think, they ought to be reduced. But speaking generally, I may say that the rate is what is called the £10 rate for places of business within a half-mile of the Exchange, which was the Post Office telephone rate for distance between a quarter and a half mile up till October 1st last, when a reduction took place to £8. Comparing the rates charged by the Telephone Company in Glasgow with the table of rates in foreign countries, I do not consider that they are excessive. The example which all the Corporation witnesses took as a comparative example was Stockholm. They assume that Stockholm is comparable with Glasgow, and that the rates there should rule the rates in Glasgow. For my own part, I can hardly imagine two more dissimilar places in almost every conceivable respect. It is, moreover, noticeable that a great number of the witnesses who were called for the discontented subscribers said they would not object to the £10 rate if the service was efficient, and if it be the case, as proved by Mr. Gaine, that each message in Glasgow costs 0·57 of a penny, or practically a halfpenny a message, I do not think it can be said that the price is not reasonable."

(4) Is the Inefficiency Due to the Refusal of Facilities by Glasgow Corporation, and is such Refusal Reasonable?

"I am of opinion that the main cause of inefficiency of the present telephone exchange service in Glasgow is, that it is worked by an overhead single-wire system, with an earth return, in a city where there is an enormous amount of concentration of wires to one point greater than even to one point in London, and where, owing to the system of electric lighting in one of the underground railways, an overhead system is peculiarly liable to be rendered inefficient. These objections will be got over by the company making an overhead twin-wire system, but I think it would be most unreasonable to require them to do so. The National Telephone Company resolved, in February of last year, to introduce the metallic underground system in Glasgow, and on February 26th, 1896, applied to the Corporation for assistance, which was refused. My opinion, accordingly, is, that the continued inefficiency of the present telephone exchange service in Glasgow is, in a great measure, due to the refusal of facilities to the Telephone Company by the Corporation of Glasgow for constructing an underground metallic circuit system. The Sheriff examines the evidence given by the representatives of the Corporation on that point, and gives his conclusions as follows:—It humbly appears to me that this evidence is self-condemned (1) so far as the inconvenience of the public is concerned, the inconvenience of the Corporation laying an underground system for themselves, and the National Telephone Company laying an underground system under the supervision and control of the Corporation, would be in identically the same position. Beyond this, the objections seem to me to be purely of a sentimental and fanciful kind. The objection to giving leave to the Telephone Company because it is a dividend earning company, appears to me quite absurd, when it is considered that the operation proposed is really for the benefit of the public, and will, in that view, cause the company a large expenditure of money; and, further, that the company are willing to pay the Corporation a sum in respect of the leave to be given under their streets. I may remark that the way in which some members of the Corporation speak of the streets as the patrimony of the city of Glasgow is absurd, whether regarded from the point of view of law or of fact. My inference on the whole evidence is, that the true cause of the refusal of the Corporation of Glasgow to allow the Telephone Company wayleave under their streets is that they are resolved if possible to establish a telephone system of their own by means of which they would be able to extinguish the National Telephone Company altogether, so far as Glasgow is concerned, and supply a better and cheaper service to the inhabitants of the present Glasgow district telephone area. My answer to this question accordingly is, that the continued inefficiency of the telephone service in Glasgow is, for the most part, due to the refusal of the Corporation of Glasgow to allow the National Telephone Company to construct a metallic underground system underneath the streets of the city; and I am further of opinion that such refusal is not reasonable or justifiable on grounds of policy or otherwise, unless it be thought that the Corporation are justified in their refusal because they desire to establish a telephone system of their own, and to place the National Telephone Company at an enormous disadvantage in competing with them for the patronage of the public."

(5) Is it Expedient to Grant the Glasgow Corporation a License?

The Sheriff answers this question at length, and concludes as follows:—

"In these circumstances, and apart from the difficulty of the situation, which I shall hereafter advert to, I should have been prepared to state as my opinion that it is not expedient that the Corporation of Glasgow should obtain a license to carry on the business of telephony within the present Glasgow district area, and that for these reasons:—

"1. A telephone service in this country does not exist for the benefit of all classes of citizens, but for that of a limited number. It is therefore not an object to which the "Common Good" of a burgh ought to be applied.

"2. Whether the foregoing proposition be correct or not, it is my opinion that the Corporation of Glasgow are not at present entitled to apply the burgh funds or funds raised on the security of the burgh "Common Good" to the establishment and maintenance of a telephone system outside of the burgh boundaries. To enable them to do so, a special Act of Parliament would be necessary, and it seems inappropriate for the Postmaster-General to grant the license to do something which at present it is otherwise illegal for the Corporation to do. Perhaps this might be got over by the license being given under the condition that it should not be available beyond the boundaries of the City of Glasgow till Parliament has sanctioned the proposed action of the Corporation.

"3. On general grounds of public convenience it is inexpedient to have two telephone systems or two telephonic authorities within the same area, as this leads to the necessity of members of the public subscribing to both systems, or suffering from delay in the transhipment of messages from one system to the other.

"4. Because the establishment of a second telephone system may render the acquisition of the telephones in Glasgow by the Government at the end of 1911 more difficult and expensive.

"5. Because up till this time the Corporation have not produced satisfactory evidence that they could successfully finance and work the proposed system without the risk of putting a new and serious burden on the ratepayers of Glasgow.

"In my opinion the reasonable solution of the matter would be that the Corporation should grant to the National Telephone Company the same facilities for laying a metallic circuit system underground as the large English municipalities have already done, and under similar safeguards.

"But the Corporation of Glasgow at present state that they will never consent to the National Telephone Company being allowed to lay an underground system in Glasgow, and it is clear that unless this is done, the telephone service in Glasgow will continue to be inefficient, which is a state of matters that ought not to be allowed to continue.

"The question therefore arises whether, excepting the present situation, it would not be expedient, notwithstanding all the objections I have above pointed out, that the license they now ask should be granted to the Corporation, throwing on them the whole responsibility of their proposed undertaking.

"One way out of the difficulty would be for the Post Office to establish a telephone exchange in Glasgow themselves, with an underground metallic circuit system of wires. To do so would seem to be authorised by clause 18 of the agreement between the Postmaster-General and the National Telephone Company, dated March 25th, 1896.

"If this course does not recommend itself to Her Majesty's Government, then, in the interests of the public who use the telephone in Glasgow and district, I am of opinion that it would be expedient to grant to the Glasgow Corporation the license they have now requested, provided that they are able to satisfy the Postmaster-General that financially their scheme is sound, and that they have the means of carrying it out."

The following correspondence has passed between the Secretary of the Post Office and Sir James Marwick:—

"General Post Office,
"*March 16th*, 1898.

"The Town Clerk, Glasgow.

"Sir,—I am directed by the Postmaster-General to forward to you, for the information of the Corporation of Glasgow, the accompanying copy of the report which was made to the Lords Commissioners of Her Majesty's Treasury by Mr. Sheriff Jameson after his recent inquiry into the telephone exchange service.

"The Duke of Norfolk understands that the Corporation have arrived at the conclusion that they could not confine to their own municipal area the operations of the telephone exchange system which they desire to establish; and he agrees with the Corporation in thinking that there would be grave public inconvenience in instituting an exchange system confined to the area of the municipality alone, and which would exclude from its operation many neighbouring districts in which citizens of Glasgow reside or carry on their business. It is evident, however, to his Grace that, outside the limits of their own jurisdiction, the Corporation might encounter the same difficulties of obtaining wayleaves for the necessary underground wires which have hitherto embarrassed the efforts of the National Telephone Company to make their own system efficient in Glasgow itself.

"Whether this is so or not, however, the Postmaster-General is advised that the Corporation in the present state of the law has no power to carry on the business of a telephone exchange, either within or outside the limits of the municipality, and in these circumstances he is precluded from assenting to the wishes of the Corporation by issuing a license.—I am, Sir, your obedient servant,

S. Walpole."

"City Chambers, Glasgow,
"S. Walpole, Esq., Secretary, "*March 19th*, 1898.
"General Post Office, London.

"Sir,—I beg to acknowledge receipt of your letter of 16th instant, enclosing copy of the report which has been made to the Lords Commissioners of Her Majesty's Treasury by Mr. Sheriff Jameson, and intimating the views of His Grace the Duke of Norfolk upon the applications by the Corporation for a telephone license.

"I have submitted your letter and Sheriff Jameson's report to the committee of the Corporation.

"The committee have not had time to consider the report in detail, but they observe that Sheriff Jameson states, in concluding it, that if the Government do not see their way to establish a telephone exchange in Glasgow, with an underground metallic system of wires, he is of opinion 'that it would be expedient to grant to the Glasgow Corporation the license they have now requested, provided that they are able to satisfy the Postmaster-General that, financially, their scheme is sound, and that they have the means of carrying it out.' The Corporation will be glad to have an opportunity of satisfying His Grace upon both these points.

"In reply to your letter, I am instructed to beg his Grace to give consideration to the following statement:—

"1. The Corporation have not arrived at the conclusion that the operations of the Telephone Exchange system which they desire to establish, can not be confined to their own municipal area. The fact is simply this—after ascertaining that the authorities of the various burghs adjoining the city were anxious that the Corporation's exchange, if instituted, should include their burghs, the Corporation, on September 24th last, made an application for the wider area, and they believe it is in the public interest that their exchange should include that area. But they are convinced that, should his Grace unfortunately be unable to grant the license for the larger area, a great public advantage would be secured if the Corporation obtained a license for the municipal area. In that view they desire to remind his Grace that their application of August 12th, 1893, for a license for that area, has never been withdrawn, and is still before him.

"2. The fact that the Corporation made an application in 1893 for a telephone license for the municipal area, and have since frequently, till last autumn, pressed upon successive Postmasters-General the desirability of granting it, is, the Committee trust, sufficient evidence that the Corporation can not concur with His Grace in thinking that there would be grave public inconvenience in instituting an exchange system confined to the area of the municipality. They believe, on the contrary, that a larger number of persons would benefit by a license covering the extended area, and that the public interest would be promoted by the granting of a license for that area. At the same time they believe that the trade and commerce of the city would be greatly benefited by the institution of a municipal service, though its operations were confined within the city boundaries, which extend to 12,000 acres, and embrace a population of upwards of 700,000. Even were the suburban districts excluded from the advantages of the proposed new system, the telephonic facilities which these districts at present possess would not thereby be taken away or diminished. The committee believe that, if the applications which they have made were granted, one result would be to place telephonic facilities for business purposes within the reach, for the first time, of a body of citizens exceeding in number those who at present use the telephone. But the conferring of that advantage could in no degree subject the present subscribers to inconvenience.

"3. The fact that the municipal authorities of the burghs surrounding Glasgow have come forward to ask that the application of the Corporation, extended so as to include those burghs, should be granted, indicates very clearly that no difficulty in connection with wayleaves in those burghs need be apprehended. The Corporation at present supply those burghs with gas, water, and tramway facilities, and their water and gas pipes and tramway lines are laid in and on their streets, yet no friction has ever arisen regarding these matters. The committee do not entertain the slightest doubt that they could, as in the case of their other extensive undertakings, carry on a telephone exchange as efficiently in the suburban burghs as within the city.

"4. The Corporation cannot admit for one moment that the efforts of the National Telephone Company to make their system in Glasgow efficient have been embarrassed by difficulties in obtaining wayleaves for underground wires. It was not till long after the Corporation, induced by the complaints of the citizens, had applied to the Postmaster-General for a license, that the company even asked such wayleaves. It is to be observed, moreover, that the company has never sought to take advantage of the railways and underground tunnels within the city.

"5. The Corporation are aware that they have no statutory power to carry on the business of a telephone exchange, but, in the event of the Postmaster-General granting them a license, they would be in a position to press upon the Government the desirability of bringing in a public Bill to give corporations the requisite powers; or, if the Government were unable or unwilling to do so, they would themselves promote a private Bill in the next session of Parliament to obtain those powers. The Postmaster-General will not fail to see that, unless the Corporation were able to satisfy Parliament and its officers that a license was actually available, it would be inexpedient in the highest degree for them to incur trouble and expense in asking Parliamentary powers to do what, without the license sought, they could not possibly do.

"As his Grace has been so good as to indicate the grounds on which he has arrived at the opinion intimated in your letter, and as these grounds involve an entire misapprehension of the position which the Corporation has consistently held since 1893, and also of the conditions on which the Corporation could apply for the necessary Parliamentary powers to establish local telephones, I have been instructed to beg that his Grace may be pleased to reconsider their application in the light of what is now stated.

"I have the honour to be, Sir, your obedient servant,

"J. D. Marwick, *Town Clerk*."

Announcement.—The proprietors of *Trade and Industry* inform us that they have secured the services of Mr. John Strahan Smith as the editor of *Trade and Industry*. They also announce that *Aluminium and Electrolysis* and the *Journal of Acetylene Gas-lighting and Carbide of Calcium Review* will be published in future, on behalf of the proprietors at the offices of *Trade and Industry*, 161, Strand, W.C.

Best & Lloyd.—It is announced that for personal and private reasons the firm of Best & Lloyd has been registered as a limited company, taking possession of the Birmingham works and the business on March 31st, 1897. All debts owing by, and all accounts due, will be paid and received by Best & Lloyd, Limited. The *personnel* of the management will be as hitherto.

Birmingham Electrical Exhibition.—On Monday last an Electrical and General Trades Exhibition was officially opened at Bingley Hall.

Books Received.—"Commercial and Domestic Telephony," (A popular guide). By M. Byng, M.I.E.E., and F. G. Bell. Published by General Electric Company and Whittaker & Co.

"Treatise on Chemistry," Vol. II. The Metals. By Profs. Roscoe and Schorlemmer. Published by Macmillan & Co., Limited. 31s. 6d.

Catalogues.—The London Smelting and Refining Syndicate, of 39, Victoria Street, S.W., has issued a pamphlet, illustrating and describing the various descriptions of machinery, materials and chemicals for the electro-deposition of metals supplied by it. This syndicate also undertakes the complete equipment of plating, electrotyping and refining plants. In looking through the list, we observe lead-lined vats, and vats for differential or localised electro-plating, rocking or sliding frames for vats, scouring trough, burnishers, vats for quickening solution, filtering frames, brushes, and a variety of accessorial and other apparatus and fittings. There is a number of interesting illustrations showing some of the operations, and at the end of the pamphlet are general remarks regarding iridium, and on the electro-deposition of cadmium.

Messrs. Geo. Richards & Co., Limited, of Broadheath, Manchester, have issued new illustrated catalogues of their machine tools and appliances, and wood-working machinery. Both lists are dated January, 1898. The machine-tool list describes the firm's planing machines, standard lathes, giving sketches of the various parts, drilling, tapping, slotting, boring, milling, grinding and other machines. The wood-working machinery catalogue deals with band and circular sawing machines, planing wood-turning lathes, boring stand, saw sharpening, moulding, mortising, and various other machines for wood-working.

From Messrs. Francis & Spilsbury, of 20, Bucklersbury, E.C., we have received a copy of Mr. A. P. Lundberg's catalogue which we reviewed last week. On this list Messrs. Francis & Spilsbury's name is printed as London and south country agents. The firm is also agent for Heaton & Smith's patent switches, a list of which is included.

Change of Address.—Mr. Robert Hammond has removed from Ormond House, Great Trinity Lane, E.C., to 64, Victoria Street, Westminster, S.W.

Church Lighting.—The National Electric Free Wiring Company, Limited, have just completed the installation of the electric lighting in the Palace Gardens Church, Notting Hill.

The order for installing the electric light in St. Barnabas Church, Kensington, has been placed in the hands of the same company. The company's patent system of wiring is being used in both cases.

Cowper-Coles's Parabolic Reflectors.—We are informed that the offices of the Reflector Syndicate, Limited, have been removed from 2, Carteret Street, to 39, Victoria Street, Westminster, S.W.

Dissolutions of Partnerships.—Messrs. H. Nunns and E. Sykes (Messrs. Nunns & Sykes, electrical engineers, South Parade, Halifax) have dissolved partnership by mutual consent.

Messrs. P. S. Brook and J. A. Hirst (Brook, Hirst & Co.), electrical engineers, Northgate Electrical Works, Victoria Road, Chester, have dissolved partnership by mutual consent. Mr. P. S. Brook attends to debts.

For Sale.—The Southampton Corporation invite offers for the purchase of a loco. boiler and a slow speed (Robey) horizontal engine now at the electricity works. See our "Official Notices" this week for particulars.

Laying New Mains.—The London County Council is at last taking steps in order to minimise the traffic disturbances, due to the constant breaking up of the streets. In two cases on Tuesday the Council, in sanctioning the laying of new mains by, among others, the Charing Cross and Strand, and the Metropolitan Electric Supply Companies, stipulated that in the main thoroughfares concerned, the work, when once commenced, should be carried on continuously, both by day and night, until completed.

L.C.C. Highways Committee.—The following were elected members of this committee, who are concerned with tramways, telephones and electric lighting, at Tuesday's meeting of the London County Council:—J. A. Baker, J. W. Benn, T. L. Corbett, W. H. Dickinson, J. S. Fletcher, E. A. Goulding, W. Haydon, N. W. Hubbard, Sir John Hutton, W. O. Johnson, R. Parker, R. C. Phillimore, Lieut.-Col. C. Probyn, P. J. Rutland, J. Thornton. It will be noted, with much regret, that the name of Earl Russell is excluded from the list. The noble earl made an eloquent statement on his own behalf, but this was of no avail, and the loss of his services on the committee will be a loss to London as a whole.

Liquidation Notices.—A general meeting of the Electrical Advertising Syndicate will be held at 164, Gresham House, E.C., on Tuesday, April 19th, at 3 o'clock, to hear an account of the winding-up operations from Mr. J. W. Jefferies (liquidator).

The British Electric Installation Contractors, Limited, will hold a meeting on May 2nd at 50, Foregate Street, Worcester, to hear an account of the winding-up operations from the liquidator, Mr. W. J. Hill.

Lists.—From the International Trading Company, of 35, Queen Victoria Street, E.C., who are the sole agents for the Chemnitz Electrical Company, Limited, we have received illustrated price lists, Nos. 1, 2, and 4. These deal with continuous current dynamos and motors; rails, regulators, and resistances; and arc lamps, lanterns, &c. A variety of types of motors and dynamos are shown by means of good illustrations, tabulated figures and prices being given. In List 2, regulating resistances, magnetic switches, motor starting apparatus, automatic current regulator, reversing and starting apparatus, sliding rails, and belt tighteners are detailed. List 4 contains description of the "Chemnitz" arc lamps, for continuous and alternating currents, stage projectors, lanterns, ornamental and otherwise, for arc lamps and lamp accessories.

Ozonisers.—The Electric Ozone Syndicate, Limited, of 5, New Union Street, Moorgate Street Station, is now manufacturing Mr. Andreoli's commercial ozone generators, which are entirely made of aluminium. The advantages claimed for these improved apparatus are the following:—The yield of ozone is large (about 100 grammes per horse-power-hour). There is no rise of temperature in these ozonisers which may damage them, or cause a loss of ozone. These ozone generators can be worked in a continuous manner, and can be made of any size to produce from 100 grammes to 1,000 grammes and more per hour. The syndicate already has several large ozonisers on order.

Personal.—Mr. E. J. Clarke announces that he has severed his connection with the Electrical Power Storage Company as assistant works' manager and works' foreman, after 13 years service, to undertake the management of the "Hart" Secondary Battery Company, Limited, at Crispin's Wharf, Stratford, E. We extend our best wishes to Mr. Clarke for success in his new venture.

Russia.—A company has just been formed with a capital of £50,000, to be known as the Allgemeine Electricitäts Gesellschaft, St. Petersburg. The Allgemeine Company of Berlin is interested in the new concern.

Synagogue Fittings.—The *Jewish Chronicle* contains an article regarding the formal inauguration of the electric light in place of gas at the St. John's Wood Synagogue. The fittings, consisting of 20 3-light electroliers, 10 3-light brackets, four 10-light electroliers, four 3-light candelabras, and two 5-light candelabras, were supplied by the Edison & Swan United Electric Light Company, Limited, and are of unique design, harmonising well with the general character of the interior of the building. They are in the Moorish style, generally resembling Moresque candelabras and lamps. The "Mogan David" has been utilised as an ornament in the design which is pierced in stout brass metal, being solely hand made. The great centre candelabra and 3-light pendants, suspended between the arches of the ladies' galleries, which to heighten the design have been studded with coloured cut-glass gems, give a very pretty effect. The whole of the fittings are of a special and very handsome design.

Telephones in Hospitals.—In our issue of November 12th last, we noted that the Private Wire and Telephone Installation Company's tender for fitting telephones in Guy's Hospital had been accepted. The same company has now been ordered to extend its system all over the premises.

ELECTRIC LIGHTING NOTES.

Aberdeen.—Prof. Kennedy has submitted his notes on the report of Messrs. Smith & Blackman on the proposed electric lighting extensions to the west end and other points. He considers the proposal a wise one. He agrees with the engineers that it is advisable as far as possible to supply current for all purposes in Aberdeen from one station, and concurs with them that it would be better to adopt a high tension continuous current system of feeders, with rotary transformers, than to use low tension feeders working at so small a current density as 500 amperes per square inch. If the increased plant at the electric station will give a pressure of 550 volts, the delivery of the 400 kilowatts to consumers at the west end would require two pairs of cables, each having an area of 0·67 square inches, and all that the Corporation would have to provide would be these cables without any other apparatus either inside or outside the station. In working the station they would simply have to arrange that one of the higher voltage machines should always be working on the west end feeder. The cost of this arrangement would be £5,750. Whether it would be best for Aberdeen to adopt the simple feeder system with the drop of 110 volts, or to adopt the booster system, must depend upon the time at which they expect to be able to deliver current to the west end and the rate at which they expect the demand to come on. As to these points the resident engineers must speak. But the professor advises the Council most distinctly that he should prefer either of these arrangements to the system with 2,000 volts, as he believes it would be not only considerably less in capital cost, but also more efficient in transmission. Electric traction and dust destructor schemes are also considered by the professor.

Arbroath.—The public library buildings are lighted electrically. The plant put down by Messrs. W. Dixon & Co., of Glasgow, comprises a 14 H.P. Crossley gas engine, E.P.S. accumulators, &c. Arc lamps are in the picture galleries, and incandescents in other parts.

Bath.—The Electric Lighting Committee presented a 43-page report at the last Council meeting.

Birkenhead.—The street lamps along the Approach to Woodside Ferry are now lighted by electricity.

Cardiff.—The borough electrical engineer has reported that during February the income was £664 6s. 7d., which was an increase on the amount reported in February of last year. The number of lamps now is nearly 16,000, and 1,420 are about to be added.

Chester.—Mains for the supply of public and private lighting are to be laid in a number of streets at a cost of £950.

Croydon.—The Croydon County Council has requested Prof. Kennedy to report upon the proposed acquisition of the works under the Crystal Palace Electric Lighting Orders, having in view the provision of a supply of current to the South Norwood district as well as Upper Norwood. Prof. Kennedy is also to report upon the cost and best mode of an extension up the London Road as far as Thornton Heath pond.

Dingwall.—The Town Council has agreed not to insist on the production of the specification of the electricity works until the proposed public electric company is formed.

Garston.—The Urban Council on the 17th inst. resolved on the recommendation of the General Purposes Committee to erect a refuse destructor and electricity station on St. Austin's Mount, Garston Old Road, at a total cost of £25,000. Mr. F. H. Medhurst was appointed electrical engineer.

Gourock.—A report on electric lighting has been presented to the Burgh Commission. The estimated cost of an installation would be about £8,600, including plant sufficient to light the whole of the burgh and for the erection of 16 arc lamps for street lighting.

Hackney.—The Vestry had a discussion in committee last week with reference to the proposal of the Electric Extension Company, Limited. The matter was again adjourned.

Hampstead.—The Vestry will apply to the London County Council for sanction to borrow £51,500 to meet the expenditure on the electric lighting capital account up to the 25th inst., instead of £50,000 as previously agreed upon. Another loan of £18,000 to meet the expenditure on the new plant to be laid down before next winter is to be applied for. The Lighting Committee recommended that Wright's patent demand indicators be fixed on all consumers' premises present and future. The recommendation was referred back to the committee for further consideration and explanation. The same committee also reported that, with reference to the letter from Messrs. Ferranti, Limited, on the subject of their contract for the supply of new plant at the central station, they had instructed the Vestry Clerk to inform Messrs. Ferranti that the plant is not at the present time running satisfactorily; that the Vestry is not prepared to fall in with their suggestion that the periodicity of the present machines should be increased; and, further, that the late engineers' strike had nothing whatever to do with the completion of the first contract. Approved.

High Wycombe.—Messrs. Hodges & Todd have been appointed by the Town Council to inspect and report upon the works of the High Wycombe Electricity Supply Company until same are completed.

Horsham.—At the last District Council meeting, a special committee which had made investigations and visited Tunbridge Wells recommended that an application be made for a provisional order, and that Mr. Hawtayne be engaged to prepare a scheme. The report was adopted.

Huddersfield.—The Corporation has appointed a subcommittee to confer with the Elland Council with respect to its application for a supply of electricity for Elland from the Huddersfield works. This month's returns show that there are 43,295 lamps connected at Huddersfield, an increase of 729 over the previous month.

Islington.—Residents in Highbury New Park are asking for the electric light.

The Vestry is to lay mains along a considerable portion of St. James's Road for the purpose of lighting Liverpool Road; to continue the mains and erect lamps throughout this thoroughfare; to lay conduits and mains on one side of the road, and to erect 13 arc lamps (cost £1,260), also to extend the arc lighting through Parkhurst Road, thus completing the line of lighting direct to Holloway Road. Conduits and mains will be laid both for public and private supply on both sides of the road, and 13 arc lamps erected, the total estimated cost of the work being £2,200.

Leamington.—In view of the favourable report made by Mr. Robert Hammond the supply of electricity in the borough is to be undertaken by the Corporation. In their provisional order there will be a clause providing for taking over that portion of the undertaking of the Midland Electric Light and Power Company, Limited, which would be of use to the Corporation.

Leeds.—A Local Government Board inquiry relative to the application of the Leeds Corporation for a provisional order to enable them to issue stock for the purchase of the undertaking of the House-to-House Electricity Company, Limited, will be held at the Town Hall on 31st inst.

Leicester.—At last week's Council meeting Alderman Lennard presented the half-yearly statement of the Electric Lighting Committee, ending December 31st, from which it appeared that the result of the working to the date named, after paying interest on capital, and £581 17s. 4d. on account of sinking fund, was a profit of £449 5s. 10d. Deducting that amount from £1,819 3s. 6d. loss to June 31st last, showed a net loss of £1,369 17s. 8d. The total amount which had been paid on account of sinking fund was £3,741 5s. 6d. The committee also reported that good progress had been made with the apparatus in connection with the works, and it was anticipated that the extension would be completed in good time to meet next season's requirements. With regard to the revenue account, their total receipts were £3,654, as against £3,068 for the corresponding half of the previous year, showing an increase of about £566. In the corresponding half they were charging 6d. per unit, while in the present balance-sheet it was 5d. per unit; that meant a loss to their revenue account of £664. On the expenditure side they had a total expenditure of £1,897, as against £1,436, an increase of £461. The total profit on the profit and loss account was £1,757 for the half-year, as against £1,631 for the corresponding half of the preceding year, so that while their business had increased something like 15 per cent. they had only a net increased profit of £126; after paying interest and sinking fund charges they only had a net profit of £449 as against £457. The net result up to date was that whereas at the end of June they stood with a debit balance on revenue account of £1,819, they now deducted £449, net profit, leaving the debit balance £1,370, and their sinking fund now stood at £3,741.

London.—The Works' Committee of the St. Luke's Vestry has recommended that the principal thoroughfares of the parish—City Road, Finsbury Pavement, Old Street, Golden Lane, &c., be electrically lighted. The matter was by consent referred back.

London County Council.—The gas plant at the Crossness outfall has become worn out and inadequate for lighting the works during next winter. The Main Drainage Committee recommends that the Council agree to the installation of electric light at the Crossness outfall in accordance with the drawings presented to the Main Drainage Committee, at an estimated cost of £7,000; and that tenders be invited for the supply and fixing complete of the dynamos, engines, switchboard, and principal mains, and also for the supply and fixing of the service mains, wiring and fittings.

Lynn.—Prof. Robinson's report estimates the cost of an electric lighting plant for the district at about £15,000.

Marylebone.—The Vestry has instructed the Special Committee to enter into negotiations for the acquisition of a site for a dust destructor and electric lighting station.

Newington.—The Vestry has decided to open a separate account with the treasurer for the electric lighting undertaking, and his offer to place £5,000 at the disposal of the Vestry pending the completion of a loan has been accepted.

Northampton.—The directors of the Northampton Electric Light and Power Company have informed the Town Council that they do not feel in a position to name a price for the sale of their undertaking.

Partick.—The Board of Trade have had under their consideration the application of the Kelvinside Company for a provisional order to light the burgh with electric lighting. The application was opposed by the Commissioners of the burgh and Glasgow Corporation, and the Board of Trade has decided not to proceed with the application.

Portsmouth.—We learn that a number of the leading tradesmen here have sent a petition to the Council against the Electric Lighting Committee's proposal to give facilities to the Free Wiring Company. We are informed by a correspondent that those interested in the local electrical trade look upon this in the light of unfair competition.

Saltburn.—The District Council is giving its consent to the Cleveland and South Durham Assets Company's application for permission to erect poles, &c., in certain streets for electric lighting.

Shoreditch.—The present cable from Great Eastern Street sub-station through Leonard Street is too small and a ·75 cable is to be at once substituted, the cost of the work being about £390. Larger cables are also to be substituted for those at present laid in Great Eastern Street, Paul Street, Curtain Road, Old Street, and other streets where the chief engineer has advised such substitution.

Southport.—A Local Government Board inquiry was held last week into an application by the Council for power to borrow £21,178 for electric lighting purposes. The electric light extensions consist of the erection of a 600-unit engine and alternator combined, the laying down of two main cables, and various other works. There has been a rapid increase in the demand for electricity, and it is estimated that the proposed extensions will meet the requirements of the town for 18 months or two years.

Spain.—Messrs. W. Baird & Co., of Glasgow, who are working the iron ore mines of the Pedroso Company in the Province of Seville, have put down an electric lighting plant at their wharf on the Guadalquiver, at Seville, in order that the loading of ore into the steamers may be carried on both day and night.

Stirling.—The Police Commissioners have asked Mr. R. F. Yorke to give them a report on the water power available at their reservoirs for the electric lighting of the town.

Sunderland.—In the new workhouse infirmary being erected for the Board of Guardians (cost £20,000) provision is to be made for installing the electric light.

Swansea.—Mr. Manville has made his report on the lighting question. The borough surveyor is reporting on dust destructors. The two reports will be discussed in committee shortly.

Tottenham.—The Tottenham and Edmonton Gas Company has withdrawn the electric lighting clauses from the Bill before Parliament.

Walsall.—The Electric Lighting Committee reports a further increase in the number of consumers, and that after paying interest on loans and providing sinking fund, there is a deficiency of £531 17s. 7d. on the past year's business, making with the previous year's loss the total deficiency on the undertaking up to December 31st last, £977 1s. 5d.

Watford.—The Board of Trade has approved of the Council's electric lighting scheme.

Withington.—The District Council on 17th inst. discussed the terms offered by the Manchester Corporation for the supply of electricity. A sub-committee from Withington will confer with the Manchester Electricity Committee.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Barking.—Mr. Crooks will bring forward at the next L.C.C. meeting a proposal to refer it to the Highways Committee to consider and report as to the practicability of the Council laying and itself working a tramway along the top of the northern outfall sewer embankment from Stratford to Barking; and also what system of traction would be the most suitable and economical for such a tramway.

Bradford.—The Tramways Committee has appointed Mr. C. F. Spencer, of Walsall, manager for the Bolton Road and Great Horton electric trams, at a salary of £150 a year.

Bristol.—The thirty-eighth ordinary general meeting of the Imperial Tramways Company was held at Bristol on Monday, and Mr. George White, the chairman, in his speech referred to the electrical prospects on several lines. The London United Tramways, Limited, was the one undertaking not actually worked by the company; they had, however, an investment in it, and it was making great strides. The Acton, Brentford, Hounslow, and Hanwell councils had all approved of the proposed new electric tramways. He was personally looking forward to very important results from the development of the United system, inasmuch as they had since received memorials from other districts adjacent to their lines begging them to apply at once for light railways to be worked by overhead electricity, and to connect up with their general system. The small tramway at Darlington, the directors were working on much the same lines as of old, but they would have to apply their minds to substituting electricity in the town also. The Middlesborough, Stockton, and Thornaby electric tramway had proceeded under the able guidance of the managing director and engineer, Mr. Clifton Robinson, and had been completed in so expeditious a manner, that he believed it formed a record piece of tramway work in the United Kingdom. He knew of no previous instance where 15 miles of the best form of concreted and forked tramway had been laid in six months. The power station was well on the way to completion. Electrical arrangements was also in an advanced state, and there could be no doubt the works would be opened in the current half-year, and when finished, would certainly be one of the most complete in this country, or indeed, he might say, in the world. The power house would be a model of its kind.

City and Brixton Electric Railway.—The Bill for the construction of this new electric railway from Brixton to the City, with stations at Brixton Hill, Lorne Road, Kennington Oval, Kennington Cross, Lambeth, St. George's Circus, and King William Street, which the City and South London Company, which will have connections at the Oval and at King William Street, have agreed to work in perpetuity, came last week before a committee of the House of Commons. Mr. Littler, Q.C., in opening the case for the promoters, said the scheme was originally threatened with considerable opposition, but the London County Council, the London, Chatham and Dover Railway Company, and the Lambeth Vestry were apparently satisfied that they would not be injuriously affected, as they were not represented by counsel. The only active opposition came, says the *Times* report, from the St. Saviour's District Board of Works, who raised points as to the depth of soil that ought to be maintained between the tunnels and the roadways, the possible interference with a lavatory, and other small matters. The construction would be carried on by the shield system which had been so successfully adopted in the case of the Central London Railway and elsewhere throughout the metropolis. He mentioned incidentally that the City and South London Company were now constructing a new tunnel under the Thames in connection with their Islington extension, and that consequently they intended to abandon their original London Bridge tunnel, which would now be available for the growth of mushrooms in the same way as the Waterloo tunnel at Edinburgh, where these succulent fungi are cultivated with considerable success. Mr. Mott, chairman of the City and South London Railway, gave evidence to the effect that there would be no difficulty in raising the capital of £1,200,000 necessary for constructing the railway, along with the stations and other incidental works. After hearing engineering evidence from Sir Benjamin Baker, the committee decided to pass the Bill, subject to the insertion of clauses which are now in course of arrangement with the St. Saviour's District Board of Works.

The City and Brixton Railway Bill, the preamble of which was passed last week, came before the Select Commons Committee on the consideration of clauses the other day. Amendments having been made to meet the objections of the local authorities, the Bill, as amended, was ordered to be reported for third reading.

In regard to Mr. Littler's statement respecting the London Bridge tunnel, the *Pall Mall* has inquired of Mr. Jenkin, the general manager of the C. and S. L., and finds that the facts are as follows:—The London Bridge tunnel forms part of the line from Stockwell to King William Street, which was opened in 1890. It is now proposed to hand over this tunnel to the new Brixton line, to bore another tunnel on the other side of London Bridge, and extend the line to Lombard Street, Moorgate Street, and then on to Islington. The deviation from the present line will be made a short distance from the Borough Station on the City side.

The same Committee also had before them the City and South London Railway Bill, which proposed to authorise the construction of sidings at Clapham, the acquisition of lands for the purposes of the company, and an extension of time in connection with the undertaking, and to empower the sale of a portion of the line to the other company—the City and Brixton. The Bill was ordered to be reported to the House.

Charing Cross and Hampstead Underground Electric Railway.—The Bill promoted by the Charing Cross, Euston and Hampstead Railway Company came before a Select Committee of the House of Commons the other day, but the threatened opposition having been withdrawn, the Bill was referred to the Unopposed Bill Committee.

Clontarf.—A successful trial trip was made on this electric tramline on 17th inst, by the contractors' representatives. Public service was commenced this week.

Coatbridge and Airdrie.—The Light Railway Commissioners will hold an inquiry at Coatbridge on Tuesday, March 29th, into the application of the British Electric Traction Company to lay a light electric railway between these two towns.

Dublin.—The Dublin United Tramways Company have lodged a memorial with the Lord Lieutenant for an Order in Council authorising the extension and doubling of the lines of their system in various districts in the city. The total proposed expenditure amounts to £74,858.

Dudley.—A special meeting of the Town Council was held on Tuesday for the purpose of again considering the tramways question which has been engaging their attention for some time. It may be remembered that the Council opposed the scheme of the British Electric Traction Company when the Light Railway Commission sat at Dudley, because the Council desired to have the tramways in their own hands. The tramway which has given rise to the discussion is the portion of the Dudley and Stourbridge line that runs from Dudley Station to the borough boundary at Hart's Hill; but it is proposed to construct a new line from Queen's Cross, at Dudley, to Bishton's Bridge, at Netherton, that will tap the thickly populated district of Netherton, and provide a means for the Old Hill and Cradley Heath people getting to Dudley. These are the tramways within the borough at the present time. The British Electric Traction Company have an order to construct a line from a place called the "Deck Hole," Dudley, to Kingswinford, and thence to Stourbridge, and the company will also have the portion of the Dudley and Stourbridge line from Hart's Hill to Stourbridge. Whether the British Electric Traction Company should have the whole tramway section has been a subject keenly discussed. The Council have consulted Mr. Reginald P. Wilson, and his report has been submitted to the Council. He strongly recommends the Council to acquire the portion of the Dudley and Stourbridge line to Hart's Hill, and the construction of the new line to Netherton. He considers there are some thousands of pounds of profit in it to the town if electric traction is employed. Using the very best rails, and constructing the line on the best methods, he estimates that the cost of putting the Hart's Hill track in order for electric traction will be £13,150, and the cost of constructing the new line to Netherton at £11,452. He estimates the total capital expenditure to be £50,000, and after allowing for interest and sinking fund, he is of opinion that there will be a net profit of nearly £4,000 per annum, providing that the cost of current is at 2½d. per unit. If the Council should first acquire the tramways, and then agree to lease them to an outside company, then he suggests that the company should pay 2½d. per unit for the electric power, 5½ per cent. on the capital expended, and 15 per cent. on all tickets sold over the Council's sections of the lines. Even then, he thinks, the company would make the handsome profit of not less than £2,300 on a capital of less than £10,000. The Light Railway Commissioners being in favour of giving to the British Electric Traction Company the right to construct the line to Cradley Heath, and the Council having preserved the right of appeal to the Board of Trade, he advises the Council to oppose the decision of the Commissioners before the Board of Trade. The Council has passed a series of resolutions to the effect that Mr. Wilson's report be adopted; that the Council should construct, and as soon as circumstances allow, electrically equip the branch tramway or light railway to Cradley, with the consent of the Rowley District Council, or, in case that authority should object, to the boundary of the borough in that direction, that the Council oppose the application of the British Electric Traction Company for powers to construct the branch line above mentioned; that the Corporation electric lighting scheme be carried out without delay. The Railway, Tramway and Electric Lighting Committee will carry matters through. This means that the Dudley tramways scheme is to be municipalised, and the initial expenditure is estimated at £50,000.

The Finchley Electric Line Rejected.—The Light Railway Commissioners resumed and concluded last Saturday, at the Hampstead Vestry Hall, a three days' public inquiry into the scheme for connecting Finchley and Hendon with Hampstead by means of an electric tramway. We have already mentioned that there was a determined opposition from the local authorities. The promoters were Mr. J. T. Firbank, M.P., and Mr. Murphy, and the engineers Sir Douglas Fox and Mr. Wragg. In the result the Commissioners said that the necessity for the "light railway" had not been proved, and they therefore declined to grant an order for its construction.

Great Orme.—The unopposed Bill for the construction of a tramway from Llandudno up the Great Orme was before the House of Commons Committee last week. The line would be about a mile long and would cost £20,000.

Halifax.—Major Cardew has been holding a Board of Trade inquiry respecting an application by the Corporation to borrow £20,000 for electric tramway purposes.

The two routes of tramways which are in course of construction will, it is expected, be opened for traffic at Whitsuntide.

Hastings.—The borough engineer has presented a very lengthy report on the tramways question, in which he states that after obtaining information from numerous towns regarding systems, he has come to the conclusion that the overhead electric trolley system is the most suitable for Hastings. Routes are suggested and general considerations are discussed. Single lines, 3 feet 6 inches gauge, with frequent passing places, are recommended. The lines would be 2 miles 1 furlong and 2 miles 7 furlongs long. The cost of construction is given as £7,263 per mile, and the cost of working £6,356 per annum; income £8,424. The committee recommended that the various suggestions made as to the construction and working by the Corporation of the two main lines be adopted; that power be also sought to construct and work the branch lines suggested; that the overhead electric system of traction be used throughout, and that a special committee of seven members be appointed to determine and carry out the details of the scheme. These recommendations have been adopted by the Council, and a special meeting of the Council is to be held on April 20th next.

Ilkeston.—The Council (sitting as General Purposes Committee) has passed a resolution in favour of tramways for the borough, steps to be taken by the Council in that direction. The Town Clerk is to collect details as to the working of tramways at Dover and elsewhere.

Leicester.—The Town Council has appointed a special committee to consider the advisability of purchasing the tramways, and also to report on a suitable system of traction.

Manchester Underground "Electric."—A *Manchester City News* writer has seen plans of an underground electric railway for Manchester, "which only await the capitalist in order to be carried out." The first part of the scheme is to connect the various railway stations by means of an inner circle in the city—a length of 3½ miles. The second part of the scheme would be an outer circle 8 miles in length.

The Metropolitan Underground.—The Great Western Railway Company, which runs 17 trains per day over a part of the lines of the Metropolitan, has raised objection to the Bill applied for by the company authorising electrical equipment. The objections came before the Court of Referees at the House of Commons on Monday. The Great Western trains running on the line are necessarily subject to the Metropolitan Company's approval, and the Great Western appears to think that when the line is electrically equipped they also may be compelled to change their system to electricity.

Paisley.—The British Electric Traction Company, which has made a conditional agreement with the Paisley Tramways Company, has laid its proposals before the Town Council. It is proposed to extend in the direction of Johnstone in the west, Glasgow boundary in the east, Renfrew in the north, and Potterhill in the south, electricity being, of course, employed. A lease of at least 28 years is suggested, and the company offers to negotiate for the supply of electrical energy from the Corporation works when put down. Mr. Teague has the letter in hand for report. The tramways company transfers its undertaking as at January 1st, 1898, the price being £18,591 odd.

Plymouth.—The Plymouth Corporation will oppose the Devonport, Plymouth, and Stoke Tramways Bill.

Riesengebirge.—The whole Silesian slope of the Riesengebirge, including the Upper Iser, belongs to the Warmbrunner line of the Schaffgotsch. The managers of this property have decided, as much in their own interest as in that of the tourist, to consider the question of opening up the Riesengebirge by a Kamm railway and a Schneekoppe railway. The building of the lines will commence as soon as possible, and it has been decided to work them by electricity. The immense energy of the larger streams, which descend the Riesengebirge, is to be utilised for generating the electricity, and in two or three years a network of light electric railways will render all important points of the Riesengebirge accessible; at the same time, the exploitation of the vast forest lands will be facilitated by this system of railways, which will be an immense improvement on previous methods of transport. The new network of railways will be connected to existing lines at six points; in the west at Warmbrunn, Hermsdorf and Petersdorf, and in the east at Schmiedeberg, Arnsdorf and Krummhübel. The Koppe and Kamm line will connect on to the branch line, Tillerthat, Krummhübel, mount in bold curves, past Quersiffen, to Brotbaude, run past the highest houses on the beautiful Brückenberg, to Kirche Wang, then wind past the Schlingelbaude and the "Eyes of the Mountain" to Hamppelbaude, and, finally, in serpentine windings, mount the last slope of the Kamm, and reach a station near the Reisenbaude. From this the line will run round the steep Schuttkogel of the Schneekoppe, in a double spiral, up to the Koppe houses. May we be spared this trip!

St. Helen's.—Having regard to the changes to take place in the immediate future in the method of traction, in the character of the service generally, and the consequent outlay required by the company, no dividend is to be paid by the St. Helen's Tramway Company for the last half-year.

Whitley and North Shields.—It is proposed by the British Electric Traction Company, Limited, which has lately taken over the North Shields and Tynemouth tramways, to build a light electric railway along the coast road between Whitley, Tynemouth and North Shields.

TELEGRAPH AND TELEPHONE NOTES.

Cable Communication to Australia.—According to a *Pall Mall Gazette* correspondent "A Departmental Committee, including representatives of the Colonial Office, the War Office, the Admiralty, and the Colonies, is now sitting under the presidency of Sir William James Lloyd Wharton, K.C.B., Hydrographer of the Navy, to consider the proposal of the Eastern Telegraph Company to lay an all-British cable connecting London with the Cape, Natal, Mauritius, and Australia, as an alternative scheme to the proposed Pacific cable from Vancouver to Australia and New Zealand. The Imperial representatives regard the two lines chiefly from the strategic standpoint, and it is understood that there is almost a consensus of opinion in favour of the Cape-Australian scheme, especially if a connection be established with India and Ceylon. There is a division of opinion in the Australasian colonies, the eastern provinces favouring the Pacific project as supplying an entirely new line with extensive commercial possibilities in the near future, and the western colonies being more in sympathy with establishing a direct connection with South Africa and the Mauritius. The cable companies require an extension of the existing subsidy of £32,500 a year for a fresh term of years in the event of their incurring the very considerable cost of constructing the new line. New Zealand, as well as the eastern colonies of Australia, object to this guarantee, and would prefer that any fresh financial responsibilities should be in connection with a trans-Pacific route. It is doubtful, however, if the Imperial Government will be disposed to contribute a third of the cost of that line at present. Hence it may be somewhat difficult to reconcile the conflict of interests."

The Iceland Cable.—In regard to the scheme of the Iceland Cable Company the *Standard* remarks that the Danish Government is willing to guarantee £5,000 a year for 20 years, and the British Government is to be asked to guarantee £3,000 a year for a similar period. Mr. Doughty, the member for Grimsby, intends to bring the question before the attention of Parliament; and it is also to be discussed at a meeting of the Sea Fisheries Association, at the Fishmongers' Hall, on March 31st. It is expected that the Government will show some unwillingness to subsidise a foreign company.

Interruption of the Cape Cables.—We have again to add to the long list of interruptions and delays which have occurred from time to time in the telegraph communication with the Cape. On the 17th current we were officially informed by the Berne Office that "the St. Thomé-Loanda cable will be interrupted intermittingly during the next three or four days for renewal purposes, traffic will be forwarded by the East or West Coast routes when necessary, without alteration of rates." Two days later we heard from the same source that the Lorenzo-Marques-Durban cable was interrupted, that the repairs to the St. Thomé-Loanda cable were not yet completed, but "communication with South Africa is maintained by the Portuguese landlines from Lorenso Marques to Transvaal." It will thus be seen that both the East and West Coast routes were interrupted, and our communication with Cape Town was entirely depending on the some 1,000 miles of landline, the greater part of which passes through foreign territory. Although this state of affairs did not last long, for later in the day the St. Thomé-Loanda cable was repaired (thus restoring the West Coast route), it proves once more the absolute necessity of laying another cable to the Cape, and, as we have previously pointed out, the cable company who is, and has been since its existence, in receipt of large subsidies from the English, Cape of Good Hope, Natal and Portuguese Governments, should be quite able to carry out the work without further "privileges" for doing so.

Interruptions to Australian Landlines.—Referring to the list of interruptions to the Australian trunk landlines recently published by us, we are able to furnish our readers, from Australian papers just to hand, with a little more information on the subject, and the following extracts from the Australian press will show that there is every cause for the general dissatisfaction which has been expressed, both in England and Australia, with the existing system of telegraphic communication between the great commercial centres of both countries:—

February 8th.—"The Postmaster-General, Adelaide, advises:—'Port Darwin line still interrupted. Our West Australian lines are working badly owing to thunderstorms. Very little prospect of getting cable business through.'"

No cablegrams from London were received in Sydney on February 8th.

February 10th.—"The Postmaster-General at Adelaide advises:—'The Port Darwin line is interrupted north of Woodnadatta since 11.30 p.m., Wednesday. Probably caused by floods.'"

No cablegrams from Europe were published in Sydney on February 11th, so we presume that the West Australian line was also interrupted.

February 11th.—"Adelaide. The Postmaster-General reported this morning: —'Fault removed between Oodnadatta and Charlotte Waters, 9.5 a.m. Line still interrupted between Barlow and Tennant's Creeks since 5.35 p.m. yesterday.'"

Later.—"Communication restored Port Darwin line at 2.15 p.m."

In the same paper we read:—"Port Darwin, Friday, February 11th:—'The Cable Company's steamer *Recorder* has been here for some days past repairing the cable.'"

February 14th.—"Perth, Saturday (February 12th). Great dissatisfaction is expressed here at the unsatisfactory working of the Inter-Colonial Telegraph line on the South Australian side. Many messages are 24 hours late, and there is great difficulty in obtaining share quotations. The local exchanges are completely paralysed. For several nights lately the lines have failed altogether, or else worked very badly."

It will be seen that the scanty information we are able to make known is only gathered from such particulars as appear from time to time in the Australian press. As we have frequently pointed out, it is seldom, if ever, that any notice of interruption to the Australian trunk landlines is furnished by the Bureau International des Administrations Télégraphiques. It will be noticed that what information is published in Australia emanates from Sir Charles Todd, the Postmaster-General of South Australia, yet that gentleman, in answering a protest from the London Chamber of Commerce towards the end of last year concerning the delays in the transmission of cable messages to and from South Australia, says that "delays have rarely occurred," and that he does not "anticipate any further complaints." We do not see how that statement can be reconciled with the following extracts from letters in the Australian papers we are now dealing with:—

"During the past six or seven months the interruptions of the overland telegraph line to Port Darwin have been sufficiently frequent to cause very serious inconvenience to business people. On every such occasion the utter worthlessness of the Roebuck Bay line as an emergency one has been fully demonstrated. It would therefore seem that the Eastern colonies must look to a Pacific cable if they desire an alternative service of any value, and free from the misleading information supplied too frequently from Adelaide."

Another writer says:

"The increasing frequency of the interruptions to the cable service to Europe, both as regards the submarine system and the landlines, would, one might imagine, be sufficient to draw serious attention to the faultiness of the present means of communication much more strongly than it appears to. To many business men it must mean immense loss."

In commenting on Sir Charles Todd's reply to the secretary of the London Chamber of Commerce, the writer continues:—

"If delays are occasionally due to heavy business, it is clear that the lines are insufficient for the purpose for which they are designed, and therefore should have their carrying powers increased. When the West Australian landline was connected from Roebuck to Adelaide, it was intended as an attempt in this direction; but it has proved utterly unreliable, being more often out of order than not."

The same correspondent goes on to show that an alternative line for telegraphic communication between England and Australia is a necessity, and says:—

"Such a route would be offered by the Pacific cable. In the event of war being declared, the Pacific cable would in all probability be worth many times the sum we seem so reluctant to grant, even if it only remained open sufficiently long to give us warning."

We have for years advocated the laying of the Pacific cable, so that the principal centres of population in Australasia might be entirely independent of the two unreliable lines which run across that vast continent to meet the submarine cables; besides which it would be invaluable for strategic purposes, and we trust, that now the Australian Governments are reported as willing to take action in this direction, some definite movement may soon be made.

The Telephone Service.—In the Commons last week, Sir Mark Stewart asked the Secretary to the Treasury, as representing the Postmaster-General, whether it was the practice of the Post Office to substitute a telephone for a telegraph where the guarantors have signed an agreement with the Post Office for a telegraph service; and if it were so, would he state the reasons. Mr. Hanbury, in reply, said it has been judicially decided that the definition of telegraph includes a telephone. In agreements of the kind referred to there is no provision as to the particular form of instrument to be used. The guarantee for a telegraph extension is based on the most suitable method of serving the office, and if a telephone is used it is because it offers advantages over other forms of telegraph apparatus, either in regard to initial cost, maintenance, or working.

The Association of Chambers of Commerce meeting in London last week, passed a resolution pressing upon the Telegraph Department of the Government the necessity of promptly increasing the telephone trunk line service between mercantile centres.

The Huddersfield Corporation has had a discussion *re* telephone matters, particularly regarding rates. The Telephone Company is substituting underground for overhead wires, and reconstructing the plant on the twin-wire system. The North Staffordshire Chamber of Commerce has also been discussing the inefficiency of the service and the high charges. Mr. Gaine and Mr. Coleman met the Chamber the other day, and it was explained that there was no prospect of reduced charges, as the plant was to be constructed on the twin-wire system in order to improve the service.

The Pacific Cable.—The British Empire League meeting at Ottawa on 10th inst., passed a long resolution regarding the Pacific cable scheme, urging the Government and Parliament of Canada to continue such action as may be necessary to secure the early commencement of the cable. A committee was appointed consisting of Sir Sandford Fleming, Colonel Denison, Messrs Casey, M.P., Hughes, M.P., and Principal Grant, to wait upon the Government for the purpose of presenting the resolution and urging prompt action.

The Telegraph Clerks.—The London committee of the Postal Telegraph Clerks' Association issued last week a statement in reply to the circular of March 15th issued by the Postmaster-General. The association states that many points are not yet dealt with, and pressing grievances remain unredressed. As examples they particularly draw attention to two points—classification and holidays.

FORTHCOMING EVENTS.

1898.

Friday, March 25th, at 8 p.m.—The Institution of Civil Engineers (students' meeting). "Internal Governor Friction," by H. O. Eurich, Stud.Inst.C.E.

At 5 p.m.—Physical Society at the rooms of the Chemical Society, Burlington House. (1) "On the Circulation of the Residual Gaseous Matter in a Crookes Tube," by Mr. A. A. Campbell Swinton. (2) "On some Improvements in the Roberts-Austen Recording Pyrometer, and Notes on Thermo-electric Pyrometers," by Mr. A. Stansfield.

At 8 p.m.—Electro-Harmonic Society. Last Smoking Concert of the season at St. James's Hall Restaurant.

Monday, March 28th. Last day for Darwen Corporation electric light plant tenders.

Wednesday, March 30th, at 8 p.m.—Society of Arts. Prof. S. P. Thompson, on "Telegraphy Across Space." Mr. J. W. Swan, F.R.S., will preside.

Royal United Service Institution. Captain J. N. C. Kennedy on "Wireless Telegraphy."

At 7.30 p.m.—Institution of Electrical Engineers. Students' meeting. Paper on "Electrical Instruments," by M. R. Gardner, Student.

Thursday, March 31st.—Last day for Hampstead extension plant tenders.

Royal Institution of Great Britain. Prof. J. A. Fleming, M.A., D.Sc., F.R.S., M.R.I., on "Recent Researches in Magnetism and Dia-magnetism." (Lecture V.).

At 3 p.m.—Chemical Society, Burlington House. Annual general meeting.

Friday, April 1st, 8 p.m.—Institution of Junior Engineers at the Westminster Palace Hotel. Paper on "Mechanical Refrigeration," by Mr. J. T. Burrell, of Peterborough.

Saturday, April 2nd, 11 a.m.—Visit of the Institution of Junior Engineers to the Thames Iron Works, Blackwall.

Tuesday, April 5th, at 8 p.m.—Röntgen Society, at 11, Chandos Street, Cavendish Square, W. Paper by Mr. James Wimshurst upon "The Influence Machine and its Advantages for lighting X-Ray Tubes."

CONTRACTS OPEN AND CLOSED.

OPEN.

Ashton-under-Lyne. — April 5th. The Corporation invites tenders from firms willing to undertake the free wiring of premises in the Borough. Consulting engineers, Messrs. Lacey, Clirehugh & Sillar, 78, King Street, Manchester. See our "Official Notices."

Belgium.—March 30th. Tenders are being invited by the municipal authorities of Ghent for the supply and erection, &c., of a complete installation for the electric lighting of the town dock. Particulars may be obtained from, and tenders to be sent to, l'Hotel de Ville, Ghent, Belgium.

Belgium.—April 1st. The Municipal Authorities of Seraing are inviting tenders for the concession for the supply of electrical energy in the town for public and private lighting purposes during a period of 30 years. Particulars may be had from, and tenders to be sent to, the College des Bourgmestre et Echevins, Seraing, Belgium.

Bournemouth.—The Corporation wants tenders for the electric lighting of the pier and pleasure grounds. Particulars *re* plant, &c., are given in our "Official Notices" March 18th. Borough engineer, Mr. F. W. Lacey.

Bournemouth.—April 4th. The Corporation wants tenders for motor vehicles for the collection of house refuse, &c. Borough engineer, Mr. F. W. Lacey. See our "Official Notices" March 18th.

Darwen.—March 28th. The Corporation wants tenders for the supply of steam engine and dynamos, piping, accumulators, switchboards, mains, arc lamps, pillars, &c. See our "Official Notices" March 11th.

Denmark.—March 30th. Tenders are being invited until the 30th inst. by the Danish Telegraph Department in Copenhagen for the supply of 56 tons of copper-bronze wire, 4 mm. diameter, and 42 tons of copper-bronze wire, 3½ mm. diameter. Particulars may be obtained from, and tenders to be sent to, Die Telegraf-directorale Tekniske-afdeling, Copenhagen.

Derby.—April 12th. The Corporation wants tenders for the electric wiring of its Ford Street yard and premises. See our "Official Notices" March 18th.

Derby.—April 11th. The School Board want tenders for the electric wiring of the Traffic Street Board School, Derby. Particulars from Mr. J. E. Stewart, Corporation electrical engineer. See our "Official Notices" last week.

France.—March 30th. Tenders are being invited by the municipal authorities of Paris for the supply of the electrical conductors, required in connection with the electric lighting of the Square Vaugirard. Particulars may be had on application, and tenders to be sent to, l'Hotel de Ville, Paris.

France.—March 31st. Tenders are being invited by the Municipal Authorities of Saint Chamond (Loire) for the concession for the lighting of the public streets of the town, either by gas or electricity. Particulars from, and tenders to be sent to, La Mairie de Saint Chamond (Loire).

Hampstead.—March 31st. The Vestry wants tenders for the supply and erection of one or two steam alternators, switchboard panels, two induced draught wet back boilers, feed water heater, steam and exhaust pipes, feed pumps, 50 kw. exciter, and a feed water softener. See our "Official Notices" March 18th for full particulars.

Leyton.—April 4th. The District Council wants tenders for the supply of two dynamos, one transformer, two gas engines and connections, and switchboards for extension of the electricity works. Electrical engineer, Mr. H. C. Bishop. See our "Official Notices" March 18th.

Manchester.—April 4th. The Lancashire and Yorkshire Railway Company is inviting tenders for various stores. The following are a few of the items:—5. Copper; 7. Copper tubes for boilers; 8. Copper tubing; 29. Signal and telegraph fittings; 30. Signal, telegraph and electric light wires. Samples may be seen and forms of tender and further particulars obtained at the Stores Department, Osborne Street, Manchester.

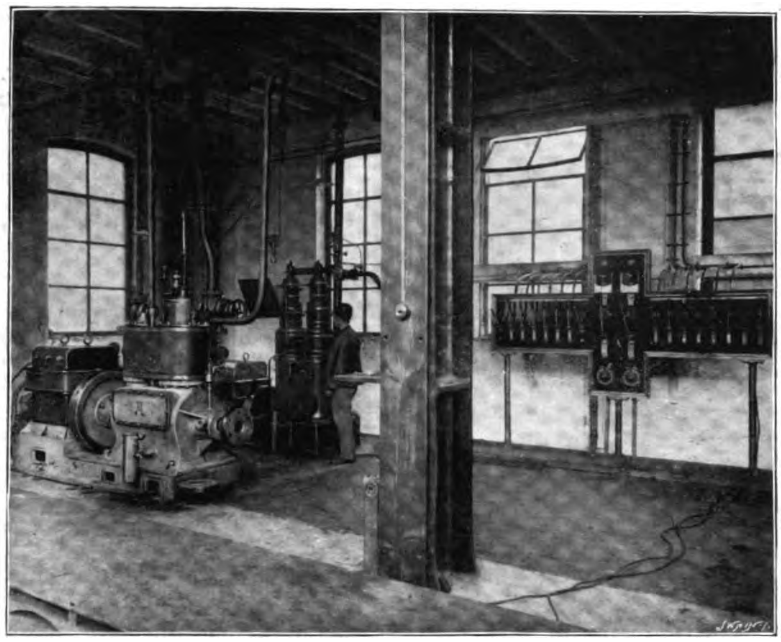
Shoreditch.—April 12th. The Vestry want tenders for the supply and erection of arc lamps and accessories, also for electric cable. Electrical engineer, Mr. C. N. Russell. See our "Official Notices" this week.

(*Continued on page* 409.)

MESSRS. MAVOR & COULSON'S WORKS, GLASGOW.

THE new works of Messrs. Mavor & Coulson, Limited, have been recently opened, and as they are equipped with the most modern plant some details of them may be interesting. The works are erected on ground purchased by the company from Messrs. Clark & Co., Limited, who formerly used the site for their Mile End Thread Works. The works are $1\frac{1}{2}$ miles distant from Glasgow Royal Exchange, and are within three minutes' walk of the Bridgeton Cross Stations of the North British and Caledonian Railways.

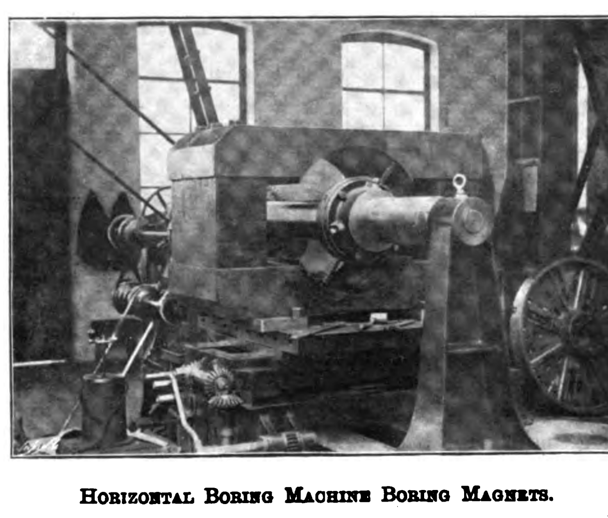
The company's manufacturing business was formerly carried on in their premises in Orr Street, Bridgeton, which premises together with the machine tools there were held on lease. During the company's tenancy of these works patterns were developed and standardised, and methods of production systematised. At the expiry of their lease last year the company was therefore in a singularly favourable position to undertake the design and equipment of a new factory for their specialities in electrical machinery and accessories. In the general arrangement of the works and selection of machinery, the directors have had the advantage of an intimate knowledge of the most recent American and Continental practice, and of their own special requirements. The result has been the building and equipping of a factory, which is the only one of its kind in Scotland, which provides facilities for the rapid, economical, and accurate production of high-class electrical machinery, and is probably not surpassed by the best and most recent factories in the country. The establishment of this new factory for the extensive manufacture of electrical plant in Glasgow is an important addition to the long and varied list of industries which have been located in and around the city.



GENERATING PLANT FOR SHOP DRIVING.

The existing buildings formerly used for the thread factory and stores have been partially utilised for the new factory. The ground formerly occupied by the engine and boiler house, wood stores, bobbin shop, packing case warehouse, &c., has been cleared, and a spacious new shop and smithy, brass foundry and moulding shop have been erected. The machine shop is 160 feet long by 75 feet wide, and is covered by a single span steel roof, glazed all over and supported by 14-inch brick walls, and cast-iron columns carrying the crane girders which are spaced at 40 foot centres. The lofty roof gives a spacious and airy workshop, while its steel and glass structure and the side windows in the walls provide exceptionally good and uniform lighting. The heating is effected by cast-iron pipes supplied with exhaust steam from the engines. On either side of the space swept by the crane is erected a gallery, which will be used on the one side by the pattern making and carpentry department, and on the other by the store department for finished stock. The design is to ultimately use these galleries for light machine tools, and accommodate elsewhere the two departments mentioned. The large centre bay is floored with granolithic, and the two side bays under the galleries are floored with double pine planking laid on joists. The machinery in this department is driven by 10 electric motors. None of the shafting is driven direct from the steam engine, with the exception of a short length on the testing engine. It is hardly necessary to point out the advantages gained by the use of electric motors in this department.

A special feature in this department is the extensive use of milling machines and other special appliances for labour saving. While special appliances do not in any sense dispense with the necessity for skill on the part of the workman, they permit of the use of a class of labour more easily available than that of a fully trained and equipped all round tradesman. The machines and tools are arranged with a view to the utmost accuracy in work without the necessity for individual measurements by the operator, the machines themselves being provided with measuring devices in which dimensions can be read off with ease and accuracy down to $\frac{1}{1000}$th of an inch. The use of such machinery necessitates a separate department, with special appliances for making new tools and for keeping the working tools in order. This is provided in the tool room in the north-west corner of the main shop, where a staff of skilled men are constantly employed in these operations. The antiquated practice of keeping a machine standing while the operator is grinding his tools or awaiting their formation by the tool smith is thus entirely abolished. It is found that the use of highly finished and accurately made machinery is a valuable education to the men operating it. The tendency being to assimilate the character of the work produced to that of the machinery producing it, and to keep the shop and all its surroundings up to a high standard of cleanliness and order. These tendencies inevitably reflect their characteristics upon the finished product.

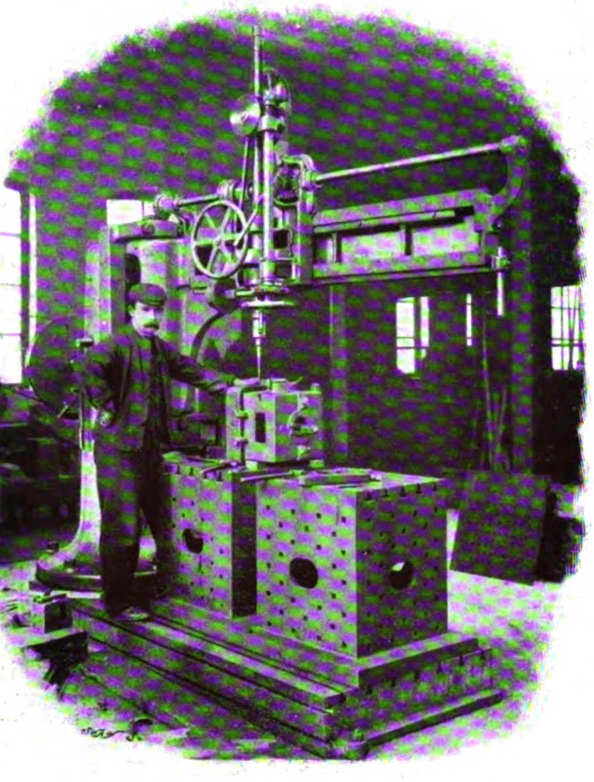


HORIZONTAL BORING MACHINE BORING MAGNETS.

The electric crane, which sweeps the whole of the centre bay of the shop, is capable of lifting about 10 tons, and can traverse the whole length of the shop from start to stop in one minute. It is fitted with a motor for each motion, and is controlled by a man who sits in a cage under one end of the crane girder. The controlling gear consists of three liquid switches, which give command over all the required motions, and which enable the driver to operate any motion at any speed, either simultaneously or independently of the

E

other motions. The entire absence of reversing clutches and other complicated mechanism renders the crane exceedingly easy to manipulate. An ordinary mechanical labourer



Radial Drill.

after one day's instruction can readily handle the crane, and expertness is soon acquired. The power required to work this crane is insignificant as compared with that required for square shafting or rope-driven cranes, and the power is only absorbed for actual work; there are no "stand-by" losses. The electric current is carried to the crane by a No. 4 copper wire, supported on insulators attached to the main girder on the east side of the shop. A rubbing contact attached to the cage picks up the current from this conductor, whence it is led by cables to the controlling switches. The crane girders themselves are fitted with conductors for carrying the current to the hoisting and across traverse motors, the current being picked up by rubbing contacts on the crab. The long traverse is driven by a light spur gear, and the cross and hoisting by special wormgears running in oil boxes.

Entering from the fitting shop is the smithy and boiler-house. In the smithy is fitted one 3-cwt. steam hammer and three forges, the forge blower being driven by an electric motor.

The brass shop occupies the ground floor of the portion of the building facing King Street. It is fitted out with turret lathes, milling machines, multiple drills, &c., for the production of large quantities of brasswork for use on switchboards, and on the various appliances connected with the wiring and installation of electric light and power. In this department, as in the machinery shop, advantage has been largely taken of the most modern improvements in American machine design, and the result is an immense improvement in the economy and accuracy of the product.

The winding shop is accomodated in the same building as the brass shop, but on the upper floor. Into this department are delivered the armature cores and magnet formers to be wound with copper conductors. There is little machinery in this department, the greater part of the work being performed by hand. The magnet wire is wound on the formers on a group of lathes driven by an electric motor. A light overhead travelling crane, operated by hand, is provided for handling parts in process of manufacture. It is capable of lifting two tons, and sweeps the whole length of the shop. After completion of the winding the armatures and magnet coils are lodged in a drying stove until the moisture is thoroughly expelled from the insulating materials. This stove is situated over specially constructed flues between the main boilers and the chimney.

In the machine shop are also placed the steam boilers, engines and dynamos for the production of electric current for lighting the works and driving the machinery. The electric lighting installation for the works and offices consists of 230 16-C.P. lamps, 30 Sunbeam 150-C.P. lamps, and six arc lamps of 2,000-C.P. each. There are in all 15 motors, of 85 aggregate horse-power. Two boilers generate steam at 160 lbs. pressure. The smaller boiler is just capable of overtaking the present work, but a Babcock & Wilcox boiler, evaporating 2,280 lbs. of water per hour, has been recently added to provide for extensions. The electric current is generated by two dynamos, each mounted on the same bed-plate with and coupled direct to a high speed single acting engine. The output of each combined set is 40 electrical horse-power. From the steam dynamos the conductors are led to the main switchboard, from which point the whole of the distribution is carried out on the company's well-known "C.C." Concentric System of wiring, in which the positive or live conductor is entirely enclosed in the negative conductor, which is uninsulated and connected to "earth." The lighting and power are supplied from the same system, but on different circuits. Each circuit is controlled by a switch on the main switchboard, on which are also placed ammeters and voltmeters to indicate the amount of power being used at any instant. Adjoining the steam dynamos is the testing table, on which all machines are temporarily run before being despatched.

Test Room.

In the brass foundry, which forms another department, are made all the brass and a few light iron castings required for the various manufactures carried out in the works. It is provided with six moulding furnaces and a core drying oven. For cleaning and cutting off the castings a group of cutting-off saws, emery grinders, and scratch brushes are driven by a $4\frac{1}{2}$ horse-power electric motor, coupled direct to a short counter-shaft. A "Cyclone" dust collector with fan driven by a motor is arranged to draw the dust from the emery grinders and deposit it in a receiver. The men are thus saved from breathing the metallic particles, and the metal is saved for re-melting. Plate moulding has been recently introduced to this department with very successful results.

While the excellence of the manufactures has secured for the company a large share of English and foreign work, and important contracts for Government departments, municipalities, and public bodies, the directors, in the design and equipment of the new factory, have kept prominently in view the large and increasing demand for electric machinery, especially for power purposes, in this district. The directors believe that there is no more promising field in the whole world for the introduction of the applications of electricity to industrial purposes than that embraced by a circle of 10 miles' radius round the city of Glasgow, and they are of opinion that the existence of these works in Glasgow will give an important stimulus to the adoption of electrical plant in Scottish industries.

THE RELATIONS BETWEEN CUSTOMER, ENGINEER AND MANUFACTURER.

In continuation of this subject, on which we published a leading article in our issue of February 11th, Mr. S. Dana Greene considers the tests and guarantees prescribed in specifications. Tests may be classed under the few heads of efficiency, heating, regulation, sparking, and insulation—he is speaking, of course, of electrical machinery particularly, and is of opinion that there should be standard tests which would simplify matters all round. Such uniform tests, moreover, would place a consulting engineer in a very strong position, for his duty would simply be to see a certain standard worked up to, and he would not then be exposed to the possibility of having to withdraw or alter unworkable clauses of his own drawing up. He advises, for America, that such standards should be drawn up by the Institute of Electrical Engineers, and why should not the same duty be undertaken by the English Institute for England. Frequently there are misconceptions as to the proper definition of efficiency—commercial or electrical. The former alone interests the customer, and for want of the proper understanding of this, we may see huge extravagancies in all sorts of practice.

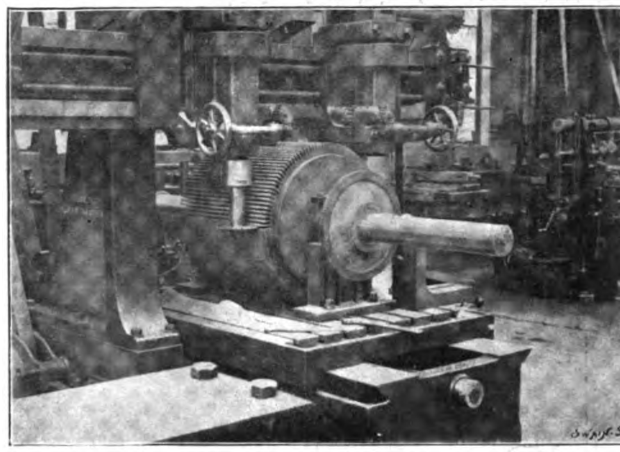
Thus, as recently pointed out by Mr. Raworth, the pursuit of the item of small fuel consumption per I.H.P. may have caused Lancashire mill owners to overlook an economy of first cost which would have been better appreciated if brake horse-power had been the datum line.

All electrical manufacturers have their own figures for the difference between carbon and copper brushes in efficiency and between different voltages, and so on, and it ought not to be difficult to form intelligent general rules.

Mr. Greene objects to the demand made upon the electrical manufacturer to guarantee the combined efficiency of engine and dynamo. Overload guarantees are sometimes required, ranging from 25 to 100 per cent. This often means increasing the capacity of a machine as surely as if it had been asked for in the specifications. Unreasonable demands for overload amount to an attempt to buy big machines at the price of small ones.

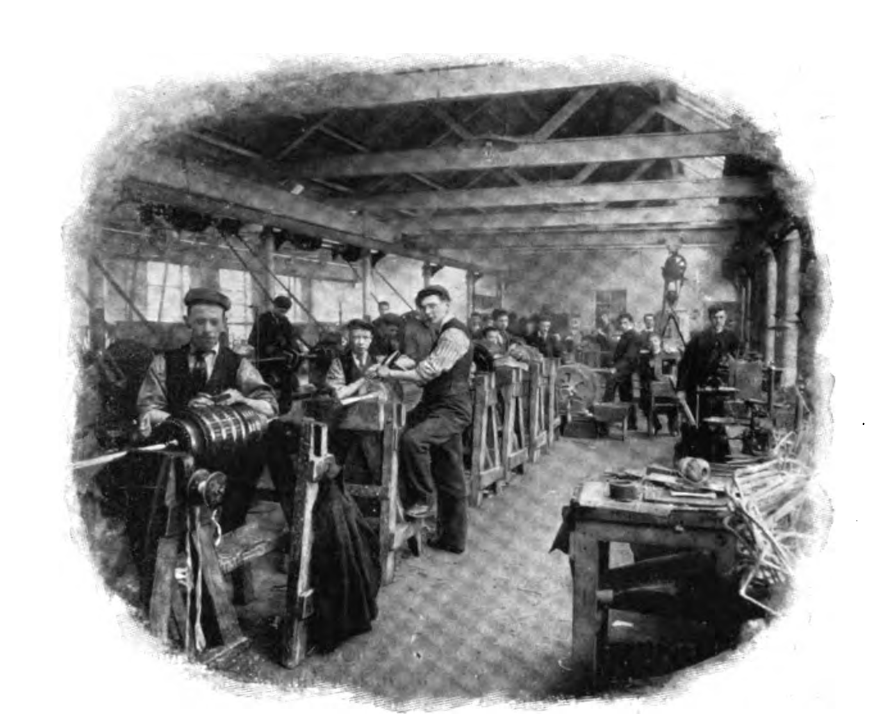
Impossible demands often specified are the straight line compounding curve, practically unattainable until we discover a magnetic material with a straight line saturation curve and a drop of 2 per cent. in speed of lighting generators not to affect the E.M.F. more than 2 volts, also impossible even with separate exciting.

In testing for insulation, because a 5,000-volt test is correct for a 1,000-volt machine, it does not follow that a 10,000-volt machine should be tested to 50,000 volts. The



Mavor & Coulson's.—Duplex Milling Machine Slotting Armature Cores.

proper method is to consider jointly the duration of test, current frequency, and voltage. As the latter rises, the margin between it and the test voltage necessarily decreases, because of the risk of injury to insulation from excessive voltage. All these things might properly be standardised, and excessively drawn specifications, leading to distorted designs and special apparatus, put a load on the customer's purse in the long run, for manufacturers do not for ever work at a loss, and the eccentric engineer becomes shunned by the best manufacturers, and is generally looked on with suspicion.



Mavor & Coulson's.—Armature Winding Shops.

Often a contractor, working for a penalty date, and paying expensive overtime, finds himself with the stuff on his hands for weeks after it should have been paid for. This sort of thing is very unfair. It is bad for workmen who have been pushing a job, to see their finished work lying ready for shipment for weeks. They invariably let the fact influence them when the next push job comes to hand, and the demoralisation perhaps makes a really urgent job late. Where there is a penalty for delay, it is urged there should be a bonus for prompt readiness to date. Again, the self-appointment of a consulting engineer as sole judge, is considered unfair; and though probably it could not be enforced at law, there ought to be provision for a third party.

Generally, Mr. Greene's paper was suggestive, and met the cordial approval of his hearers, who invite the American Institute of Electrical Engineers to consider some comprehensive plan for such standardisation of apparatus for electric light and power.

Writing on the other side of the question from that taken by Mr. Greene, Mr. White-Fraser looks on the consulting engineer as a safeguard to the honourable manufacturer—protecting him from the unscrupulous maker of inferior goods. Mr. Fraser also rather deprecates standardising as likely to hinder engineering progress. But Mr. Fraser writes as though Mr. Greene had asked for the abolition of the consulting engineer, for he refers to alternate and direct current machinery, and the pushing of one or the other by the manufacturer, where the consulting engineer would, unbiassed, be able to advise which was the better system. But Mr. Greene did not wish to abolish the engineer so much as to curb him, and restrain the tendency to design new plant when equally good things are to be bought in open market. It is in selecting systems that the value of the consultant should come in; in giving out orders that his knowledge of manufacturers should prove valuable; in passing work as sound, that his technical knowledge should avail him. There is indeed plenty for him to do in applying his knowledge and making general arrangements. As we write these lines we have in mind a large pair of steam engines which, though only performing an ordinary factory duty, were built from entirely new patterns to a design got out in a consulting engineer's office. They are wasteful and extravagant, and probably cost over double what any good firm of engine builders would have charged for far better designs of standard type. Americans are well to the fore in many respects in this matter of standards. Parts of railroad cars are standardised, and we don't know that this fact has done much to prevent progress and change along proper lines of development. We have no such progress-stopping standards on English railroads, yet who will deny that there are vehicles running on the South-Eastern Railway that are of the type of 50 years ago, if not themselves 50 years old? Americans have tried to standardise cement tests. Here every little architect or engineer who calls for the use of a bag of Portland cement must write out a wordy specification for a product of which he has no technical knowledge. Yet every one knows that Portland cement could be standardised under three classes—some men would say one class would cover everything—and might be classed as A, B, or C, and so specified. The question for the consulting engineer himself to determine is how far he is to carry out his own personal supervision. There is a point somewhere between a mere outline of a building and a specification and drawing of the floor brads, at which an architect has to draw the line. It is only a question of degree, and how far we are to go in the direction of designing our own details. In Mr. Fraser's opinion the chief objectors to consulting engineers are the manufacturers of everything; the special manufacturers who make one thing, and that perfect, look on him as a friend. They ought to be able to do so, if only he will do his duty as a selective agent.

Mavor & Coulson's: Machine Shop, West Bay.

In further correspondence on this subject, a Mr. F. J. Johnston implies that consulting engineers have been, at times, poorly informed men. He instances where one electrical engineer in a responsible position sent a flagman to a distance of 1,000 or 1,500 feet with a flag which he was to drop on receiving an electrical signal at a device placed by him. The engineer pressed the button and timed between the pressing of the button and the fall of the flag. The idea of the test was to *determine how long the current required to travel the 1,000 or 1,500 feet!!!*

Mr. Johnston points out that customers select their engineers and place them to overlook contractors, yet customers are no more competent to select engineers than the ordinary layman is competent to select a specialist physician.

Generally, there seems to be an opinion abroad that contractors are very much in the hands of engineers who arrogate to themselves the sole right of judging questions of materials and workmanship, and have the power to hinder work and to throw all kinds of expensive delays in the way of the contractor for which he can make no charge. In fact, the contractor is looked upon as though he were making a huge fortune and is expected to stand all manner of extortion. If engineers will be so extravagant in the demands they make for recognition, they might at least be fair enough to protect the contractor from robbery. Engineers are occasionally far too apt to give ear to any tittle tattle which brings them lying reports of bad work. Such are the views of contractors; to the other side we may next give attention.

CONTRACTS OPEN AND CLOSED.

OPEN.

(*Continued from page* 404.)

Spain.—March 29th. Tenders are being invited by the municipal authorities of the town of Zafra (Badajos province) for the concession for the electric lighting of the public streets during a period of 20 years. Particulars and conditions may be obtained from, and tenders to be sent to, El Secretario del Ayuntamiento de Zafra (Badajoz), Spain.

Switzerland.—April 30th. Plans and estimates are being invited, says the *Contract Recorder*, by the Government authorities of Fribourg, Switzerland, until April 30th next, for a projected electricity generating station to be established at Hauterine. Water-power is to be utilised, and the station will have a capacity of about 6,000 H.P. A premium of £120 will be awarded to the three schemes submitted which are considered to be the best. Plans and estimates are to be sent to the Department des Travaux Publics, Fribourg, Switzerland, from whence full particulars of the competition may be obtained.

The War Office.—April 27th. The Secretary of State for War is prepared to receive offers, competitive designs and specifications for the supply of portable electric search light apparatus. Particulars from the Director of Army Contracts, War Office, Pall Mall, S.W. See our "Official Notices" February 4th.

Victoria.—June 24th. The Council of the city of Hawthorne (Colony of Victoria, Australia) is inviting tenders for the supply and erection of buildings, boilers, engines, dynamos, transformers, mains, meters, arc lamps, poles; also running the plant for three years. See our "Official Notices" March 11th.

CLOSED.

Glasgow.—On 17th inst. the Corporation adopted the recommendations of the Electricity Committee accepting the following offers:—(1) The offer by Messrs. Laing, Wharton & Down, for one engine and dynamo of 700 horse-power at the price of £5,064; (2) the offer by Messrs. Mirrlees, Watson & Yaryan Company, Limited, for one engine and dynamo of 400 horse-power at the price of £1,970; (3) the offer by Messrs. Mavor & Coulson for one engine and dynamo of 900 horse power at the price of £5,775; and (4) the offer by Messrs. Mirrlees, Watson & Yaryan Company, Limited, for one engine and dynamo of 200 horse-power at the price of £1,265. An offer obtained from Messrs. Babcock & Wilcox, Limited, to provide and erect at the new generating station, Port Dundas, two of their patent boilers of about 1,000 horse-power each, with relative superheaters, at the price of £2,020 for both boilers and superheaters was also accepted. Bailie Maclay, in moving the minutes, explained that the engines, dynamos and boilers, contracts for which were thus recommended, represented 2,200 horse-power. They took it that these engineers were bound to deliver the plant by a certain date, somewhere about the end of August. They hoped to have the new works in operation immediately thereafter, and in that way they would be ready to supply current from their two works against the increased demand of next winter. There was urgency in the case, and they were going ahead with the business as quickly as possible. All the engines are Scotch, with the exception of one, which is American.

Salford.—The following is a list of the firms who tendered for the supply of electric cables for the Corporation:—The British Insulated Wire Company (high tension); The Callender Cable and Construction Company, Limited; The Western Electric Company; W. T. Glover & Co. (low tension); W. T. Henley's Telegraph Works Company; Siemens Bros. & Co. The tenders of the British Insulated Wire Company and Messrs. W. T. Glover & Co. were accepted.

West Derby (Lancs.).—For the electric lighting of the Mill Road Infirmary the Board of Guardians have, according to *Daily Tenders and Contracts*, accepted the tenders of the following:—

Boilers.—Messrs. Fawcett, Preston & Co., Liverpool	£1,075
Engine House Plant.—Messrs. Scott, Anderson & Beit, Sheffield	2,085
Batteries.—The Chloride Electrical Storage Syndicate, Manchester	440
Wiring Buildings.—Messrs. W. & J. Robinson, Limited, Bootle	1,411

Mr. T. L. Miller, M.I.E.E., is consulting engineer.

GLASGOW TELEPHONE INQUIRY.

The report of Sheriff Jameson is an example of the disadvantage of government by commission and of the proverbial infelicity of giving reasons for decisions.

The delay in the publication of the report after the taking of the evidence, though considerable, is not so great as to necessitate here a recapitulation of the circumstances under which Sheriff Jameson's inquiry was undertaken. Upon the evidence submitted to him, he finds that the telephone system in Glasgow is not efficient, the inefficiency being mainly due to the refusal by the Corporation of underground facilities to the Telephone Company, but he thinks that the company's service might be improved by a more thorough supervision of the switch room and other improvements; he is more than usually emphatic in expressing his opinion that the comparisons which were introduced with a view to showing that the company's charges were excessive, are altogether outside the circumstances of the case. With regard to the license, he gives reasons for recommending that a license be not given to the Corporation, whilst, in the concluding paragraphs, he suggests that, notwithstanding all the objections he has pointed out, the license should be granted to the Corporation, "throwing on them the whole responsibility of their proposed undertaking," if the Post Office does not itself start a telephone exchange, and provided the Corporation is able to satisfy the Postmaster-General that financially its scheme is sound, and that it has the means of carrying it out.

In forwarding the report the Secretary to the Post Office states that the Postmaster-General is precluded from assenting to the wishes of the Corporation by issuing a license, because in the present state of the law the Corporation has no power to carry on the business of a telephone exchange. Sir J. D. Marwick, the town clerk of Glasgow, in acknowledging Mr. Walpole's letter, takes advantage of the fact that His Grace the Duke of Norfolk "has been so good as to indicate the grounds on which he has arrived at his opinion," and discusses them in some detail, finally concluding with the intimation that if the Post Office will give them a license, they will take the necessary steps to obtain the legal powers.

Thus it will be seen that instead of the question being finally settled upon grounds of public policy, it has been settled in such a way as to invite further argument and agitation. Sheriff Jameson was, doubtless, under the impression that throwing the whole responsibility of their proposed undertaking on the Corporation might act as some deterrent, but the nature of the evidence brought before him should have sufficed to show that the advocates of a municipal service are either insufficiently acquainted with the responsibility, or are willing to undertake any sort of risk with a view to adding a telephone service to their other enterprises. We have on so many occasions pointed out that the decision on telephonic policy must be come to by those who have had proper opportunities for studying the question, and some responsibility in the settlement of it, that we need now only point out how the decision in this case has finally rested with the Post Office. Efforts will undoubtedly be made either to over-ride this decision, or to impugn the motives underlying it. It is certainly to be hoped that neither the Treasury nor Parliament will be coerced or cajoled into removing the decision from the hands of those who have knowledge and a sense of responsibility—the two essential elements needed for a decision on this important question.

Ceylon Technical College.—An Indian paper says that the staff of the Ceylon Technical College has been strengthened by the addition of Mr. Thomas Cockerill, who takes up the post of Instructor of Telegraphy and Electrical Engineering. Mr. Thomas Cockerill, who recently went out to India from this country, is a Fellow of the Chemical Society and an A.I.E.E. He was trained at Owen's College, Manchester, and at the Manchester Technical School. He was lecturer and head of the Electrical Departments at the Bolton Technical Schools and at the Halifax Technical Schools.

NOTES.

Obituary.—It is with great regret that we have to chronicle the death of Col. Dyer, which took place on the 21st inst. at his residence in Manchester. We fear that the arduous and anxious time passed through by him during the recent long strike must have been largely accountable for the accentuation of the organic trouble of the heart which seems to have finally caused his death. As head of the Employers' Federation, he was in the forefront of the battle, and the credit of victory is largely with him, and his sudden death will come as a great blow to the Federation. The incidents and causes of the strike are too fresh for comment to be necessary, but we believe all admit that he was animated by a desire for his country's welfare, and in no way can he be accused of harshness in his dealings with the conquered, whose defeat was, after all, much better for themselves than a victory could have been. Colonel H. C. S. Dyer was a director of Sir W. G. Armstrong, Whitworth and Co., Limited. He joined the Royal Artillery at the age of 18, and saw active service in the Crimea and in India. On retirement as lieutenant-colonel he became assistant superintendent of the Enfield Factory, whence he transferred to Sir Joseph Whitworth, of Manchester, and subsequently to the Elswick Works, which he was instrumental in amalgamating with those of Whitworth, knowing the two places so well. The colonel was of fine and commanding appearance, and in losing him England has lost a representative man of the best type of national character. Born in 1834, he has died at what is now the very early age of 64.

The funeral, which took place on Wednesday at Manchester, was an imposing ceremony, the carriages forming a line more than a mile in length. A large number of the members of the Employers' Federation assembled in the drawing room at Appleby Lodge, Rusholme, the residence of the deceased gentleman. These included Sir Benjamin Browne, Mr. Henderson, Mr. Platt, Mr. Coventry, Mr. Brooks, Mr. Browett, Mr. Alexander Siemens, Mr. Lindley, Col. Peacock, Mr. Sinclair Scott, Mr. Slater Lewis, Mr. Baldwin, Mr. Eddison, and many other gentlemen who took an active part with Col. Dyer in the recent dispute. The utmost sympathy was expressed on all sides, and there was a general feeling that the master engineers had been bereft of a brave and able champion of their cause in the loss of Col. Dyer.

The last issue to hand of Chicago *Electrical Engineering* has a long obituary notice of the late Dr. V. Weitlisbach, who died in November, 1897, in his 43rd year. Dr. Weitlisbach was born in Switzerland, and in the seventies studied under Helmholtz at Berlin. He was manager of the Zurich Telephone Company from 1880 to 1884, and was then appointed chief engineer to the Swiss Telegraph Administration in Berne, under the title of first secretary to the Technical Department. That position he held at the time of his death. Telephone work claimed Dr. Wietlisbach more than anything else, and he has been a frequent contributor to the Berlin and Berne technical press on telephone questions. Dr. Weitlisbach had, at the time of his decease, nearly completed a large and thorough treatise on telephony.

Lectures.—Mr. J. E. L. Barnes lectured at the Birkenhead Town Hall on 16th inst. on "Electric Traction."

Before the Aberdeen Mechanical Society at Gordon's College, on the 18th inst., Mr. Wm. Pickersgill, G.N.S.R. locomotive superintendent, read a paper on "The Economic Use of Electricity for Power Purposes in Railway Workshops."

Mr. Roger W. Wallace, Q.C., chairman of the British Aluminium Company, read a paper before the Society of Chemical Industry on 14th inst. on "Electrical Industries at Foyers."

At the Birmingham Municipal Technical School Engineering Society last week a paper on "The Making and Laying of an Atlantic Cable," was read by Mr. William Smith, the electrical engineer of the Technical School.

At the Royal Scottish Society of Arts meeting on 14th inst. Dr. R adman, F.R.S.E., read a paper on "The Electric Furnace, and Some of Its Uses."

Magnetism and Diamagnetism.—Prof. J. A. Fleming, F.R.S., gave the third of his course of lectures on "Recent Researches in Magnetism and Diamagnetism," at the Royal Institution on Thursday last week, the special subject being the properties of the diamagnetic group of bodies. An experiment was first shown, says the *Times* report, illustrating a method employed by Quincke for measuring the magnetic susceptibility of paramagnetic and diamagnetic liquids. An inverted syphon containing the liquid to be tested, and having one leg much thinner than the other, had its narrow tube placed between the poles of a magnet, when the liquid, if paramagnetic, was drawn up into the field, and if diamagnetic, depressed in the tube. Numerous experiments were then performed with a large electro-magnet, constructed for Tyndall, to show that paramagnetic bodies held in the interpolar field set themselves along the lines of force, whereas diamagnetic ones placed themselves across in the equatorial position. Illustrating Faraday's observation that all substances were affected in one way or the other by a powerful magnetic field, Prof. Fleming caused some amusement by showing that such familiar objects as bread, apple, cold mutton, and tobacco were acted upon by a strong magnet. The influence of the medium surrounding a substance in determining its action in the field was demonstrated by means of other interesting experiments. The peculiar behaviour of crystals called by Faraday magnecrystallic action was then explained, and attention was called to Tyndall's important investigations, during which he discovered that structural changes such as those produced by compressing a substance in any direction greatly affected its magnetic susceptibilities. This fact was demonstrated by means of a piece of bread, which, although diamagnetic, simulated the behaviour of a paramagnetic body after being squeezed, because the line of compression became an axis of greater diamagnetic action. Turning to the action of diamagnetic bodies on light, the lecturer exhibited Faraday's classical experiment, in which a block of magnetised heavy glass (silico-borate of lead) was proved to rotate the plane of a polarised light, and concluded with a reference to the more recent work of Verdet, Kundt and others on magneto-optic effects.

Ward's Omnibus Tests.—There are apparently some errors in the volt readings in the report of these tests, from the 55th minute to the 65th. Amperes 32 and volts 224 may be right; but at the 65th minute, while still 32 amperes, the volts are given 244. Either one or the other must be wrong. At the 95th minute we notice a reading of 40 amperes and 216 volts, and the last reading is 40 amperes and 220 volts. If these figures were correctly noted, it would seem that the battery must have been charging up during the last 10 minutes! The difficulties in reading instruments on board an omnibus may account for a good deal, and the figures can only be taken as a rough approximation, near enough to obtain an idea of the power required. It would be interesting to try how many bus horses would haul that bus home if the battery ran down.

Personal.—We are informed that on February 9th, 1898, Lord Salisbury appointed Mr. Geo. Herbert Bailey Assistant District Commissioner in the Niger Coast Protectorate by telegram. Besides his judicial duties, no doubt when the state of the country under the sphere of influence involved renders it practicable, advantage will be taken of Mr. Bailey's experience of matters telegraphic in connecting up the capital of the Protectorate (Old Calabar) with the African cable system and the establishment of inland telegraphs.

Mr. Lycett is resigning the position of clerk to the Kingswinford Rural District Council, and has become district manager to the British Electric Traction Company.

Mr. R. S. Portheim, of Messrs. D. Bruce Peebles & Co., engineers, of Edinburgh, is sailing for the States on the 26th inst. per ss. *St. Louis*, and will investigate the latest American practice in electric transmission of power.

Will.—The estate of Lord Sackville A. Cecil, whose connection with the telegraph world we referred to in our notice of his lordship's death, is sworn at £249,388.

Municipal Electrical Association.—At a meeting of the Council of the Municipal Electrical Association held at the Westminster Palace Hotel, London, on March 15th, it was resolved to call a general meeting of the Association to be held at the Westminster Palace Hotel, London, on April 19th, at 8 p.m. The following applications for membership were considered and approved. Members:—W. H. Chambers, Gibraltar; C. F. Parkinson, Morcambe; J. K. Brydges, Wakefield; the E. L. Committee, Barrow-in-Furness; the E. L. Committee, Darwen; Stanley Clegg, Darwen. Associates:—S. E. Andrew, Leytonstone; J. C. Vaughan, Leytonstone; T. D. Clothier, Hull; A. N. Puszet, Brighton; N. McLean, Harrogate.

Royal Institution.—The Friday evening lecture arrangements for after Easter include the following:—April 29th, Prof. Andrew Gray, M.A., LL.D., F.R.S., "Magneto-Optic Rotation and its Explanation by a Gyrostatic Medium," (with experimental illustrations). May 6th, Edward A. Minchin, Esq., M.A., Fellow of Merton College, Oxford, "Living Crystals." May 13th, Prof. W. A. Tilden, D.Sc., F.R.S., "Recent Experiments on Certain of the Chemical Elements in Relation to Heat."

Prof. Dewar will deliver the weekly discourse on April 1st. His subject is "Liquid Air as an Analytic Agent."

The Northampton Institute.—Great men are, like the *Daily Mail*, often in advance of the Times, so was last week's *Engineering*. We were under the impression that the Lord Mayor's state visit to the Northampton Institute—to which we refer at length in another column—took place last Friday evening. Our contemporary, however, says the ceremony occurred on the Wednesday previous, so that we and the 2,000 or more who were present on Friday—including the Lord Mayor and Lady Mayoress—arrived just 48 hours behind time!

Technical Education.—The presentation of certificates to art, science and domestic economy scholars, under the Technical Education Board of the London County Council, was made by the Right Hon. Sir Bernhard Samuelson, Bart, F.R.S., at the Northampton Institute, St. John Street Road, E.C., last night.

The Successor of Prof. Galileo Ferraris.—An American exchange says that Prof. Luigi Lombardi has been appointed Professor of Technical Physics at the Industrial Museum of Turin to fill the chair which was left vacant by the death of Prof. Galileo Ferraris.

Mechanical Engineering in Germany.—It is stated by H.M. Ambassador at Berlin that no further applications for admission to the Mechanical Engineering Department of the Technical High School at Charlottenburg, near Berlin, can be received after April 1st next from persons not of German nationality, as the increase of students in that department has been so great that the accommodation is overtaxed.

Damages Awarded.—At the Brompton County Court on Monday, Mr. John Price, an excavator for the new Central London Electric Railway, was awarded, by agreement, £300 and costs, under the Employers' Liability Act. In November last a heavy quantity of earth fell on him, causing motor paralysis of both legs.

Appointment Vacant.—The British Electric Traction Company, Limited, is wanting an electrical engineer to design and construct power houses, and to undertake the electrical equipment of tramways, including rolling stock, but not permanent way. See our "Official Notices" this week.

The Wonders of the Telegraph.—The following marvellous instance of what the electric telegraph is now capable of doing appeared in yesterday's *Standard*:—

HARDING.—On March 19th, at Chefoo, China, the wife of John Reginald Harding, M.I.C.E., of a son. (By telegram).

Private Bills.—The General Power Distributing Company Bill, Central Electric Supply Bill, Chelsea Electricity Supply Bill, and the Metropolitan Electric Supply Bill passed the second reading on Tuesday.

West Ham Wiring Tenders.—Messrs. Allingham and Fennell say that in a published list of tenders for the wiring of the public buildings at West Ham their name is omitted, although a tender was submitted by them for carrying out the work on their "Nomorfyre" system for the sum of £1,139 15s. The town clerk informs them that their tender is being considered with the others.

The Parliamentary Committee.—The House of Commons representatives on the joint committee on electrical energy, generating stations and supply, are Mr. Ashton, Lord Balcarres, Mr. Kimber, and Sir Leonard Lyell.

The Electro-Harmonic Society.—To-night's Concert brings the 1897-98 season of this Society to a close, and it will be pleasant to see a large gathering of members and friends. Classical chamber music is worthily represented by Haydn and Schubert, while piano and violin solos will be represented by compositions of Chopin and Vieuxtemps. Mr. James Gawthrop and Mr. Robert Hilton, whom everybody will be pleased to see again, will sing ballads. The humorous element will be supplied by Mr. W. G. Churcher, and Mr. W. Carlton Smith, and the small string orchestra, which has added so much to the enjoyment of these monthly meetings, will again discourse sweet sounds.

Torquay Municipal Lighting.—The municipal electricity works were formally inaugurated last Friday by the Mayoress of Torquay. In a subsequent issue we shall describe the principal features of the system.

NEW COMPANIES REGISTERED.

London and District Mutoscope Company, Limited (56,367).—Registered March 4th with capital £75,000 in £1 shares, to adopt an agreement with the Mutoscope and Biograph Syndicate, Limited, for the acquisition of a license to use certain patents, to manufacture, sell and deal in mutoscopes, biographs, photographic apparatus, and to carry on the business of electricians, and electrical and mechanical, metallurgical and chemical engineers. The subscribers (with one share each) are:—E. Baker, 29, Cornhill, E.C., secretary; M. J. M. Campbell, Orleans Club, King's Street, W., gentleman; E. J. Nicholas, 29, Cornhill, E.C., secretary; W. Johnson, 8, Shalcombe Street, Chelsea, S.W., clerk; G. Beeson, 2, Clarendon Terrace, W., clerk; S. E. Newman, 72, Romilly Road, Finsbury Park, N., clerk; R. Humphreys, 23, Digby Road, South Hackney, N.E., clerk. The number of directors is not to be less than two nor more than seven. The subscribers are to appoint the first. Qualification, 100 shares; remuneration, £1,000 per annum, and a percentage of the profits divisible. Registered office, 29, Cornhill, E.C.

Phoebus Solder and Electric Soldering Fluid Company, Limited (56,373).—Registered March 4th with capital £4,000 in £1 shares, to acquire and carry on the business of solder, soldering fluid and alloy manufacturers carried on as the "Phoebus Solder and Electric Fluid Company" at 5, York Grove, Peckham, S.E. The subscribers (with one share each) are:—E. E. Bailey, 69, Kilmoirie Road, Forest Hill, S.E., engineer; L. C. J. Graper, 3, Harman Street, Kingsland, N., traveller; J. R. Woodley, Hopton Road, Streatham, S.W., accountant; H. H. Champness, 42, Huddlestone Road, Tufnell Park, N., gentleman; C. G. Cheverton, 43, Breakspears Road, St. Johns, S.E., gentleman; A. H. White, 26, Rosenthal Road, Catford, stockjobber; F. D. Sandell, 12, Ravensbourne Road, Catford, accountant. Table "A" mainly applies. Registered office, 5, York Grove, Queen's Road, Peckham, S.E.

Electric Lighting and Fittings Corporation, Limited (56,379).—Registered March 5th with capital £50 000 in £1 shares to carry on the business of electrical and mechanical engineers, and manufacturers of and dealers in electric, magnetic, telegraphic, telephonic, and other appliances, and steam, hydraulic, pneumatic, and other engines. The subscribers (with one share each) are:—A. Cross, 2, Balliol Road, Bootle, timber merchant; J. A. Dargue, C.E., 175, Bedford Street, Liverpool; J. B. Hepburn, 21, Brasenose Road, Liverpool, engineer; L. Hughes, 23/31, Hatton Garden, Liverpool, merchant; T. H. W. Walker, 41, North John Street, Liverpool, architect; H. Isaac, 23, Great Charlotte Street, Liverpool, fishmonger; C. Birchall, Egremont, Chester, shipowner. The number of directors is not to be less than three nor more than seven; the first are the first five subscribers; qualification, £200; remuneration as fixed by the company. Registered by Cameron, Kemm & Co., Gresham House, E.C.

Best & Lloyd, Limited (56,397).—Registered March 8th with capital £50,000 in £10 shares, to acquire and carry on (1) the business of a manufacturer of, and dealer in, chandeliers and electric and gas fittings carried on by R. H. Best, at Handsworth, Staffordshire, as "Best and Lloyd," and (2) the business of a manufacturer of and dealer in red lead carried on by R. H. Best at Handsworth, Staffordshire, as "J. and H. Lloyd," and to adopt two agreements with the said vendor. The subscribers (with one share each) are:—R. H. Best, Cambray Works, Handsworth, manufacturer; W. R. Nicholl, Northleigh, Olton, near Birmingham, accountant; J. Pinckston, Stowe Villa, Albert Street, Handsworth, manager; G. Vale, Lauriston, Rookery Road, Handsworth, manager; Miss E. H. Best, 23, Radnor Road, Handsworth; Miss L. H. Best, 23, Radnor Road, Handsworth; Mrs. E. M. Best, 146, Hamstead Road, Handsworth. The number of directors is not to be less than three nor more than five; the first are R. H. Best (chairman, with £1,000 per annum); W. R. Nicholl, G. Vale and J. Pinckston; qualification, 50 shares; remuneration, £100 per annum. Registered by Waterlow Bros. & Layton, Limited, Birchin Lane, E.C.

British Electric Meter Company, Limited (56,408).—Registered March 8th with capital £5,000 in £10 shares, to acquire and turn to account a sole selling agency and an option for an exclusive manufacturing license in the Bastian electrolytic meter, and prepayment attachment, and to adopt an agreement with the Tourtel Gas and General Engineering Company, Limited. The subscribers (with one share each) are:—A. V. Askham, 41, Clifford Gardens, Kensal Rise, W., secretary; J. M. Tourtel, 35, St. Luke's Road, Westbourne Park, W., gentleman; C. E. Smith, 1, Wedmore Gardens, Upper Holloway, foreman; J. B. Birnbaum, 2, Long Acre, W.C., merchant; A. Laurmon, 39, Westbourne Street, Sloane Square, S.W., clerk; O. G. Peterson, 82, Weed Vale, Forest Hill, S.E., clerk; W. H. Carlisle, 54, Margravine Gardens, West Kensington, clerk. The number of directors is not to be less than two, nor more than five. The first are: A. F. Davies and J. M. Tourtel. Remuneration, two guineas each per board meeting attended. Registered by Devonshire & Co., 1, Frederick's Place, Old Jewry, E.C.

Costa Rica Electric Light and Traction Company, Limited (56,447).—Registered March 10th with capital £130,000 in £1 shares, to adopt an agreement with M. C. Keith to carry on the business of electric lighting in the Republic of Costa Rica or elsewhere, and to carry on the business of tramway and light railway proprietors, common carriers, electricians, mechanical engineers, &c. The subscribers (with one share each) are:—R. Killman, 14, Sunnyside Road, Ilford, accountant; T. S. Cocks, 71, College Street, Putney, clerk; F. Chipperfield, 179, Choumert Road, Peckham, S.E., clerk; J. C. Holliday, 9, New Broad Street, E.C., clerk; F. H. Firth, Copthall, Twickenham, gentleman; H. W. White, Sydney House, Barrow Road, Streatham, clerk; W. H. Avery, Clareville, Sutton, secretary. The number of directors is not to be less than three nor more than seven; the subscribers are to appoint the first. Qualification, £250; remuneration, £150 each per annum, and £200 for the chairman. Registered by Ashurst & Co., 17, Throgmorton Avenue, E.C.

Premier Electricity Meter Company, Limited (56,448).—Registered March 10th with capital £25,000 in £5 shares, to carry on the business of electric meter manufacturers and dealers, and electricians. The subscribers (with one share each) are:—J. Atherton, 11, Charing Cross Road, W.C., manufacturer; C. M. Downie, 24, Newman Street, Oxford Street, W., electrical engineer; J. Downs, 8, Marlborough Villas, Wimbledon, clerk; W. M. M. Forwood, 15, Union Court, Spl., solicitor; C. O. Grindrod, 11, Knowsley Road, Rock Ferry, Cheshire, gentleman; A. E. Haptie, 5, Durham Road, Seaforth, near Spl., cashier; A. Ruckley, 8, York Road, Seacombe, Cheshire, clerk. The number of directors is not to be less than three nor more than seven. The subscribers are to appoint the first. Qualifications, £100; remuneration as fixed by the company. Registered by T. T. Hull, 22, Chancery Lane, W.C.

Shirras, Laing & Co., Limited (3,793).—Registered at Edinburgh March 10th with capital £30,000 in £1 shares, to acquire the business of Shirras, Laing & Co., ironmongers, blacksmiths, electrical and heating engineers, 46—52, School Hill and Harriet Street, and Back Wynd, Aberdeen, and to carry on and develop the same. The subscribers are:—J. Murray, 28, St. Nicholas Street, Aberdeen, publisher, 300 shares; D. Smith, 27, Argyll Place, Aberdeen, farmer, 400 shares; J. Taggart, 92, Great Western Road, Aberdeen, granite merchant, 200 shares; H. Mortimer, 143, Union Street, Aberdeen, solicitor, 200 shares; G. Shirras, School Hill, Aberdeen, ironmonger, 1,000 shares; R. Haley, School Hill, Aberdeen, ironmonger, 1,000 shares; J. Stephen, 3, Corridean Wynd, Aberdeen, engraver, 250 shares. The directors are to be afterwards appointed. Qualification, 200 shares. Registered by Simpson and Warwick, W.S., 18, Heriot Row, Edinburgh.

Love's Electric Traction Company, Limited (56,471).—Registered March 12th with capital £20,000 in £1 shares to acquire the letters patent for the United Kingdom and various countries other than the U.S.A. and Spain in respect of Love's system of electric traction, to adopt an agreement with J. C. Love and J. E. Hodges, and to carry on the business of electrical and general engineers, machinery manufacturers, tramway and railway proprietors and suppliers of electricity. The subscribers (with one share each) are:—P. W. Goldring, 20, Abchurch Lane, E.C., law student; W. E. Elmslie, 20, Abchurch Lane, E.C., solicitor; H. J. Church, 15, Bendrell Road, Brockley, S.E., clerk; J. Perry, 175, Essex Road, Islington, clerk; J. L. Cooper, 6, Union Road, Tuffnell Park, N., accountant; H. J. Bethell, 128, Beresford Road, Hornsey, N., clerk; A. E. Seamer, 7, Park Place Villas, W., clerk. The number of directors is not to be less than three nor more than seven. The first are:—J. C. Love, J. E. Hodges, W. C. Slaughter, and C. L. Philips; qualification £200; remuneration as fixed by the company. Registered by Goldring & Philips, 20, Abchurch Lane, E.C.

Mid-Air Bulletin Syndicate, Limited (56,507).—Registered March 15th with capital £6,500 in £1 shares, to acquire, own and work certain letters patent granted to S. Crandall, for "improvement in electric signalling and other apparatus," and to adopt a certain agreement. The subscribers (with one share each) are:—F. Brown, Walsall, electrical engineer; J. E. Sheldon, Stafford Street, Birmingham, manufacturer; L. S. Crandall, 62, Moor Street, Birmingham, inventor; W. H. Ryle, 35, Temple Street, Birmingham, land agent; H. A. Pepper, 14, Temple Street, Birmingham, chartered accountant; E. M. Rudland, 14, Temple Street, Birmingham, chartered accountant; J. S. Remington, 97, Castleford Road, Spark Hill, Birmingham, secretary. W. H. Ryle is the first chairman and director. Registered by C. Doubble, 14, Serjeant's Inn, E.C.

Hart Secondary Battery Syndicate, Limited (56,511).—Registered March 15th with capital £5,000 in £1 shares, to adopt an agreement with W. Hart and E. J. Clark, and to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity, and electrical apparatus manufacturers. The subscribers (with 150 shares each) are:—G. W. Kidd, 229, Romford Road, E., licensed victualler; L. W. Spratt, 369, Romford Road, E., draper; J. G. Locks, Lemna Road, Leytonstone, newspaper proprietor; J. G. Abraham, Craiglands, Stroud Green, surveyor; M. Allcock, 97, Clapton Common, N.E., gentleman; G. Hay, 61, Broadway, Stratford, confectioner; S. W. Hart, Oak Dene, South Woodford, surveyor. Registered, without articles of association, by E. Andrew White, 27, Clement's Lane, E.C.

H. M. Salmony & Co., Limited (56,530).—Registered March 16th with capital £25,000 in £1 shares (5,000 5 per cent. cumulative preference), to acquire the business of H. M. Salmony and Co., to adopt an agreement with H. M. Salmony and E. Rosenberg, and to carry on the business of electrical and mechanical engineers, manufacturers of, and dealers in, electrical apparatus, and contractors for the supply of electricity. The subscribers (with one share each) are:—G. S. Hein, 71, Lombard Street, E.C., bank manager; F. Salmony, 166, Finchley Road, N.W., stock jobber; T. J. Digby, 30, Princess Road, South Norwood, electrical engineer; F. H. Minn, 77, Grange Park Road, Leyton, E., electrical engineer; J. Hart, 69, Linden Gardens, W., electrical engineer; H. M. Salmony, 26, Winchester Road, Swiss Cottage, N.W., electrical engineer; E. Rosenberg, 34, Dryden Chambers, Oxford Street, W., electrical engineer. The number of directors is not to be less than four nor more than six; the first are H. M. Salmony, E. Rosenberg, and H. Schwabe. Qualification, £250 debentures, or £100 shares; remuneration as fixed by the company. Registered by M. Abrahams, Sons and Co., 80, Old Jewry, E.C.

Direct Telephone Exchange Syndicate, Limited (56,542).—Registered March 17th with capital £5,000 in £1 shares, to adopt an agreement with H. Leupold & Vautin, and to carry on the business of a telephone, telegraph, electric light, heat and power supply company. The subscribers (with one share each) are:—P. H. Gardner, 47, Burnam Road, Tollington Park, N., accountant; J. E. T. Wells, 13, Knoyle Street, New Cross, S.E., clerk; J. T. Hayter, 8, Mehetabel Road, Hackney, N.E., writer; C. H. Weeks, 60, Foxham Road, Tufnall Park, N., solicitor; C. Hof, 52, Leadenhall Street, E.C., merchant; B. Steinert, 218, Winchester House, E.C., gentleman; H. Leupold, 20, Grange Road, Norwood, S.E., gentleman. Table "A," mainly applies. Registered by A. Maxwell, 41, Bishopsgate Street, E.C.

The National Engineering Supply Company, Limited (3,808).—Registered at Edinburgh March 18th with capital £2,000 in £1 shares, to carry on the business of steam and electrical engineers, machinery and metal merchants, and agents. The subscribers (with one share each) are:—T. McStraith, 70, Wellington Street, Glasgow, accountant; M. Brown, 5, Hayfield Terrace, Glasgow, merchant; W. Thorn, 14, Scott Street, Bridgeton, Glasgow, clerk; J. Smith, 70, Wellington Street, Glasgow, engineer; A. Paterson, 109, Bath Street, Glasgow, writer; G. Chapman, 109, Bath Street, Glasgow, writer; J. McTaggart, 78, Kelvin Street, Glasgow, builder. Directors are to be afterwards appointed; qualification, 100 shares. Registered by Breeze, Paterson & Chapman, 109, Bath Street, Glasgow. Registered office, 312, Argyle Street, Glasgow.

OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

Headland's Patent Electric Storage Battery Company, Limited (45,524).—This company's annual return was filed on January 18th, when 19,665 shares were taken up out of a capital of £20,000 in £1 shares. 14,993 are considered as paid, £1 per share has been called on seven, and 10s. per share on the remainder. £2,389 10s. has been received, which includes £50 paid in advance.

Harp Arc Lamp Syndicate, Limited (41,057).—As this company is not doing any business, the secretary has requested that its name be erased from the Register of Joint Stock Companies.

Buenos Ayres Electric Light Company, Limited (16,057).—This company's annual return was filed on January 1st. The capital is £100,000 in 9,986 shares of £10 each, and 70 founders' shares of £2 each. All the latter have been subscribed for, but no calls have been made.

CITY NOTES.

Hanley Corporation Accounts.

NOTWITHSTANDING the short period for which the loans in the case of Hanley have been granted, the electricity works are rapidly arriving at a profit-earning stage, after paying contributions to sinking fund and interest on loans. The following paragraphs from the engineer's report are worth quoting:—

"The total expenditure was £4,000 7s. 8d., and the total receipts were £6,520 1s. 7d., according to the Board of Trade returns, leaving £2,519 13s. 11d. as the gross profits of the undertaking to be carried to the net revenue account. This amount represents a profit of 4·88 per cent. on the capital expended. The receipts do not show such an increased consumption as was hoped for by the reduction in price from 6d. to 5d.; in fact, the customers who formerly paid 6d., taken collectively, and of course including corporation buildings, have consumed less current in 1897 than in 1896. This seems conclusively to point out that a much greater inducement was necessary to bring in long-hour consumers, and this has now been given; but owing to hesitation on the part of intending customers, the good results may not come immediately. The lowering of the price, particularly to private houses and to shops having long hours should, however, during the ensuing few years, prove to be a wise and sound course, unless Hanley is to be different from all other places.

"It will be noted that notwithstanding the reduction in price, the very great addition to the sum required to be paid to the sinking fund and the large sums expended in maintenance, rates and taxes, that the deficiency is so small an amount as £188 11s. 1d. on a gross income of £6,520. A very few additional customers would have converted that amount into a net profit, in fact, the new connections made already more than warrant the belief that such a sum will be cleared off in the first half-year. The effect of the new optional charges is, of course, a distinct matter. If the price had remained at 6d. and the same quantity sold, the income would have been £1,000 more. On the other hand, the lowering of the price has undoubtedly brought new customers in, and it is only reasonable to estimate that the loss caused by the new charges during the first half of this year will be balanced by the gain in the second half."

The following table shows the increase in the various items:—

INCREASE.

Capital expenditure.	Output in units.	Working expenses.	Revenue from sale of current.
£7,491	3,881	£1,400	£1,930

The following table gives the cost per unit:—

	1897.	1896.
Total capital expended	£51,684	£44,143
Number of units sold	351,762	247,881
Number of lamps connected	—	—
Revenue from sale of current	£6,292	£4,362
Net revenue	£2,520	£1,791
Average price obtained per unit	4·2d.	4·5d.

Cost of production.	£		Per unit.	1896.
Coal	1,003		·68d.	·73d.
Oil, waste, water, and engine room stores	226		·15d.	·19d.
Salaries and wages at generating station	887*	Works' cost 2·07d.	·60d.	·57d.
Repairs and maintenance of buildings, engines, boilers, dynamos, &c.	992*		·67d.	·50d.
Rent, rates and taxes	357		·24d.	·15d.
Management expenses, directors' remuneration, salaries of managing engineer, secretary, clerks, &c., stationery and printing, general establishment charges, auditors, law charges, and insurance	535		·36d.	·38d.
Depreciation of buildings and plant account	—		—	—
Renewal fund account	—		—	—
Total	£4,000		2·70d.	2·52d.

Revenue.	£	s.	d.	Average price obtained per unit.
By sale of current	6,292	0	0	4·2d.
Meter rents, &c.	150	0	0	—
Supply of steam	—			—
Transfer fees	—			—
Other items	78	0	0	—
Total	£6,520	0	0	4·2d.

* Attending and repairs of arc lamps (£295) added to these two items.

Total cost per unit (exclusive of depreciation and renewal accounts), 2·67d.; works' cost, 2·07d.

The Hove Electric Lighting Company.

THIS company continues to make substantial progress, and though it has, during the past year, made a considerable reduction in the price charged for electricity, there is every reason to anticipate an increased *clientèle* from that cause alone. There is a marked decrease in the cost of production, the most striking being in the repairs and maintenance account, which stands at £209, against £340 last year. Considerable extensions to the company's systems have taken place, and probably the next accounts will demonstrate the benefits arising from enlarging the scope of the company's operations.

The increase in the various directions are indicated below:—

INCREASE.

Capital expenditure.	Output in units.	Working expenses.	Revenue from sale of current.
£4,874	67,681	£262	£677

The following table gives the cost per unit:—

	1897.	1896.
Total capital expended	£66,896	£62,022
Number of units sold	268,243	200,562
Number of lamps connected	27,777	21,794
Revenue from sale of current	£6,839	£6,162
Net revenue	£3,602	£3,114
Average price obtained per unit ...	6·11d.	7·39d.

Cost of Production.	£		Per unit.	1896.
Coal	805		·72d.	·79d.
Oil, waste, water, and engine room stores	119		·11d.	·16d.
Salaries and wages at generating station	785		·70d.	·88d.
Repairs and maintenance of buildings, engines, boilers, dynamos, &c.	209	Works' cost 1·72d.	·19d.	·41d.
Rent, rates and taxes	184		·16d.	·27d.
Management expenses, directors' remuneration, salaries of managing engineer, secretary, clerks, &c., stationery and printing, general establishment charges, auditors, law charges and insurance	1,172		1·04d.	1·28d.
Depreciation of buildings and plant account	—		—	—
Renewal fund account	—		—	—
Total	£3,274		2·92d.	3·79d.

Revenue.	£	s.	d.	Average price obtained per unit.
By sale of current	6,839	0	0	6·11d.
Meter rents, &c.	—			—
Supply of steam	426	0	0	—
Transfer fees	4	0	0	—
Total	£7,269	0	0	6·11d.

Total cost per unit (exclusive of depreciation and renewal accounts), 2·92d.; works' cost, 1·72d.

The Electric Installation Company, Limited.

THIS company has been formed for the purpose of making installations of electric plant for lighting or other purposes in public institutions, hotels, mills, factories, collieries, warehouses, shops, &c., on the hire-purchase system or on a rental. It is not proposed that the company should manufacture the different appliances required in such installations, but that its revenue should be derived from payments to be made for the hire and rental of electric plant. Generally, arrangements with customers would be such that all claims against them would be satisfied after the rental had been paid for 10 years. It is obvious that such a scheme calls for heavy expenditure, and it is not surprising, therefore, to find that the capital of the company which is courageous enough to embark upon such an enterprise is £100,000 in £1 shares. The immediate call is for 2s. 6d. on application and 2s. 6d. on allotment. In a sense, the company may be considered a Manchester one. The directors are mainly Manchester merchants, the offices of the company are in Manchester, and the consulting engineer is Mr. F. F. Bennett, of Manchester. No doubt Lancashire and the north country generally presents a very favourable field for the operations of the company, and we see little reason why it should not meet with some success. It is exceptional, not to say remarkable, that in this company no promotion money will be paid; there are few electrical companies that can say the same.

Brockie-Pell Arc Lamp Company. The report of this company, covering a period of 17 months, has just been issued, but it is impossible in this issue to do more than make a few extracts from it. Profit and loss account show on the debtor side, £7,737, the principal items of which are, directors' fees, £1,676; and salaries, £3,257. The credit side shows manufacturing gross profit, £2,085, and royalties nearly £1,000, there being practically a loss of £4,590 on the 17 months' working. According to the report, this is mainly due to the time taken in equipping the works with the various machines for the making of the lamps. The first 100 lamps, made entirely at the company's factory in Tabernacle Street, were not completed till the end of July last, so that the business has only been in full swing for a period of from five to six months. Orders for lamps received from month to month, show a steady increase. A contract has been signed for the disposal of the French and Belgian patents for £3,000, of which £500 has been received on account.

Chelsea Electricity Supply Company, Limited.

Mr. J. Irving Courtenay presided at the general meeting of this company held last Thursday, and said it was a pleasure to him to be able again to report a continual improvement in the results obtained. The £60,000 ordinary share capital subscribed in 1896 did not rank with the ordinary capital previously subscribed until 1897, and, notwithstanding this additional capital, the increase in the business had enabled them to show a profit which would allow of 6 per cent. being paid on the ordinary shares, as compared with 5 per cent. on the smaller capital of previous years, carrying forward a balance of £1,652 4s. 1d. to meet contingencies. That the public was now fully alive to the value of the electric light was amply demonstrated by the substantial addition to their circuits of over 16,000 lamps during the year, and the large increase in the use of the light generally throughout the metropolis and in the provinces. That fact was of itself an explanation of the necessity for the expansion in capital expenditure, and so long as this expenditure brought an increasing return, none would have cause to complain. They had added a valuable security to the property in the form of freehold land, and substantial buildings on this land, to the extent of over £20,000, and had increased the plant, machinery, mains and meters by nearly £35,000. The progress during the year had been continuous and steady, and it really seemed as if an average of 16,000 or 18,000 lamps annually would continue to be added. They must, however, make provision for somewhat larger additions, because it frequently happened that a new estate would be completed, and shops and offices all opened at once; constant care was exercised by the staff in watching the progress of the various estates. The new sub-station in Pavilion Road was of sufficient capacity to cope with the maximum demand ever likely to arise in its neighbourhood. They had laid, during the year, about 9¼ miles of casing, which was capable of accommodating about 36 miles of conductor, and had actually drawn in during the year some 16½ miles of conductor into the ways just mentioned. There were added during the year 16,178 lamps, or their equivalent in the 12 months, so that the total number of lamps on December 31st was 96,758, since which they had passed the hundred thousand. The chairman then referred to the compulsory purchase of property adjoining, and in the neighbourhood of, their works in Chelsea, for which a Bill had been promoted in Parliament. The cost of production had been slightly reduced, and, from the character of their district, the improvements introduced in their machinery, and the indications in the present accounts, they might fairly expect progressive improvement in the return on capital. In regard to vibration troubles, their works were now equipped with the most recent type of plant, and every precaution that the best practical experience could suggest had been taken, and as they had, in addition, made a careful inspection of the property in the neighbourhood, they had no fear of the ultimate issue of any complaints that may be made against the company.

The report and accounts were then adopted.

South London Electric Supply Corporation.

The ordinary general meeting of the South London Electric Supply Corporation, Limited, was held on Monday last at Winchester House, E.C., Mr. George Ellis, J.P., presiding.

The Chairman said: Steady progress was being made in all directions. Most new undertakings suffered from delays; theirs, so far, had not been very serious, and had been amply compensated for by the acquisition of the site which they had succeeded in obtaining after lengthy negotiations. It was practically in the centre of the area of supply; it required no clearing and hardly any levelling, and the three acres of freehold land cost under £10,000; a better site for the operations there could not be. Referring to the accounts, a certain proportion of the administration expenses had been allocated to the cost of land, buildings, machinery, plant and mains. It had been stated that no dividend could be paid till the cost of the order and expenses, amounting to £47,000, had been paid off. This was not true; the expenditure could be placed to a suspense account. The Board of Trade would allow a dividend to be paid so long as a suitable amount was set aside for the extinction of the item. No doubt some of them had been told that £47,000 was a large sum for this order and the expenses. On the face of it, it does seem large, but it is not so in fact. The Board of Trade insisted upon the capital being underwritten to the extent of £200,000 before they would let this company have the order, and that in itself, with the brokerage, absorbed £24,000 of the amount. He should like to compare the expenditure with that of two other large companies in London—namely, the Westminster and the St. James's Companies—and to say that their order had not cost them one-half of what theirs had cost them, because in one case they had had to redeem their founders' shares at a cost of £120 000, and in the other case he believed at £150,000, whereas £47,000 was the absolute cost to them of this order. With regard to the issue of the balance of the share capital, the facts of the case are these: the shares subscribed for gave them a little over £200,000 to fulfil contracts and carry out works involving an expenditure of about £300,000. In July last they could not get more capital, as the shares were considerably below par, and it was illegal to issue shares at a discount. Any offer to the shareholders which it had been suggested should have been made, would still further have depreciated the shares and have thus added to the difficulties. The board had many serious consultations, and at last most reluctantly instructed their engineer to cut down the contracts; but then arose an unforeseen difficulty. They were under an obligation to the Lambeth Vestry to build a dust destructor capable of burning a certain number of tons of refuse per annum, so that this, the largest contract, could not be reduced. They, however, arranged to cut down the engines, cables, and other machinery by one-third, but they did this only as a last resource, as they knew full well that this meant doing away with any possibility of early dividends; but there was, at that time, no other course open to them. However, on July 29th, Mr. Cook, a gentleman whom the board knew to be connected with a strong group of financiers, called on the board and offered to take the 1,530 shares necessary to obtain a Stock Exchange quotation, at par—although shares could be purchased in the open market at a considerable discount—conditionally upon giving him an option at par for the balance up to December 1st. Mr. Cook told them in the most straightforward manner that he was representing some financial gentlemen of considerable means, and the inference they drew from this statement was that it was almost certain the option would be exercised, and that the necessary funds for carrying out the scheme in full were sure to be provided. Mr. Cook, however, found some difficulty at the outset in making his arrangements, as so many people had left London for the holidays, and at the next board meeting he asked for a month's grace. This was agreed to, and at the end of that time the cheque was forthcoming, and application for a Stock Exchange quotation was duly made and granted. Subsequently Mr. Cook transferred his option to Mr. Atherton, the gentleman who had some months previously promoted the company, and he at the expiration of the option at the end of November, came to the board and offered to take up and pay for the whole of the shares covered by it if the board so desired. He, however, made another proposal, to the effect that he should then only take up and pay for 12,500 shares out of the 21,659, leaving the balance—namely, 9,159—over until March 1st, and paying to the company interest at the rate of 4 per cent. on the £18,318. The board thereupon considered which of these two offers would be most beneficial to the company, and came to the conclusion that Mr. Atherton's second proposal was the better. They had read Mr. Wheelock's circulars, and he (the chairman) had told them the facts. As directors, they had only to consider the true interests of the company. With no quotation, with shares at a discount, and insufficient capital at their command to carry out their programme, the directors were satisfied that in placing the balance of capital as they did, they acted as men of business in the interests of the shareholders. None of the directors had any interest in the allotment made to Mr. Atherton, either directly or indirectly. In order to show that they had not allowed the work to lag, he might mention that the local authorities had represented that the progress in laying the mains was somewhat too rapid to enable them to keep pace with the company in the work of reinstating the streets, a compliment which was most satisfactory. The chairman then moved the adoption of the report.

Mr. Brooke-Hitchin seconded the motion.

Mr. A. Brooke moved the following amendment: "That the report be received but not adopted, and that a committee of five shareholders be appointed, with power to add to their number, to inquire into the formation and past management of the company, and the relations between the board and the promoter, and with power to call for books and documents, and to obtain such legal and professional assistance as may be necessary, such committee to report to a meeting to be called for Monday, April 18th, 1898."

After some discussion the amendment was negatived, only four votes being recorded in its favour, and the report and accounts were adopted.

The Direct Spanish Telegraph Company, Limited.

The report and accounts of the directors for the year ended December 31st, 1897, to be presented at the yearly general meeting of shareholders, to be held on Tuesday, March 29th, 1898, states that the accounts for the year ended December 31st, 1897, show, after providing for interest on, and redemption of, debentures, a balance to the credit of revenue of £12,975 6s. 4d. After adding the usual sum of £5,000 to the reserve fund, the balance will amount to £7,975 6s. 4d., and the directors recommend the declaration of dividends for the year 1897, of 10 per cent. on the preference shares, and 4 per cent., free of income-tax, on the ordinary shares, absorbing £5,486 4s. Half of this amount was distributed on October 1st, 1897, as an interim dividend in respect of the half-year ended June 30th, 1897.

The traffic receipts show a decrease of £2,927 3s. 11d., as compared with the year 1896, when, as stated in last year's report, the increase was due to exceptional circumstances. The reductions of rates, and the mode of counting the words in telegrams, adopted at the Buda-Pesth Conference, came into force on July 1st, 1897, and have, as was expected, adversely affected the company's receipts.

The working expenses are £223 8s. 11d. in excess of those for the year 1896. The company's cables and land lines in connection with them have continued in good working order throughout the year. In the report of the directors of September 11th, 1894, it was stated that the construction of a new breakwater at Bilbao placed the company under the necessity of removing the shore end of the Falmouth-Bilbao cable to a point outside the new breakwater, and that the cost of this removal was chargeable to the harbour authorities at Bilbao.

The directors regret that the liability of the harbour authorities was not admitted by the Spanish Courts. The cost of the removal of the shore end, amounting to £3,514 5s. 2d., has, therefore, been debited to the reserve fund, and it is proposed that the balance of the revenue account, amounting to £2,489 2s. 4d., be transferred to the reserve fund towards the payment of this amount, and that the £1,025 2s. 10d., required to make up the cost of the removal, be repaid to the reserve fund out of future revenue. The reserve fund now amounts to £44,769 11s. 2d. The directors report, with extreme regret, the death of Mr. Edmund Etlinger, who had been a director of the company since its formation in 1872. The directors have filled the vacancy so caused by the appointment of Mr. F. Alexander Johnston.

In commemoration of Her Majesty's Diamond Jubilee, the directors have granted a bonus to all employés in the company's service.

Mr. F. Alexander Johnston is the director retiring by rotation, and offers himself for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths & Co., retire, and offer themselves for re-election.

Willans & Robinson, Limited.

The eighth half-yearly report of the directors, to be submitted at the ordinary general meeting of the company, to be held at the City Terminus Hotel, Cannon Street, London, at 3 p.m., on Wednesday, March 30th, 1898, states that the accounts for the half-year ended December 29th, 1897, are submitted herewith. After writing off as depreciation from plant, patents, &c., the sum of £5,277. 8s. 4d. (against £4,162 11s. 2d. last half-year), and paying interest upon debenture stock, the balance to the credit of profit and loss account for the half-year (including £1,859 13s. 7d. brought forward) is £16,053 0s. 10d. Out of this the directors propose that dividends be paid at the full rate of 6 per cent. per annum upon the preference shares, and at 8 per cent. per annum upon the ordinary shares, together amounting to £8,707 17s. 7d. The amount payable to the original directors, in accordance with the articles of association, is £1,832 5s., leaving a balance of £5,512 18s. 3d. From this the directors propose to carry £2,000 to the debenture redemption fund, and £1,500 to the reserve fund (against £1,000 last half-year), leaving a balance of £2,012 18s. 3d. to be carried forward. The directors feel that the satisfactory results of the half-year's trading, achieved under circumstances not altogether favourable, coupled with excellent prospects for the future, justify them in recommending a moderate increase of dividend.

In accordance with the announcements made in the last report, applications have been invited from the shareholders for the balance of the unissued shares, viz., 3,000 preference and 3,000 ordinary shares.

As required by the articles of association, two of the directors, viz., Mr. Robinson and Capt. Sankey, retire, but are eligible, and offer themselves for re-election.

The auditors, Messrs. Cooper Bros. & Co., also retire, but are eligible for re-election.

Hastings Electric Light Company.

The annual meeting was held last week at the Queen's Hotel. Mr. F. A. Langham presided.

The Chairman, in moving the adoption of the report and balance-sheet, said they had to work for three years under a losing contract. It was difficult to say how much they lost, but certainly several hundreds a year, through being originally misinformed as to the cost of producing the light. They had had to feel their way, and unfortunately they had to pay for it. Now that was at an end it was evident they had a good and prosperous concern, and he thought nothing showed it more than the figures which they had alluded to in their report, comparing the receipts for the light supplied as against the cost of production. For his own part, and on the part of the directors, he must say they were deeply indebted to Mr. Andrews and to those who were working under him for the pains they had taken to obtain the result of economy which was shown in that report. He thought it did great credit to their staff that with increased receipts and increased working, although they had been able to earn about £1,600 more, it should have been done at an additional cost of under £200. Their receipts had been steadily increasing for the past three years. In 1895 they were £6,090; in 1896 they had increased to £7,086, and in 1897 they rose to £8,734; therefore, it was a regularly increasing business. They were taking more money each year, and they had fair grounds for supposing, with contracts in hand, and the orders given to them, that that state of things would extend to the present year also. Their working expenses in 1896 to earn £7,086, were £5,164, whereas in earning £8,734 in 1897, their expenses were only £5,361, so that in earning £1,600 or £1,700 more, they expended something under £200 more in the working. It was very agreeable to them to find that the popularity of the light was increasing, and that they got new customers, because, of course, as soon as they ceased to supply the town—which they were still doing, although on more remunerative terms—they would have spare light for private customers. As they knew, since their last annual meeting, they had had a special general meeting, at which the shareholders unanimously adopted the suggestions of the board, that the contract with the Corporation should be entered into. That contract was accordingly entered into; but at present nothing further had been done, because the Corporation were seeking to obtain their provisional order, without which they could not take the works over. They, at present, were still lighting the front line under arrangement with the Corporation from month to month, until the Town Council were able to supply light for themselves. But they did not anticipate, even when they lost this lighting, that they would sustain any loss, because they had considerable demands for private lighting, which they could carry out, but which they had been afraid to add to the burden on the machinery already taxed with the public lighting.

Mr. A. Bray seconded the motion, which was adopted.

The Metropolitan Electric Supply Company, Limited.

The report of directors to be presented at the ordinary general meeting next Tuesday at Winchester House, states that the directors submit a statement of the company's accounts for the year ending December 31st, 1897, prepared in the form prescribed by the Board of Trade under the provisions of the Electric Lighting Acts, 1882 and 1888.

The capital expenditure, which at the end of 1896 amounted to £757,035 13s. 11d., has now reached a total of £850,831 10s. 9d., the increase during the year having been £93,795 16s. 10d. The principal items are mains and apparatus, and the purchase of a site for future extensions. The balance of capital in hand at the end of the year was £29,597 18s. 10d. The gross revenue for the year amounted to £138,267 14s. 6d. against £116,459 4s. in 1896, being an increase of £21,808 10s. 6d. The cost of generation, which in 1896 was £52,619 4s. 9d. amounted in 1897 to £58,604 5s. 4d., or an increase of £5,985 0s. 7d.

The balance to the credit of the revenue account, before providing for depreciation, is £58,721 10s. The directors have set aside £15,000 as an addition to the depreciation account carrying to the credit of the net revenue account, the sum of £43,721 10s. which, with the balance brought forward from last account and other receipts, makes a total of £46,917 3s. 6d. After deducting debenture and share interest and other charges, there appears a balance of £22,989 6s. 6d. An interim dividend of 5s. per share on the ordinary share capital was paid on October 15th, 1897, amounting to £12,475, and the directors recommend that a further dividend of 7s. per share on such shares be now paid, making a total distribution of 12s. per share for the year, or 6 per cent. on the capital. The dividend upon the new shares being for six months only, will be 6s. per share, or one-half the total amount of dividend upon the original shares. This will absorb a further sum of £21,215, and leave a balance of £1,774 6s. 6d. to be carried forward to the next account.

The number of 8-candle-power lamps supplied by the company increased during the year 1897 from 308,000 to 360,000. The present number of lamps connected is 374,000, and the applications show no signs of decrease. A report from the company's engineering director is appended, showing that the satisfactory condition of the stations, machinery, and plant has been maintained.

In accordance with the articles of association, the following directors, viz :—Admiral of the Fleet Lord John Hay, G.C.B., W. Harrison Cripps, Esq., and John Birkbeck Lubbock, Esq., retire from the board, and are eligible for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths & Co., also retire, and are eligible for re-election.

Sheffield Electric Light Company.

The annual meeting of the company was held on Monday last at the Cutler's Hall, Sheffield.

The Chairman of the Board (the Lord Mayor, Alderman Franklin) presided at the ordinary meeting, and in moving the adoption of the report, congratulated the shareholders upon the sound financial position of the company, and in several ways pointed to unmistakeable proofs of progress. In 1893 the revenue from the sale of current was £3,555, and it increased year by year until in 1897 it reached £14,318. The profits had increased in the same way, and for the past year amounted to £11,392, out of which it was proposed to pay a dividend of 12½ per cent., and carry forward £902. The output was 747,067 units, against 483,427 units in 1896 and 288,406 in 1895. The greatest percentage of increased output was in 1896, when the increase was 67 per cent., against 54 per cent. last year, but the reason of that was that owing to the impossibility of getting additional machinery, chiefly in consequence of the engineering dispute, the company declined to receive new customers for several months. He alluded to, and laid stress upon, the decreased cost of production, stating that in 1893 the cost of production was 5·44d. per unit, in 1894 3·8d., in 1895 3·6d., in 1896 2·23d., and in 1897 1·56d. Within a period of 15 months the directors had brought down the cost of production from 2½d. per unit to about 1½d. The directors were convinced they had a valuable property, and they were well satisfied with the progress which had been made.

Alderman Gamble seconded, and the report was adopted, as was also one declaring a dividend of 12½ per cent.

A special meeting followed, to approve the sale of the undertaking to the Corporation of Sheffield.

The Chairman moved the formal resolution, agreeing to sell to the Corporation, and the resolution was unanimously carried.

Manchester Electrical Works, Limited.

The following report and balance-sheet have been sent out to the shareholders of the Manchester Electrical Works, Limited (successors to Woodhouse & Rawson): —

"147, Leadenhall Street, E.C., *March 9th*, 1898.

"Sir or Madam,—Your directors have not considered it necessary to call a general meeting of shareholders during the past year, because they prefer to have some definite proposals to place before you regarding the disposal of the works, which they have been endeavouring to bring about on behalf of the shareholders. Negotiations for the sale are still pending, and as soon as a firm offer can be secured at a sufficient price, a meeting of the shareholders will at once be called to confirm the sale. In the meantime the money that you have subscribed is secured by a charge on the plant and stock, and carries with it 5 per cent. interest until such time as it is repaid. Your directors beg to forward balance-sheet, showing the financial position on December 31st, 1897. You will notice that the total expenditure for salaries and office expenses since the incorporation of the company amounts to £153 2s. 6d. There has been, and will be, no further addition to this item, and your directors will continue, as in the past, to waive their fees.

"Yours faithfully,

"Willoughby Wallace, *Chairman*."

The British Insulated Wire Company, Limited.

The first ordinary general meeting of this company was held last week at the Exchange Station Hotel, Liverpool, Mr. W. Marriner Brigg, chairman of the board of directors presided. There were also present Mr. E. K. Muspratt, Mr. S. Z. de Ferranti, Mr. J. B. Atherton, and Mr. J. E. Pearson, directors; Mr. F. J. Leslie, solicitor; Mr. Edward Tracey, secretary, and a considerable number of shareholders.

The report, which was for the first eight months of the company's working, ending December 31st last, stated that the net profits for that period were £33,281, which the directors regarded as very satisfactory, being in excess of the estimate in the prospectus. They recommended a dividend at the rate of 15 per cent. on the ordinary shares.

The Chairman, in moving the adoption of the report and accounts, expressed the pleasure of the directors at meeting the shareholders under such happy circumstances. They had already found it necessary to enlarge their working premises, and further buildings were in progress, in order to enable them to keep pace with the orders in hand. Fortunately their area of land at Prescot was large enough for the extensions required, and already a competent authority had informed him that they had the most complete and best laid out works in the country. When the new company took over the business they had £200,000 worth of orders on hand. The figure now stood at £300,000, and personally, he felt confident that ere long they would require a further issue of capital in order to keep pace with the demands upon them. He was satisfied that they could employ a very much larger capital profitably. He, therefore, felt entitled to congratulate the shareholders, both as to what they had already done and on the excellent prospects before them.

Mr. Berry seconded the motion, which, after a brief discussion, was unanimously adopted, and a dividend was declared as recommended.

On the motion of Mr. Muspratt, the retiring directors, Messrs. W. M. Brigg and Ferranti, were unanimously re-elected, and Messrs. Chalmers, Wade & Co. were re-appointed auditors.

A hearty vote of thanks to the chairman and directors concluded the proceedings.

Norwich Electricity Company.

The ordinary general meeting of the shareholders was held last week. The chairman, Mr. F. W. Harmer, presided.

The Chairman said he trusted that the report which they held in their hands would be looked upon as satisfactory. The most interesting item of the report was the balance, either to the debit or credit of the account, and the amount which was allotted for the purpose of dividend. They had never had a debit balance yet, and he hoped that they never would have. At the end of the first year's working they had declared a modest dividend of 3 per cent., and they had been able to make it a little better each year. 1897, he was glad to say, was the best they had had. He hoped the shareholders would think that the 5½ per cent. now declared was very fair for a young company like their own, and it was especially gratifying because, as they knew, 12 months ago the price of current had been reduced 12½ per cent. Owing, however, to economy in working, and to the fact that they had acquired a large number of new customers the result of the year's working was even more than that of 1896. The directors were increasingly satisfied that they had adopted the right system of producing electricity, and that was a very important matter. As to economy of working they might compare with the best companies in England. The price at which they were making electricity was considerably below the average of the whole country, even including those of the Midland counties where coal was much cheaper than it was in Norwich. The capital account had been kept down to the lowest possible figure, and, compared with the revenue they obtained for it, was below the average. The most interesting feature which he had to report was that they did not seem to be getting to the end of their prosperity. They were acquiring new customers at this moment as fast as they were last year at this time, or, indeed, at any period in their history. They had lately adopted a system of free wiring, which would probably bring them a considerable amount of new business, which they could not have obtained in any other way. The directors had not only put aside this year a certain amount for depreciation, but also another sum as reserve. Machinery was constantly wearing out, and it was not so valuable at the end of a year's working as at the beginning. The company had been applied to to supply electricity in Thorpe, and they were now applying to Parliament for an Act to enable them to do so.

The report, after some discussion, was adopted.

Brush Electrical Engineering Company.—The interim report of the directors of the Brush Electrical Engineering Company for the six months ending December 31st last states that the works at Loughborough have been fully employed, and the volume of orders received during the half-year has been above the average of the past few years. In consequence of the increasing demand for the company's manufactures in connection with electric traction, the directors are largely extending the capacity of the works for the output of motors and cars. Other extensions of the works at Loughborough, rendered necessary by the development of the company's general business, are in progress. A final settlement of the matters in dispute with the City of London Electric Lighting Company has been effected. An interim dividend for the half-year at the rate of 6 per cent. per annum has been declared on the company's preference shares.

Stock Exchange Notices.—Application has been made to the Committee to appoint a special settling day in, and to grant a quotation to, Westminster Electric Supply Corporation, Limited—£200,000 3½ per cent. first mortgage debentures.

The Committee has appointed Tuesday, March 29th, a special settling day in W. T. Henley's Telegraph Works Company, Limited —Further issue of 2,500 ordinary shares of £10 each, fully paid, Nos. 10,001 to 12,500; and ordered the undermentioned to be quoted in the Official List:—St. James's and Pall Mall Electric Light Company, Limited—Further issue of 12,000 ordinary shares, Nos. 40,081 to 52,080; W. T. Henley's Telegraph Works Company, Limited—Further issue of 2,500 ordinary shares, Nos. 10,001 to 12,500.

Costa Rica Electric Light and Traction Company, Limited.—The share capital of this company, which has been formed to supply electric light and operate electric tramways in San José and Cartago and to take over existing works, is £130,000, in £1 shares, which are taken by the vendor in part payment of the purchase money, £130,000 5 per cent. first debentures being offered for subscription at the price of 90. These are repayable at par on January 1st, 1948, and may meanwhile be redeemed at six months' notice at 105 per cent.

Central London Railway.—A special meeting of this company was held last Saturday for the purpose of authorising an increase in the number of directors, and for the election of Sir Henry Oakley as a director. The motion was adopted, and subsequently Sir Henry Oakley was elected chairman of the company.

Metropolitan Electric Supply Company.—The ordinary general meeting will be held on 29th inst., at noon, at Winchester House. The transfer register of the ordinary and new ordinary shares will be closed from 19th to 29th inst., both days inclusive.

Bournemouth and Poole Electricity Supply Company.—The first ordinary general (statutory) meeting will be held at Winchester House, Old Broad Street, E.C., on the 28th inst., at 2 p.m.

Eastern Telegraph Company, Limited.—The usual interim dividend of 2s. 6d. per share on the ordinary shares, free of tax, in respect of the quarter ended December 31st, is announced.

Brockie-Pell Arc Lamp, Limited.—This company notifies that the transfer books of the company will be closed from March 22nd to April 4th, 1898, both days inclusive.

TRAFFIC RECEIPTS.

The Bristol Tramways and Carriage Company, Limited.—The receipts for the week ending March 18th, 1898, were £2,503 8s. 4d.; corresponding period, 1897, £2,053 7s. 5d.; increase, £449 15s. 11d.

The Cape Electric Tramways.—The receipts for February were: Cape Town, £8,600; Port Elizabeth, £2,275.

The City and South London Railway Company.—The receipts for the week ending March 20th, 1898, were £1,030; week ending March 21st, 1897, £1,012; increase, £18; total receipts for half-year, 1898, £12,826; corresponding period, 1897, £12,818; increase, £8. Miles open, 3½.

The Dover Corporation Electric Tramways.—The receipts for the week ending March 19th, 1898, £117 17s. 5d.; total receipts to March 19th, 1898, £1,166 8s. 11d.

The Dublin Southern District (Electric) Tramways Company.—The receipts for week ending Friday, March 18th, 1898, were £403 4s. 6d.; corresponding week last year, £363 15s. 4d.; increase, £39 9s. 2d.; passengers carried, 68,513; corresponding week last year, 59,721; aggregate to date, £4,378 17s. 11d.; aggregate to date last year, £4,669 13s. 10d.; decrease to date, £290 15s. 11d.; mileage open, 8 miles.

The Liverpool Overhead Railway Company.—The receipts for the week ending March 20th, 1898, amounted to £1,316; corresponding week last year, £1,360; decrease, £44.

The Western and Brazilian Telegraph Company, Limited.—The receipts for the week ending March 18th, 1898, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £2,933.

THE NORTHAMPTON INSTITUTE.

This Institute was formally opened last Friday evening by the Lord Mayor and Lady Mayoress, and the Sheriffs. As we have already mentioned, the land upon which the magnificent buildings have been erected, was presented by the late Marquis of Northampton and by his son, the present Marquis. The value of this gift is £25,000, and the erection and equipment of the buildings has cost £80,000. There is to be a further outlay of £10,000, to £15,000 for completing the equipment. The money was provided by the City Parochial Authorities, the Technical Education Board, the City Companies, &c.

The Northampton Institute forms an important branch of the City Polytechnic, and is to supply the neighbourhood in which it stands with the same educational advantages as are afforded by similar institutes to other parts of the metropolis, *i.e.*, the Birkbeck Institute, and the City of London College.

The scheme was originated in 1891, and the full work, both educational and social, started at the end of September, 1897. An idea of the success which has so far attended the Institute, may be gained from the fact that there are already 1,500 members. Mr. Charles Dorman, chairman of the governing body, in explaining matters to the Lord Mayor on Friday, said that they had equipped 17 large workshops, and seven laboratories in addition to numerous social rooms, studios, offices, &c. He remarked that perhaps no other district in the metropolis has such a large number of manufacturing trades as Clerkenwell, and the Institute could not fail to benefit the numerous mechanical, electrical, and artistic trades. The cost of carrying on the work of the Institute is estimated at from £9,000 to £10,000 per annum. Lord Mayor Davies delivered a speech well worthy of the occasion, and among other speakers were Sir Henry Longley, K.C.B., Mr. R. M. Beachcroft, L.C.C., (who, referring to the gifts of the City companies, said that if it were not for those companies we should be 20 years behind in technical education) and Lord Alwyne Compton, M.P., acknowledged the thanks accorded to the Marquis of Northampton.

An inspection of the various departments was afterwards made, while a concert proceeded in the large hall.

Mr. John Ashford, A.M.I.M.E., is the head of the mechanical engineering and metal trades department.

The engineering workshop is equipped on the two long sides with hand benches fitted with various kinds of vices. Down the centre of the room there are the machine tools—comprising, at one end, a Universal milling machine, next to that a large drill and a group of lathes, forming excellent examples of English and foreign designs. Across the other end of the shop are the grinders, consisting of an emery wheel for general work, a Universal tool grinder, and a twist drill grinder. The emery wheel shaft is directly coupled to the driving electric motor, and the shaft driving the other grinders also drives the blower for the smithy in the next room. The whole of the power for the machine tools is derived from three different electric motors, so that only the small amount of shafting connected with the tool in use need be run at any one time.

There is a smithy and carpenters' shop, the machine tools in the woodwork room being driven by an electric motor. They comprise at present a band saw, pattern makers' lathes, and a grindstone, but there is room for further tools.

The boiler house contains two 100-H.P. boilers, one of the Lancashire type, the other a Babcock & Wilcox tubular type. The object in having two such different boilers side by side is that the students may have opportunities of making comparative tests of the different performances of the boilers under different conditions of working, and with different kinds of fuel. The steam piping on the top of the boilers is constructed of welded steel, and has been specially arranged for experimental purposes. It is such that either boiler may be used separately from the other or in conjunction with it. Injectors, as well as a feed pump, are fixed, and the stop valves are of different patterns, so that the students may have opportunities of inspecting and becoming familiar with the various designs in use. The steam raised is used for both heating and power purposes.

The power room for the joint use of the mechanical and electrical departments contains a 100 H.P. Willans and Robinson high-speed engine, coupled directly to a 63-kilowatt dynamo, which is used for lighting the building and for supplying the power to the various workshops and laboratories. From a large switchboard erected at one end of the room 24 circuits can be controlled. Another dynamo has yet to be erected, and this will be driven by a slow speed engine. The power from both dynamos is brought to the switchboard to a couple of omnibus bars, from which it can be delivered to any one of the 24 distributing circuits. In addition, alternating current supply from the central station of the Public Supply Company is brought to another pair of bars on the board, and from these bars any of the 24 circuits can have power given to them. The board contains the usual measuring instruments, switches, &c.

One-half of the instrument workshop is equipped for bench work, and has benches both for metal and wood work with the ordinary hand tools. The other half contains the power-driven machinery, consisting chiefly of lathes of various patterns, a sensitive drilling machine, polishing spindles, and a grindstone, the whole of the power for these being derived from an electric motor placed in the room.

The largest class that meets in this room is that for electric light wiremen, who are practised in the manipulation of all kinds of electric fittings of the most recent type, and the most modern methods of jointing and insulating the joints by vulcanising and otherwise. In addition there are important classes in electrical instrument making and in the brass finishing, special attention being given in the latter to repetition work.

A special feature of the drawing offices is the system of lighting, which is that of inverted electric arcs. The same system is adopted for the art studio.

Dr. Mullineux Walmsley is the principal of the Institute, and he is head of the applied physics and electrical engineering department, with Mr. C. V. Drysdale as chief assistant and senior lecturer, Mr. E. T. Martin as demonstrator and instructor in instrument making, Mr. K. Edgcumbe as senior demonstrator, Mr. W. R. Elliott as junior demonstrator and assistant mechanic, Mr. A. C. Jolly as lecture assistant, and Messrs Robins and Grew as junior assistants.

In the electrotyping room all the mechanical operations connected with electrotyping are dealt with. The whole process of preparing the moulds for the bath and of mounting and finishing the electrotype after deposition is carried through here, but the actual electrodeposition takes place in a separate room set apart for electrochemistry.

A room is being fitted as a laboratory for metallurgical chemistry, but the equipment is at present incomplete. It is intended, with a metallurgical laboratory, to be ready next session.

The junior physical laboratory is fitted for technical work in applied physics, and during the present session its accommodation has been strained by large classes in electrical engineering, and telegraphy and telephony. It has also been used for physical work in connection with the engineering and building trades sections. The equipment consists of the most recent types of testing instruments and experimental apparatus, and the various experiments performed by the students are of a thoroughly practical character.

In the senior physical laboratory, a good start has been made in the provision of delicate and standard instruments for important technical testing and experiments, but the equipment is not yet nearly completed. The chief work at present carried on in the room is testing in its most advanced branches, in connection with the advanced courses of electrical engineering and telegraphy and telephony.

The heavy electrical engineering laboratory is placed in the basement, and next to the "power room," already described. It is being equipped for the most advanced work in electrical engineering. The power for driving various continuous current dynamos and alternators is supplied by a 6 H.P. electric motor, whose speed can be altered through wide limits. This motor is directly coupled to a Ferranti alternator, and drives other machines by belts. A special feature of the room is, that rails have been sunk in the floor, so that the placing of a new dynamo or motor in position for testing purposes can be accomplished in a very short time. On the window ledges are acid-proof chambers for two small batteries of secondary cells, which will furnish large currents when required for testing instruments. A special table is being fitted up with very complete arrangements for the calibration of commercial electrical measuring instruments.

Next to the senior physical laboratory, a laboratory for electrochemistry is being fitted up. The equipment of the room is not yet complete, but there will be found specially designed tables capable of accommodating 16 students in the subject at one time. There are the usual depositing and cleansing, &c., vats, those giving rise to deleterious fumes and vapours being placed under a large hood, communicating with a shaft in which there is an electrically driven fan for carrying off the noxious gases. A special feature of the room is, that the depositing dynamo is directly coupled to an alternate current motor supplied with power, not from the dynamo room, but from the public mains, thus practically demonstrating to the electroplaters of Clerkenwell a method for utilising the electric mains now laid throughout the district for the purposes of their trade, although the currents directly obtainable from those mains are not suitable for plating work. In addition to the dynamo, there are secondary cells on the window ledges capable of giving large currents for plating purposes when the dynamo is not running, and from these cells conductors will be run alongside the vats, and also to the experimental tables, giving in all parts of the room a ready means of procuring currents suitable for electro-depositing.

THE GAS ENGINE AND ITS MISSION.

In view of the increasing popularity of the gas engine, the *Railroad Gazette* publishes a series of articles under the above head, in which are discussed the points of the gas engine. There are stated to be 100 makers in the United States, one quarter of whom own genuine works exclusively devoted to gas engine business. We need not follow the writer through the history and elementary descriptions.

While the ordinary initial pressures are 250 to 300 lbs. per square inch, the writer has met with compression to 96 lbs. and an initial pressure of 405 lbs., pressures which make a large demand on workmanship. In America, the latest engine is the Westinghouse, with two vertical cylinders in the smaller sizes and three in the larger engines. The latter have, therefore, an impulse every 240° of crank revolution, and are claimed to give a brake horse-power for 13 feet of natural gas. They govern partly by reduced admission and partly by missed explosions.

Governing is a serious difficulty with gas engines. The omission of explosions requires high speeds and very heavy fly-wheels, and demands a margin of speed between upper and lower limits of some breadth. By reducing gas admission the efficiency is so much reduced that while the Belfast engines used 24 feet of Belfast gas under best conditions, the consumption rose to 40 feet for one-quarter load. The compromise system hits somewhere between the two.

American practice in ignition tends to the use of the electric spark as perhaps more convenient if less economical than the ignition tube. For valves, American practice resembles European in its use of the mushroom or similar valve, but tends towards their automatic movement, so abolishing much outside gear and producing a simple looking engine. With automatic valves engines may be run equally well in either direction. There appears also a tendency in America to employ gas engines, not simply in small industries, but in large works for sub-division of power of the kind one looks for with electricity. Small steam engines are very wasteful. Small gas engines are not anything like so wasteful as compared with their larger brethren as are small steam engines. But there is still a radical fault in gas engines. They have no reserve of power beyond their economical rate of working. A gas engine underloaded is wasteful. Its economy improves up to the point where every possible explosive stroke is explosive. When an engine is fully loaded, with steam valve open to the full, it begins to run slow if any further load is put on it and by running slow it increases its mean pressure and decreases its resistance. But, with a gas engine, as with an elephant, every response is made up to the maximum, and beyond this the engine lies down, so to speak, and stops. The gas engine lacks staying power because it lives a mere hand to mouth existence. Between the gas engine which will not run overloaded, and the oil engine which stops if too lightly loaded, the internal combustion engine cannot be held to have reached the forefront of prime movers despite its economy. We do not think so much of the starting difficulty as the author before us. The starting arrangements of large gas engines are various. There is the reservoir of compressed air, the hand pump on similar lines, the explosive cartridge, and various other self starters. We have very little doubt ourselves that the large engines of the future will follow on the lines of the large steam engines and be started by small engines, which themselves can of course be started by a man, as usual with a small gas engine. Messrs. Hartley & Petit do use this system, and applied the little starting engine to the large gas engine for Mr. Arthur Porrit, of Birstall, which they put down to work with the Thwaite gas producer we have already described.

The various difficulties with gas engines have no doubt kept them in the background, even where the conditions have been favourable to the employment of producer gas. Gas producers, however, until lately, have not been successful for powers much under 100 H.P., but they are now on the market as small as 35 H.P., at which size they are about as large and not nearly so dangerous as a 35 H.P. vertical boiler. Statistics for Germany point to one gas engine for each 1,015 inhabitants, and the average power is 3·36 H.P. Engines are increasing at about 9½ per cent. per annum in number, and about 12 per cent. in their average power. The author gives the cost of power for the four prime movers, steam, oil, city-gas engines and producer-gas engines as ⅞ cent. per H.P. hour, 1½ cents, 2½ cents, and ½ cent. Oil in America comes out cheaper than city-gas by a larger amount than it does in England where gas is cheaper and oil is dearer, but producer gas ought to be as cheap in America as anywhere, and we should look to a considerable extension of producer gas plants.

The author holds that the objections he has advanced are not perhaps insurmountable. At the same time they have not yet been surmounted, and they must be grasped and appreciated before the position of gas power can be properly understood. We always have had a good deal of respect ourselves for the Clerk gas engine with its separate pump, and should like to have seen it a success. We think in large installations of gas power that the engines will have an explosion every revolution, that one engine will be set apart pumping up a reservoir of gas and a reservoir of air to flow into the cylinder and push out the exhaust, and that in this or some similar manner engines will do double duty for their size as compared with existing engines. The gas engine is yet far from perfect, but it is slowly improving and it has the very powerful argument of economy to push forward its interests. In the steam engine power is manufactured and stored in the boiler. There is always fire enough to suffice for a very considerable number of revolutions of the engine at full power, apart from other reserves. Besides this store of heat there is a mass of heated water in the boiler ready to give off energy should the demand for steam exceed for a time its production, and there is yet a store of ready made steam in the steam space to fulfil the same end, and when power has been manufactured there is still the fly-wheel to store a portion ready for immediate calls. The steam engine has four items of stored energy. The gas engine has but one, the fly-wheel. It has no mass of partly burned fuel ready to give off heat and to go into a state of more energetic heat production by the opening of a damper. It has no heat stored in water, and no store of elastic vapour. The movement of its governor orders the "stoking" of a fresh charge of fuel, its lighting up, combustion, and steam raising, and in the fraction of a second the fuel is lighted, consumed, the steam it raises is used and discharged, and unless the governor again asks for it, the fire remains out.

A consideration of these facts shows us that in the gas engine there is cut out a considerable duration of time between the shovelling on of fuel and the use of the steam generated by that fuel. This explains at once both the economy and the delicacy of the gas engine. In the economy of nature the food of to-day may appear as muscular energy to-morrow, or it may be later. The animal machine will run for hours on no fuel at all. It will run for days on less fuel than is represented by the energy produced. The gas engine is like what a horse would be that could not walk 10 yards without a nibble from its nosebag. This is not to argue that the engine is on wrong principles, but that the mechanical difficulties which hem it in are yet only incompletely solved.

THE TELEPHONE SYSTEM IN LONDON.

Conference of Local Authorities.

On Thursday afternoon of last week a well-attended conference of local authorities, convened by the City Corporation, was held at the Guildhall, to discuss the question of the telephone system of London.

The Lord Mayor, in opening the proceedings, said he did not intend to take any part in the proceedings, for it was a subject he did not really understand, but he welcomed the local bodies outside the City to the Guildhall.

After some preliminaries, Mr. A. C. Morton was elected to the chair, and said that was a conference of delegates representing the vestries and local boards of the metropolis, convened by the Corporation with the object of ascertaining the views of the local governing bodies in London as to the cost and efficiency of the London telephone service. Thirty-one boards and vestries, out of 41, as well as the City Corporation, had signified their intention of sending delegates, and 25 of these bodies had intimated that they had applied to the Treasury for an inquiry into the cost and efficiency of the telephone service in London, and all matters relating thereto. They were aware of the action taken by the late Commission of Sewers with a view to obtaining a cheaper and more efficient service. The late Commission, in 1895, after having ascertained the views of the telephone subscribers in the City, gave evidence before the Select Committee of the House of Commons, which inquired into the matter last year, but in consequence of the dissolution of Parliament the Committee had not sufficient time to report, and they recommended that another committee should be appointed in the next session to consider and report on the evidence already taken, and, if necessary, to take further evidence. No action had, however, been taken. Having referred to the recent action before the Railway Commissioners between the Corporation and the Post Office, the chairman said that the opinion of the Corporation was that the roads and streets in the metropolis belong to the people, and that they ought not to be given up to any trading company, unless under conditions which would protect the public. The Lord Mayor had handed him a letter which he had received, and that he would ask the Town Clerk to read.

Sir John Monckton then read a letter which the Lord Mayor had received from the National Telephone Company. This communication, which was signed by Mr. J. S. Forbes, as president of the company, began with an expression of doubt that the announcement of the conference could be correct. If it should prove that it had been made on good authority, it seemed to the company that what was to be done was like inverting the natural order of things. But probably the real meaning was that the resolutions were only to be put when the conference had before it some reliable evidence. In any case it was clear that the company was to be treated as defendants in a suit, and it would only be fair that they should be heard in the preliminary inquiries, and before being, so to speak, committed for trial. As president of the company, and in the interest of all concerned in the conference and its results, he desired to tender some points which he thought might be usefully borne in mind in any discussion on the subject. His colleagues and himself would be the first to admit that the telephone service as at present conducted left much to be desired, not for want of will on the part of the company, but for want of those reasonable facilities at the hands of the local authorities, without which it was absolutely impossible to conduct the business with the highest efficiency. It was singular that in this matter London, generally so advanced, should lag behind Manchester, Leeds, and many of the other large cities and towns, in which the companies had succeeded by agreement with the authorities in securing upon moderate and reasonable terms the necessary use of the streets for underground cables and wires, to the immense advantage of the users of the telephone, owing to the improvement in promptness and efficiency which had immediately followed. It was true that in a few cases such powers had been granted in disconnected portions of London. But apart from this, the company's network of wires, accommodating close upon 17,500 subscribers, existed upon sufferance, and was subject to constant interference and interruption by persons who, from caprice or other motives, inflicted heavy loss upon the company, and serious interference with the subscribers. Under such a condition of things, a perfect telephonic system was impossible. The letter went on to say that the recent inquiry held in Glasgow, raised points identical with those sought to be raised in London. That inquiry lasted 11 days, the cost to the company was over £4,000, to the Corporation it was over £3,000, and to a combination of would-be promoters of a competing system, nobody knew how much. They did not yet know what the report of the commissioner was, but it might be worth while to wait until his report was before entering upon another precisely similar inquiry. Having frankly admitted the present shortcomings of the service, Mr. Forbes desired to say something on the subject of charge, and in doing so, he would deal with the year 1897. The London area covered 609 square miles, and the number of subscribers at the end of the year, was 17,371. The average subscription was £14 10s., equal to about 5s. 7d. per week, day and night, including Sundays. It had been computed by the general manager that during the year there were 30,000,000 calls, involving as many answers, or 60,000,000 conversations, each averaging 200 words. Each conversation cost the subscriber about 1d. When it was taken into account that the company had to pay about 10 per cent. on its gross receipts for exchange business to Government, and was subject to heavy charges for wayleaves, he thought the charge of 1d. a message was very small. Comparing this with the cost of Post Office telegrams, he found that the 73,000,000 messages sent—the total for the United Kingdom—averaged 7½d., representing only 15 words. In conclusion, Mr. Forbes said if the conference thought it expedient to appoint a committee as a preliminary to further action, the company would be ready to place at their service all evidence and information that their experience enabled them to offer.

The Chairman: I am bound to say that the answer to that letter is in the second resolution.

The letter was then laid on the table.

Mr. Robinson (Kensington) moved: "That in the opinion of this conference of delegates representing the Corporation of London and the vestries and local boards in the metropolis, the present telephone service of London is both inadequate, inefficient, and costly." The position before them was that the Treasury had laid down that if the service was inadequate or inefficient it would grant an inquiry, and as they were agreed that it was inadequate and inefficient, they had a perfect right to ask for an inquiry.

Mr. Matthew (Stoke Newington) seconded the motion.

Mr. Trenner (Holborn) said that Mr. Forbes frankly admitted that the service was unsatisfactory, and so he had practically pleaded guilty, and should have no objection to being sent to trial. There were many complaints as to the lines; they were told the lines were engaged, and he asked whether they thought the line was always engaged, or whether it was merely a flippant answer on the part of the girls managing the telephone.

The motion was carried.

Mr. Pankhurst (Marylebone) then moved that: "In the opinion of this conference an inquiry should be held by the Treasury as to the cost and efficiency of the London telephone service, and all matters relating thereto, agreeably to the request of the local authorities of London." He had had a painful experience of the telephone. His business brought him into relationship with Glasgow and Manchester, and other places, and he was told the charge was only £8 in some places. It was all very well for Mr. Forbes to try and hoodwink them that the average cost was only £14 10s., but the average business man paid £20 a year, and that was quite as much as he should be expected to pay. He certainly thought they should have a service for £10 in London.

Mr. Savory (Stoke Newington) seconded the motion, and referred to the time the company took to connect a new subscriber.

Mr. Trenner called attention to the fact that two years ago on the occasion of the great storm, the service completely broke down, but although many subscribers could not use their wires for two, and even three months, no reduction was made in the subscription.

Mr. C. W. Tagg (Camberwell) said that having passed the first resolution, he did not see why they should not adopt No. 2. If they were all to give their experience of the National Telephone Company, and the language they had used, he thought it would be preferable to put the question at once. The only people who could hold a proper inquiry into the matter was the Treasury, and any person who wanted to give evidence could do so before them.

Mr. Alderman Smallman observed that while the Corporation threw blame on the National Telephone Company, Mr. Forbes threw all the blame on the local authorities, and it was therefore better to have an inquiry by the Treasury.

Mr. Knight (Limehouse) thought it would be well for the company to arrange at once not only with the City of London but with the whole of the metropolitan boards and vestries for the right of way under the streets, and the difficulty would then be ended at once.

Mr. Kimber (Wandsworth) asked whether it would not be well to suggest some remedy for the existing state of things.

The Chairman: I think the words "all matters relating thereto" covers everything.

Mr. Kimber: Very well. I am satisfied.

Mr. Kershaw (Shoreditch) said he would have liked to have heard something about the average charge of £14 10s. How that was done was by bringing in the private house charge of £10.

Mr. Paton (Limehouse) said he had been a customer of the company from the commencement, and having paid at first £20, he now paid £17. He thought the Telephone Company were fools in their own interest for not paying the vestries to allow them to lay underground wires. If they lowered the charge to about half they would get double the number of customers, and the cost of working would be little extra.

Mr. Haskell (Hammersmith) said that the company allowed local lines of £10, but they could not speak to the City.

Mr. Valentine (Poplar) gave the result of some correspondence with the company which his board had had. The company only wanted to pay a few pounds for laying the wires underground, and consequently the board would not allow them to do so.

Mr. Waycott (Paddington) said there was a much wider question as to whether the telephone should be municipalised. He thought the resolution should be amended, somewhat in that spirit, whether it should not be municipalised either by the London County Council or by the vestries.

Mr. Richardson (Hampstead) rose to a point of order. He took it that the question raised by the speaker was not within the scope of the conference.

The Chairman: The question, in my opinion, is entirely outside the scope of the conference.

Mr. Waycott rose to speak again, but met with considerable interruption, and refused to speak further.

The Chairman said they wanted a much larger inquiry in London than in Glasgow. It might cost a little more money, but it was the only way out of the difficulty. The Corporation had never played the dog in the manger policy. They had said: "You can have our streets on terms and conditions which favour the public."

The resolution was then carried.

Mr. Dewey (Islington) said what had impressed him was that that conference had not been so much a conference of delegates of local authorities as of customers of the National Company. Every gentleman seemed to attempt to use his powers as a trustee for the public, to enable him to get some private advantage by means of the telephone. He said, unhesitatingly, that if the National Telephone Company had no statutory powers, the local authority had no power to grant easement. He said that was knowledge of 30 years of the Metropolitan Management Act. The local authorities had the powers of surveyors of highways over the streets, and nothing more. He thought the company should get statutory powers, and then the local bodies could have the power of purchase after a fixed number of years. He moved—"That, inasmuch as the National Telephone Company is not possessed of statutory powers for placing mains, pipes, or wires underneath the streets of the metropolis, the road authorities have no legal right to permit the user of the streets for such a purpose, and that it is undesirable they should profess to give such permission until the interests of the public are duly secured by statute, as in the case of tramways and electric lighting undertakings."

Mr. Giles (Greenwich) seconded the motion.

Alderman Smallman moved as an amendment:—"That, inasmuch as the National Telephone Company is not possessed of statutory powers for placing mains, pipes, or wires underneath the streets of the metropolis, it is undesirable that the local authorities should give such permission until the interests of the public are duly secured by statute, as in the case of tramways and electric lighting undertakings, and subject always to the previous consent of the road authorities."

Col. Probyn (Strand) seconded the amendment.

Mr. Tapp (Fulham) observed that suburban parishes were worse off for telephonic communication than small villages in New Zealand.

Mr. Tagg said it was simply a waste of time to discuss the question whether the local authorities had power to allow the Telephone Company to take up the streets, for if the company had no power, the Post Office had.

The amendment was carried.

It was agreed that copies of the resolutions be forwarded to the Treasury, the Corporation of London, the London County Council, and the vestries and local boards of the metropolis.

Mr. Paton moved a vote of thanks to the Corporation of London for calling the conference, and the proceedings closed.

THE NORTHERN SOCIETY OF ELECTRICAL ENGINEERS.

The Practical Operation of Multiphase Currents. By T. Hawkins, Member. March 14th, 1898.

An electrical transmission of power plant may be divided into three main sections, viz., generators, motors, and line. In describing or inspecting such a plant, one naturally starts at the power house.

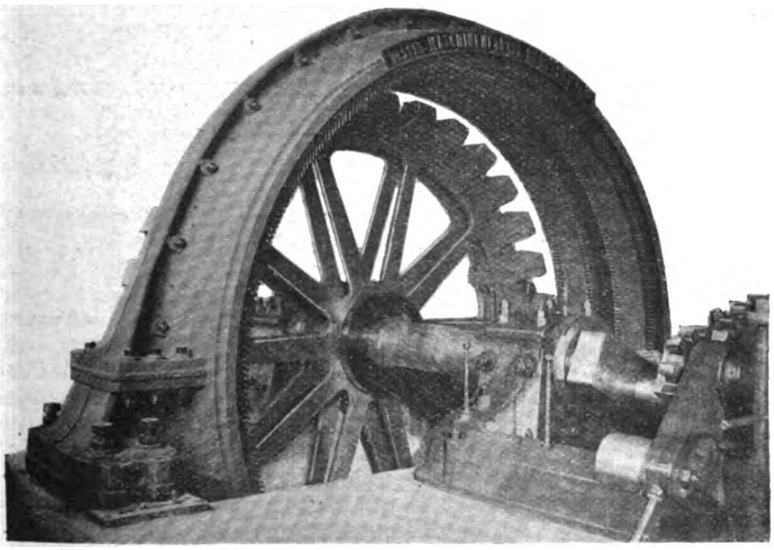

Fig. 1.—1,000-H.P. 3-Phase Generator Constructed by Oerlikon Company.

A multiphase generator is an alternating current dynamo, having its armature conductors grouped in such a manner as to give over a two-phase system two distinct currents differing 90° in phase. A three-phase generator would have its armature conductors arranged to give three currents differing 60° in phase.

For power plants where the distance between the generator and the various motors is not too great, and permits of a low pressure system being used (say 200 volts), a generator with a revolving armature makes a cheap and efficient type of machine. Where, however, the electromotive force exceeds 500 volts, it is better to have the armature stationary, which allows of increased facilities for securing and maintaining the insulation necessary for high voltages. In this case the field magnet is made to revolve, and the exciting coil or coils need not have a difference of potential exceeding 100 volts, even for very large machines.

The generators in use for the different plants described in this paper are of the "Inductor" type. This is undoubtedly a more mechanical piece of machinery than either of the foregoing. Its distinguishing features are that all windings are stationary, being fixed securely to the main frame, and that there are no brushes or sliding contacts whatever, the only revolving part of the machine being the iron or steel inductor. The armature consists of two laminated iron rings, enclosed by a cast-steel frame. This frame serves both as a support and as a magnetic path between the two laminated rings.

As will be seen from fig. 1, sufficient space is left between the two laminated rings for the insertion of the single exciting coil. The armature conductors are embedded in holes close to the inner circumference of the laminated rings. To prevent eddy currents, the pole pieces of the inductor are made up of laminated iron strips.

A multiphase induction motor has two distinct electrical circuits, viz., the primary and the secondary. The primary circuit, when supplied with multiphase currents, produces a rotary magnetic field. The action of this rotating field is to induce in the secondary circuit currents of low potential. It is the reaction between the rotating magnetic field and the induced currents in the secondary, which sets up a torque giving the required rotation. Either the primary or secondary can be designed to revolve.

If the primary circuit were made to revolve it would be necessary to fit it with sliding contacts, so as to connect it electrically with the feeding circuit.

One advantage attained by this method is, that it allows of easy insertion of a starting resistance into the circuit of the secondary; but as there is no difficulty experienced in inserting a resistance in a rotating secondary, if required, it is better to fix the primary and dispense with the sliding contacts. The stationary element is generally spoken of as the stator, and the revolving element as the rotor.

It is now the usual practice to have the primary or inducing circuit stationary, and to allow the secondary to revolve, so as to take advantage of the very low potential at which the currents are induced in the secondary circuit; also, because the circuit in this part is enclosed on itself, and is independent of the feeding circuit.

Small motors up to 8 or 10 H.P. are switched into circuit directly from the mains by means of an ordinary three-pole switch without the use of any resistances; but for larger machines, it is advisable to use starting resistances, either in the stator or rotor circuit, otherwise excessive current will be taken from the mains.

For large motors, not requiring to start against a heavy load, starting resistances can be used in the stator circuit. These resistances may be of two kinds: either inductive, known as automatic transformers, or non-inductive, which may be either liquid or metallic.

The maximum torque of a motor having a permanently short-circuited rotor, *i.e.*, a rotor which is not connected to an outside resistance is obtained when its full electromotive force is across the stator. If, however, the motor is not called upon to develop its maximum torque, a lower torque can be obtained by reducing the electromotive force across the stator terminals to such a point as will give the necessary strength of field for the required torque, the object of this being to reduce the starting current to a minimum and still enable the motor to get away.

The auto. transformer is of simple construction, and is similar to the "economy coil" used in alternating current arc lamps for obtaining a reduced voltage across the arc.

As an example, we will suppose the motor is designed to work on a 200-volt circuit; the transformer is divided into four parts, giving 200, 175, 150, and 100 volts. The motor may be connected to any one of these four voltages. We will assume it gives the required torque at 150 volts; a throw-over switch is required, one side of which is permanently connected across the 150 volts, and the other side across the maximum voltage of the circuit. To start up, the switch is put on the 150-volt side, and when the machine has attained its normal speed, it is thrown over to the 200-volts side, the automatic transformer being at the same time thrown out of circuit.

If a liquid resistance is used, it is made sufficiently large to prevent a sudden rush of current when the circuit is closed. The plates are then lowered into the liquid until there is sufficient electromotive force across the stator to start the machine. When the machine has attained its proper speed, this resistance is entirely cut out.

If it is necessary that the motor shall develop its maximum torque at starting, it is obtained by inserting a resistance in the rotor circuit. See fig. 2.

A starting resistance of this description is necessary, for the following reason:—When primary current is switched on, the rotary is, of course, at rest, and the lines of the rotating field are cutting the rotor conductors at a maximum rate, thereby inducing very large currents in the rotor, which has a very low resistance. These reduced currents in turn re-act on the stator field, and weaken it.

To obtain the greatest torque, we must keep up the strength of the stator field, and this is got by introducing resistances into the rotor circuit. Of course, the result of introducing the external resistance

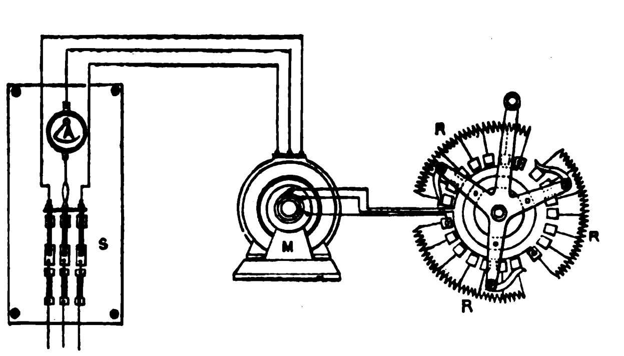

Fig. 2.

is to check the currents in the rotor, and so prevent them from unduly overpowering the stator field.

There is a certain resistance which allows the exact amount of current in the rotor to obtain maximum starting torque. The starting resistance should, however, be designed with resistance in excess of this, so as to prevent too great a current in the line when closing the circuit.

This variable resistance is connected in the rotor circuit in a three-phase motor, through three slide rings; the winding of the rotor and of the resistance box being in three circuits. This resistance is gradually switched out while the machine is running up to its normal speed. When this speed is attained, the resistance is short circuited and the three brushes lifted. The motor is now running quite free, without any sliding contacts or resistances; and for all constant-speed machinery these slide rings are only used for starting up.

I think I am right in stating that there is a much larger demand for constant-speed motors than for motors with a variable speed. It certainly is more economical to run the machines at the speed at which they are designed to give their maximum efficiency, and obtain, if possible, the variations by mechanical methods. Of course, this cannot always be done.

I have described to you the three ways which are commonly used for starting up multiphase motors. Motors up to 10 H.P. to be merely switched into circuit without resistance; motors of larger sizes requiring to give, say, twice their normal running torque at starting, to be switched in with the resistance in stator; and motors above 10 H.P., requiring to develop their maximum torque, to be fitted with sliding contacts, these sliding contacts to be used for starting purposes only.

Now, in a power plant calling for an aggregate of, say, 300 H P. in motors, it is likely that only a small number would be required to develop their maximum torque, and these could be supplied with a starting arrangement and slide rings.

We can suppose there are 20 motors below 10 H.P. absorbing a total of 130 H.P., four motors of 15 H P. with automatic transformers, two motors of 30 H.P., and one motor of 50 H.P., with slide rings, making in all 27 motors, three of which would be fitted with slide rings.

Here is a fairly large installation, requiring only three starting boxes amongst 27 motors, 24 having no sliding contacts whatever, and three having sliding contacts in use for starting purposes only.

If this were a continuous current installation, there would be, to begin with, 27 boxes; and to compare the motors, there would be 27 commutators, and about 150 carbon brushes and brush-holders.

The stator we may consider as corresponding to the field magnet of a continuous current motor. Both can be made reliable, and, as a rule, give little or no trouble. But it is to the merits of the rotor I particularly wish to call your attention. It is minus the commutator, brushes, and intricate brush work, and instead of taking the full potential of the circuit it has a difference of potential of only a few volts.

It is simply a laminated cylinder, with holes round its periphery, in which are placed solid rectangular bars connected at either end by a copper or brass casting, as per fig. 3.

The only part which has any insulation at all is the conductor, which has a light covering of tape, and this is only put on to confine the induced currents to the copper. This insulation gives a slightly increased efficiency, but should it fail the motor will still work, as the bars are already purposely short-circuited at certain points to the iron supports of the rotor.

Fig. 3 shows a rotor in which these bars are bolted directly to the end rings; no solder is used. The bolts have split spring washers under the nuts to allow of expansion and contraction of the metal, and still keep good contact. I may say that this particular rotor is one constructed by the Westinghouse Company.

You will notice, too, that there is no need for any binding wires or string. Not only is this part of the machine simplicity itself, but we have dispensed with comparatively high voltages, and as the machine is commutatorless and brushless, we can, once and for all, dismiss from our minds any anxiety as to sparking, even with sudden overloads, as sparking cannot occur unless the circuit of the primary or secondary is forcibly broken. The only limit to output is the heating of the stator on continuous overload. Wear and tear is reduced to the friction of the bearings, and as long as these get their proper supply of oil, the machine requires no other attention.

As an example, the multiphase motors at the General Electric Company's works, at Manchester, are only inspected once a month, and then only for the purpose of supplying fresh oil, if necessary.

The constant speed multiphase motor is a good regulator. Between no load and full load for an average size machine, the variation of speed is about 4 per cent.

The speed at which the motor runs depends upon the speed of the rotating field, and the speed of the rotating field is controlled by the number of the stator poles and the frequency which is being used in the installation.

At this point it would be as well to state that one cannot lay down a general law as to what frequency is best. As a rule, for motor work, it is not more than 60 cycles. The frequency is one of the two

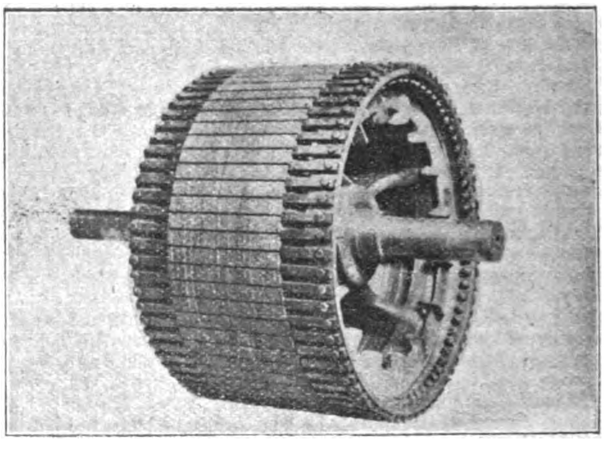

Fig. 3.

factors which control the speed, and it depends in a great measure on the class of machinery which is to be driven as to what is the best frequency to adopt. One would be inclined to keep it as high as possible, so as to keep down the weight, and therefore the price of the machine, as the speed varies directly as the frequency.

For instance, a motor giving 10 H.P. at 60 cycles and 1,150 revolutions per minute, would, at 60 cycles, run at 575 revolutions per minute, and give only 5 H.P.

The other way of decreasing the speed of the motor is to increase the number of stator poles; but this is not usually done, as to have too large a number of poles means great leakage, and, as a rule, the motors are, in the first place, designed with the maximum number of poles compatible with high efficiency.

I have stated that the multiphase generator need have no rotating windings at all; the only rotating part being a steel or iron casting. This reduces the attention and upkeep to a minimum, and I may here state that some installations which have been running in this country for two years, have, as yet, required no repairs whatever, and are practically as good to-day as the day they were put in.

(*To be continued.*)

THE RELATIVE IMPORTANCE OF CENTRAL STATION LOSSES.

A few sentences on the above subject are to be found among the editorials of the *Electrical World* of New York, dated January 29th. They point out in a brief and lucid manner what often escapes attention, namely, the relative importance of loss at the lamp terminals, for instance, as compared to the loss in the boiler room.

Bad firing or loss of heat by the chimney simply represents a waste of fireman's wages and coal. Then are traced the losses due to condensation in steam pipes and cylinders, which involve in addition to these increased boiler capacity to supply them; in turn, the losses in dynamos, mains, fittings, &c., are followed, each involving a corresponding increase of plant, until the lamps are arrived at.

It is not only astonishing but positively alarming, when one fully realises that the loss in efficiency in the lamps requires a proportional increase in boilers, engines, generators, mains, transformers, feeders, as well as wages for attendance, and also augment the losses in every part of the system where increased load means increased loss. Our contemporary's remarks end here, but we think they could have been carried much farther. In addition to all the above, we have to provide increased capital expenditure in plant, buildings, and mains, increased rates, rents and taxes, increased depreciation, repairs, reserve and maintenance.

The gentlemen who spend their time in securing every customer in every town where electricity works are established, and who often flourish certain letters on their cards which should guarantee their technical abilities, would do well to remember these facts. They should be most useful to the seller of a really good high efficiency lamp, and it would be worth his trouble to demonstrate to the engineer in charge of the electricity works in the towns he visits the truth of his assertions. We have generally understood from the gentlemen referred to, that their lamps were of the highest efficiency in the market, and a halfpenny cheaper than any other, and the halfpenny cheaper often sells the lamp.

It would afford an instructive evening's entertainment to many central station engineers to quietly think over what it means to them; the better and more efficient the lamps connected to his system the greater number he can supply with a given plant.

When he recollects how many tight squeezes he has had to "get over the peak," he will, perhaps, appreciate what it would have done for him had all his lamps been of the highest efficiency.

The generation and distribution of electricity has been reduced to a science, and it is unfortunate, in one sense, that the suppliers of electricity have no control of that part of their system most remote from the generating mediums where losses tell most heavily in proportion, namely, in the consumers' lamps. It follows that two towns similarly situated as to coal, water, and class of consumer with plants identical, may, from the fact that bad and inefficient lamps are used in one case and high efficiency lamps are used in the other show totally different results, and the true reason never be suspected. Little continuous wastes mount up to large sums when added up at the end of a year. We have known cases where the stopping of several small leakages at joints in the steam pipes has resulted in an appreciable lowering of the coal consumption; while the covering of the front of a boiler with non-conducting material and the stoppage of leaky glands have had the same effect.

True, these gains were small, but they were continuous and in time told up. Although the loss due to inefficiency in an incandescent lamp is small, yet it is taking place all the time the lamp is burning, and the number of lamps connected to the system being necessarily large, these infinitesimal losses soon mount up to a respectable amount, and begin to make themselves felt.

The losses in every step of the transformation process, from the latent chemical energy of the fuel to the light emitted from the lamps have been well thought out, and means taken to reduce them as much as possible; there are losses, however, which come under other heads, and the rectifying of which does not come under the control of the engineering staff, or we think they would be soon non-existent.

We refer to an item which might well come under the heading of wastes, for it no doubt influences, perhaps unconsciously, the efficiency of the whole system. We refer to the frequent changes taking place in the engineering staff. The man who puts coal on the fires, and the man who oils the bearings, are well paid for their labours; the policy being to get the best skilled labour in these departments, and to make the men contented with their posts, and thereby provide against their leaving.

Look a little higher up, and what do we find? Men who have spent years, and perhaps much money, to gain the experience necessary to enable them to fulfil the many and varied duties called for, and on whom the responsibility of the working and management of a most expensive plant, in many cases running into six figures, receiving wages, for we can scarcely call it salary, about equal to a foreman in a foundry, or a shopwalker in a draper's shop. We repudiate the idea that insufficient remuneration affects the performance of duty, yet we cannot help thinking the many changes we see week by week of engineers leaving one town to go to another when a slight increase of salary is attached cannot but have a detrimental effect on the economy of the system. In many cases we see men drifting right away into other channels where their experience commands more remuneration.

It surely holds good that if a skilled workman is to be made contented with his job and his services permanently secured, he must be suitably paid. The engineers should have a like consideration extended to them, and until this is done we feel sure that there will always be present a waste which has only one cure.

The man who has to give up social life, practically, if he does his duty, and devotes the whole of his time and attention to the duties of his office, cannot possibly do it complete justice if his mind is constantly occupied with the economical working of his household plant, if the term may be used.

ELECTRICAL DRIVING

MR. RAWORTH continues the correspondence in *Engineering* anent electrical driving, and assures Mr. Hirschmann, of whose letter we have already spoken, that 85 per cent. efficiency between indicated and electrical H.P. is not overstated, and claims that electrical engineers have ample proof that this can be attained and surpassed. He gives examples. A Holmes dynamo and Willans engine of 200 H.P. tested, by Prof. Kennedy, showed 85·7 per cent. in 1893. A Belliss-Crompton set of 200 H.P. at St. Pancras, tested by Prof. Robinson, gave 88·5 per cent. A Universal engine driving a Mordey alternator, was tested recently by Messrs. Kincaid, Waller & Manville to show 88 per cent., and included the power to drive air pump and exciter. Mr. Raworth points out that he allowed 65 electrical horse-power to produce 60 mechanical horse-power, so that he allowed 7½ per cent. loss on transmission and conversion at the motor—a narrow margin, it is true, but not too small if motor making is taken up with serious spirit. English made motors are, however, far too costly to permit of favourable comparisons with line shafts on the score of first cost, but American motors are now less than half the price of English motors of two or three years back, and great improvements may be looked for in this direction.

Mr. Raworth wants to make a national saving of 30 per cent. in fuel, and he does not doubt even the cotton spinner being able to see a profit and an advantage in ridding himself of belts, and of tall smoky chimneys. He suggests that electrical engineers may sit still if they choose, and watch the development abroad and in America, but he throws doubts upon the cordiality of the greeting of our grandfathers in the dim hereafter. This is very funny—"the dread of something after death," is to stir us now to "enterprises of great pith and moment." Three cheers for our grandfathers. But seriously, electrical engineers, and, indeed, all other engineers may wisely take Mr. Raworth in all seriousness. The cheapness of gas in this country has been a commercial set-back to the electric light industry, the excellence of our common roads has been against tramways of any kind, and not merely a bar to electrical progress. Moreover, the vested interests are so great in a settled old country, that it is difficult to get schemes taken up. We venture to say that, if new ventures in America demanded the same amount of preliminary energy to get them into shape that is required in old countries, the progress would be as slow as it is here, and Englishmen have not been idle even if they have not much to show. At the same time there is no harm done in reminding them that effort must be great and persistent. The mechanical work can be done if only it can be got to do. The difficulties are those incidental to any old-established country in which there are alternative methods. People who prate so very much of the American progress in electrical traction have failed to note that America has no common roads as we understand them. There may be cart tracks here and there, but the country is too new and too vast to have built a system of good roads.

For the American post office to carry on a parcel post by horse traction on the common roads, as is done here, would not be possible. Comparatively speaking, America has a very small mileage of railroads, and obviously the electric line has a larger and freer field for its growth than we have with our closer network of steam railroads as well as common roads.

But there are fields to be tilled abroad—in India and in China. In the latter country there must be a gradual leavening of returned Chinamen from California and Australia who are ready to ride on a car, and are in a position to expound matters to the stay-at-homes. China as a market ought to be preserved, or where are our engineering financiers to find play for their energies in the near future, before Africa is better developed?

NEW PATENTS AND ABSTRACTS OF PUBLISHED SPECIFICATIONS.

NEW PATENTS.—1898.

[*Compiled expressly for this journal by* W. P. Thompson & Co., *Electrical Patent Agents*, 322, *High Holborn, London, W.C., to whom all inquiries should be addressed.*]

5,501. "Improved apparatus for regulating the pressure on electric mains chiefly in connection with storage batteries." J. S. Highfield. Dated March 7th.

5,533. "Improvements in electric high and low tension fuse-heads for blasting purposes." W. A. Malson and S. R. Malson. Dated March 7th.

5,544. "An electric fog-signalling apparatus." J. Woods. Dated March 7th.

5,550. "Improvements in and connected with dynamo-electric machinery." M. T. Pickstone, R. S. Portheim, and A. C. Peebles. Dated March 7th. (*Complete.*)

5,560. "An improved holder for carbon and other brushes for electric motors, dynamos, and the like." A. L. Armstrong. Dated March 7th.

5,571. "Improvements in or connected with the application of electricity to marine propulsion." W. T. Carter, John A. Dawson, and T. Gray. Dated March 7th.

5,584. "Improvements in switches for electric glow lamps." A. B. Kistritz. Dated March 7th.

5,590. "Improvements in microphones." A. H. Skold. Dated March 7th.

5,596. "Improvements in electric arc lamps." S. Bergmann. Dated March 7th.

5,644. "Improvements in electric lamps for photographic and similar purposes." W. C. Cubbin and G. E. Johnston. Dated March 8th.

5,663. "Improvements in metallic conductors for protecting electric wires and cables." P. C. Middleton and F. Huggins. Dated March 8th.

5,672. "An improved electrical safety lamp for miners." H. H. Lake. (O. Siedentopf, Germany.) Dated March 8th. (*Complete.*)

5,680. "Improvements in telephone speaking tube and like receivers." H. A. Cutmore. Dated March 8th.

5,686. "Improvements in and relating to dynamo-electric machines and electro-motors." S. G. Brown. Dated March 8th.

5,693. "Innovation in electric lighters (pyrophore)." W. von Zabern. Dated March 8th.

5,703. "Improvements in electrodes for secondary batteries or accumulators." H. Pieper Fils. Dated March 8th.

5,704. "Improvements in electrodes for secondary batteries or accumulators." H. Pieper Fils. Dated March 8th.

5,705. "Improvements in the manufacture and production of electrodes for secondary batteries." H. Pieper Fils. Dated March 8th.

5,729. "Improved apparatus for the electric ignition in internal combustion engines." R. A. Miles. Dated March 9th.

5,750. "An improved form of automatic transformer switch." J. E. M. Stewart. Dated March 9th.

5,783. "Improvements in electric tram and railway systems." W. C. C. Hawtayne. Dated March 9th.

5,806. "Improvements in the manufacture of metal bases for electric incandescence lamps." H. H. Lake. (La Compagnie General des Lampes a Incandescence, France.) Dated March 9th. (*Complete.*)

5,810. "Process for making an electrical conductor and an insulating body of tar asphalt and the like materials." W. P. Thompson. (A. Lessing, Germany.) Dated March 9th.

5,823. "Improvements in and in connection with underground conduit electric railways." E. Heyl-Dia. Dated March 9th.

5,820. "Improvements in and in connection with incandescent electric lamps." E. Heyl-Dia. Dated March 9th.

5,863. "Improvements in incandescent electric lights and in processes therefor." W. L. Voelker. Dated March 10th. (*Complete.*)

5,912. "Improvements in electrical galvanic batteries." G. Laura. Dated March 10th. (*Complete.*)

5,934. "Improvements in conduits for electric conductors." J. J. Bate. Dated March 10th. (*Complete.*)

5,950. "Improvements in or connected with the application of electromotors to propulsion." W. T. Carter, J. A. Dawson, and T. Gray. Dated March 10th.

5,959. "Improvements in guards for flames or fragile objects, such as incandescence lamps, glass globes, &c." H. N. Moody and A. L. Davis. Dated March 11th.

6,014. "The springless contacts bayonet holder for electric incandescent lamps." L. Bertgues. Dated March 11th.

6,022. "Improvements in primary, voltaic, or galvanic batteries." P. Lafargue and E. Droult. Dated March 11th.

6,024. "Improvements in and relating to conduits for electric cables." W. Sykes. Dated March 11th.

6,025. "Improvements in and relating to draw and junction boxes for electric mains." W. Sykes. Dated March 11th.

6,026. "An electric drill." R. J. Crowley and C. H. Preston. Dated March 11th.

6,028. "Improvements in the method of and apparatus for the electro-deposition of metals." J. Holloway. Dated March 11th.

6,032. "Improvements in electrical or electro-magnetic therapeutic apparatus." O. Waratka and E. Sachs. Dated March 11th.

6,039. "Improved apparatus for electro-plating and polishing various small articles." A. E. Honey. Dated March 11th.

6,044. "Improvements in secondary batteries." A. Werner. Dated March 11th.

6,049. "Improvements in electrical measuring and indicating apparatus." A. U. Alcock. Dated March 11th.

6,058. "Apparatus for transmitting motion to a distance by means of electrical energy." Siemens Bros. & Co., Ltd. (Siemens and Halske, Aktien Gesellschaft, Germany.) Dated March 11th.

6,108. "Movement mechanism for electric apparatuses." P. Richter and T. Weil. Dated March 12th.

6,109. "Improved electric arc lamps." P. Richter and T. Weil. Dated March 12th.

6,110. "Improvements in blades for electric current collectors." P. Richter and T. Weil. Dated March 12th.

6,135. "Improvements in electric incandescence lamps." W. Nernst. Dated March 12th.

6,145. "Process for hardening and rendering tenacious the active mass of electric accumulators." R. von Babby. Dated March 12th. (*Complete.*)

ABSTRACTS OF PUBLISHED SPECIFICATIONS.

Copies of any of these Specifications may be obtained of Messrs. W. P. Thompson & Co., 322, High Holborn, W.C., *price, post free*, 9d. (*in stamps*).]

1897.

16,579. "Process of electro-glazing tile sections to form a plate for windows and the like." J. M. Ewen. Dated September 4th, 1897. This relates to electrolytic processes and devices applied particularly to securing tile sections of prismatic glass in the metallic frames intended therefor. In mounting prismatic glass sections, to form an entire sheet of glass for a window, such sections are arranged in a frame-like construction of thin metallic strips, which is immersed in an electrolytic bath. The current being applied, there will be an electro deposit along the metallic strips and between them and the glass sections, until finally a complete frame is formed and the glass or tile sections are secured together in one sheet. As frames and window openings are usually of great size, it is necessary to have a solution of very great depth in the tank; compressed air is forced through lead pipes at the bottom of the tank, which keeps the solution a uniform density, and thus stops all tendency towards irregular deposits on the foundation cathode skeleton frame between the lenses. 3 claims.

16,629. "Improvements relating to conduits for electric conductors." H. E. Newton. (The American Silesc Company, of 39-41, Cortlandt Street, New York.) Dated September 4th, 1897. This relates to improvements in conduits for electrical purposes with the object of providing a metallic race-way for the reception of either bare or insulated wires. The race-ways are constructed and the conductor may be drawn through them and consist of a suitable metal which is capable of being bent without breaking. They are made in lengths to correspond to the sections of a conduit in which they are located. They are packed at suitable distances apart from one another and from the interior wall of the conduit by means of powdered silesc; it being found that pure silesc has no tendency to absorb moisture, is a non-conductor of heat and is at the same time a perfect non-conductor of electricity. Wads of mica are provided at the ends of the adjacent sections of conduits and are snugly fitted around the race-ways and between the race-ways of the interior walls of the conduit, and provided with corresponding receding and projecting portions at the adjacent ends of the race-ways, for the purpose of breaking joint and to cause the adjacent faces of the wads to impinge against each other when the ends of the conduit sections are forced together. To connect these sections of conduit their ends are screwed on the outside and they are joined by a coupling nut. 5 claims.

THE

ELECTRICAL REVIEW.

VOL. XLII. APRIL 1, 1898 No. 1,062.

CONTENTS:

THE ELECTRICAL REVIEW.

Published every FRIDAY, Price 4d.

The Oldest Weekly Electrical Paper. Established 1872.

TO BE OBTAINED BY ORDER FROM ANY NEWSAGENT IN TOWN OR COUNTRY.

OFFICE:—4 LUDGATE HILL, LONDON.

Telegraphic Address: "AGEEKAY, LONDON." Code A B C.

Telephone No. 983 Holborn.

ALL Letters should be addressed to the Proprietors, H. Alabaster, Gatehouse & Co.

Cheques and Postal Orders (on Chief Office, London) to be made payable to Mr. H. ALABASTER, 4 Ludgate Hill E.C.

TRANSPORTATION.

IN his address to the Society of Engineers, Mr. W. Beaumont made a statement pregnant with meaning. Here is part of it:—"We are using old machines, of which two are required to do the work of one new one, and we go on driving them, and the shafting for them, year after year, making very small instead of larger profits, and thus investing what profits we do make in things one-tenth as pregnant with dividends as investment in the proper plant for the works that made them would be." This statement is expanded in various ways—mill owners, for example, paying double for coal, because an engine and boiler must not be thrown away for no better reason than that they will run another 20 years, and men are constantly refusing to renew plant that will return a 10 per cent. saving, though they will invest money as savings at 3 per cent. Confining his remarks in a narrow channel, Mr. Beaumont referred more particularly to the millions thrown away annually for lack of roads and means of transport.

The importance of transport is evident, when it is remembered that our railways have cost over a thousand millions sterling. Transportation, indeed, is a factor in the value of so many material things, which, indeed, frequently have no value except when far removed from their place of origin, as, for example, coal. To-day it often costs more to send goods from place to place by rail than it did by horses on the common roads, and is it not a disgrace that the Post Office finds it cheaper to use horse vans on the road than to submit to railroad extortion for parcel carrying.

It costs 9s. 6d. per ton to send goods the 35 miles between Manchester and Liverpool by rail. It can be done by horse traction for 8s. 6d., and by road traction engines for 2s. 11d. to 3s. 6d. per ton. But the roads would be ruined by such carriage of 15,000 tons weekly, and this is only one instance of the need of better facilities. But there are wanted more transportation facilities in other places, and the time has now come for the engineer to improve his own works. Improved roads would admit of better vehicles, and would give rise to new industries in motor cars. Railroads sprang up from faulty roads. To-day roads are no better than some of those made by the Romans, and we admit this by laying metal rails and admit tramcars upon these to the detriment of every other form of street vehicle. Two horses can haul on a tramway 42 passengers against 26 in an omnibus, and so we allow our roads to be spoiled by grooved rails We refuse to make a good road all over, but convert our roads into poorly managed railroads.

All possible underground and overhead means of travel in London are overcrowded, and it is now a first necessity to improve the ordinary roads. To do this, the light vehicles must evidently accommodate themselves to the roads that will stand the wear of the heavier vehicles of, say, 2 tons per axle. This is easier done than to make a road to stand the wear and tear of horses. The need is for better and more durable surface and substratum, and better methods of maintenance and repair, and a general minimising of the gradients. Axle load can be dealt with by using more wheels, so that tyres of yielding but good wearing material may be employed in place of steel edge runners. We need not dilate on the folly of constantly tearing up roads to get at pipes and other things. The subway, as in Northumberland or Shaftesbury Avenues, is too obvious an economy to require any emphasis. Macadam roads are not made as they should be, nor attended after making as they ought to be, to keep them up to the mark while the new surface is consolidating.

Road metal ought to be much more finely broken. Referring to the great economy of man's time effected by railroads, as compared with the old coach system, it is said there are still 106,000 horses at work in London alone. They are pounding the streets to pieces, and doing double the destruction of iron-shod wheels, and they are also the cause of much traffic of food, &c., some 20,000 tons a week in fodder and food alone, while an army of scavengers with carts and other horses are required to clean up after them.

At least one-third the total vehicular space is represented by the horse. Abolish the horse, and the streets at once become 50 per cent. larger, and many street blocks would be avoided. This is quite apart from the loss due to stoppage of streets for repairs due to the pounding of hoofs. From one to two hundred millions sterling spent on our roads would be an economy. The resistance of a railway per ton is 6 to 12 lbs.; for a tramway, 15 to 40 lbs.; on a good road surface of best quality, 25 to 30 lbs.; on good macadam, 38 to 60 lbs., and so on to 140 lbs. for gravel. Thus, a horse's efficiency on asphalte is double what it is on macadam, and so on. Similarly the resistance due to gradients is enormous, and jumps from, say, 45 lbs. on the level for good macadam, to 157 lbs. for a slope of 1 in 20. Yet many gradients are 1 in 8, or 1 in 10, which latter would demand 269 lbs. per ton. It is these gradients which make a motor vehicle demand a 16 H.P. motor, where one of 3 to 4 H.P. would suffice.

There are 1,200,000 draught horses in the country. Assume only 500,000, however, at £30 a year each for food and lodging, at least a third might be dispensed with, and save the country £5,100,000 a year, or, capitalised, £170,000,000 at 3 per cent., which is, therefore, what might be spent on the roads at a low estimate to save one-third of the horses employed.

As regards tramway traction, Mr. Beaumont seemed to favour steam motors or gas, because at present the Serpollet cars of Paris, and the Blackpool gas cars only cost about 4½d. per car mile and electricity costs 6d. But he thinks no small tramway can succeed properly. Tramways ought to be worked by powerful companies, as is now being done for electrical traction, when, perhaps, steam and gas systems may succeed.

We fancy Mr. Beaumont in this has not taken into effect the rapid acceleration which electricity makes possible and the economy of time thus secured. The general trend of his remarks may be summed up as a call for better road surfaces, so that road motor vehicles could be used, and easier gradients. He might have added a special word of commendation of our early railroad engineers, who aimed at directness and as close an approximation to levelness and no gradients as possible. Few know what is being saved by George Stephenson's determination to make the locomotive a success. He never over-rated its powers, but built huge embankments and made heavy cuttings so that it might have a level road.

We do not know if it is wise for an engineer to neglect finance altogether. It may save the labour of many horses to spend millions on the roads; but the man who has no horse would object to pay a sovereign for road tax, in order that his neighbour, who has horses, may save, say, £30 a year. There is clearly something to be urged against the abolition of the old toll gates, which, at least, taxed users directly. Mr. Beaumont's paper is suggestive. It is a little unpractical, but presidential addresses are perhaps better when not too closely argued. The subject of good roads is a very wide one. From the socialist standpoint their improvement could be undertaken, for no doubt large expenditure would return good interest to the community at large. But socialism is not at present within the range of practical politics, simply for lack of the only single essential to success, to wit, absolute fair dealing. With no horses, and with all tyres of suitable width for their loading, and of soft material, there is an evident perfection of road surface to-day possible, which would have great durability, for there would be no grinding wear. Such roads would imply an immense motor car industry. Doubtless this was the thought underlying the address.

The Gale and the Wires.

In a recent issue of the *Globe* attention is once more drawn to the interruptions which have occurred to telegraphic communication caused by the late gale. The cause, says that highly scientific daily, "is perfectly well known, and has repeatedly been pointed out in this journal. It is neither more nor less than our foolish system of employing overhead telegraph wires. For this there is nothing whatever to be said, except that it is rather cheaper in first cost than laying them underground." . . . "Other countries have underground wires, why not Great Britain? Years ago, even Switzerland managed to organise such a system, and was charging half-a-franc for messages upon which we in England are still paying a shilling. There should be no difficulty in the way of laying the trunk wires underground in this country." Such effusions as the foregoing are so common in the daily press and indicate such accurate knowledge of governing factors, that no doubt the Postal authorities will be at last ashamed of themselves and will proceed to abolish the overhead system and substitute underground work, as it can be done at a trifling expense, and will solve the question of uninterrupted fast-speed telegraph working and long distance telephony. It is, perhaps, needless to say that the so-called Swiss system is a pure imagination of the writer in the *Globe*, and that the idea that an underground system capable of carrying the enormous traffic which passes over the immense network of wires of the United Kingdom could be laid without difficulty, that is at a small expense, is simply ridiculous, let alone the fact that long distance telephony through underground work is impossible with our present knowledge. No doubt, however, the writer in the *Globe* knows all about the mysteries of "K. R."

Board of Trade Electrical Standardising Laboratory.—We have received a copy of the Board of Trade table of fees for examination or testing of electrical instruments for the measurement of resistance current or electrical pressure.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

A strong muster of central station men graced the last meeting of the Institution of Electrical Engineers on Thursday, March 24th, to hear what Mr. Hammond had to say as to "The Cost of Generation and Distribution of Electrical Energy." The proceedings were exceptionally interesting, inasmuch as the paper before the meeting was in the hands of the members, and the writer of the paper explained what was in it in an able discourse, lasting three-quarters of an hour. We all know Mr. Hammond to be one of the hardest workers in the profession, and were prepared for the clear and decisive character of his speeches. On Thursday evening he was at his best, and, from a few notes, gave all the leading points in his most voluminous printed paper in a telling fashion, which went down with the meeting as no reading could have done.

To briefly summarise Mr. Hammond's remarks is to index his paper, and it is worth while to do so under the circumstances. Firstly, he pointed out the difference between local authorities and companies, as regards the location of salaries and wages in the Board of Trade form of accounts; then he stated that these accounts have been systematically kept since 1890, and expressed the hope that the time will come when the Board of Trade will publish the figures sent in according to statute. The usual method of dealing with the quantity of electrical energy turned out is to take the costs of the unit delivered to the consumer, although some would prefer, as fairer, that the units should be taken as they leave the works.

The editor of a well-known contemporary has said that the reduction of cost of electrical energy is always to come. It may be replied that the cost to the consumer is even now one-third of what it was in the earliest days of public supply, while any such statement bearing on the actual cost of production can be easily refuted by perusal of the figures contained in the paper.

Mr. Crompton's paper of 1894 showed what had been and might be done, and further evidence of reduction in cost was given by such figures as have been obtained year after year by the Westminster, Manchester, and Leeds stations, proving conclusively that the tendency of costs is always to decrease. Ideal costs could be obtained by taking the lowest of the respective items as they now stand; while at Edinburgh, Leeds and Manchester, figures closely approaching Mr. Crompton's ideal figures have been obtained with much lower outputs than Mr. Crompton allowed.

Mr. Hammond then considered the factors that affect cost, such as:—

1. Output, the leading factor.
2. Load factor, the next important after output.
3. Reliability of plant, the general smooth running of things.
4. Engineer factor, the ability, assiduity and earnestness of the responsible engineer or engineers.
5. Efficiency of plant, as affecting consumption of fuel, &c.
6. Efficiency of distribution, as affecting outside losses, &c.
7. Cost of fuel, &c.

We have now an approach to the figure given by Mr. Crompton as a prophecy, that the cost in London would fall to 1·32d. per unit, and Mr. Hammond ventured to add that, when the output *does* reach 5,000,000 units, we shall see the cost as low as 0·75d. per unit.

Major-General Webber then opened the discussion by expressing his desire to say that all felt that there are individuals on this earth to whom we should like to be introduced, and that he was then introduced for the first time to one whom he had been very anxious to meet, "Chesterfield Junior." While he did not doubt that the statistics of this gentleman were quite as accurate as other statistics, still he thought that from the way they must be compiled they could not be of much use to the engineer as an engineer. For example, from the respective positions of various companies in the coal statistics in the paper it may be well argued that the order of merit shows completely how unreliable such figures are in forming an opinion. In short, that these figures to the engineer, however valuable they may be generally, are nothing more than suggestions; outside the gentlemen interested he thought no one could tell the reason for the particular order in which the various concerns fall. Further, it might be of use, however, if tables were prepared bringing down the figures to a uniformity by giving the calorific value, &c. Losses unaccounted for might also be classified, as by a heavy expenditure on copper, losses by resistance are minimised; some systems embody storage, and so many points have to be considered, that if everything were taken into account the results might come out in some other way to that at first obvious.

Mr. Crompton felt obliged to Mr. Hammond for his paper, as he had at recurring periods of three years written papers on this subject, and in this case Mr. Hammond had done the work for him. Anyone who knew the trouble and labour involved in the preparation of such a paper must be wild to hear it spoken of—as had been the case—as a compilation. As regarded the paper itself, he did not wish to say anything on points on which others might speak, but from his special experience he would emphasise the importance of investigating details of costs and losses, and Mr. H. W. Miller, nearly 10 years ago, adopted such analysis, being thus almost the father of weekly returns. The very great advantage of the Board of Trade returns was the arousing of the sporting instinct of the race, where central station supply was concerned. Prof. Kennedy, and many others, frequently suggested improvements in the method of displaying and arriving at the figures given in *Lightning's* tables and similar summaries of the technical press, that the race for honours might be a fairer one, bringing out as far as possible the merit of the engineer, but where conditions differ widely, it is very difficult to do so. He knew the difficulty, as in his last paper he attempted, by a knowledge of the calorific values of different coals, to arrive at a fair comparison, but was told that the resulting figures were his figures, and he admitted this. It was extremely difficult to bring things to a level. Engineers do not often have control of the management, and they cannot control the local authorities. Local taxation sometimes is very heavy, and may even now reach a value of two-thirds of the cost of coal; as times goes on, the two curves will cross one another.

After some remarks on the coal bill and its effect on the cost per unit, Mr. Crompton went on to say that a low coal bill is not of much credit to a station if extinctions frequently occur; that it is a suicidal policy to restrict the generation to a single station, and it is better to have two or more stations for a large supply. This is a little more expensive, and large London companies with multiple stations cannot be fairly compared with other systems, such as Brighton, worked from a single station. Quite recently there have been a good many smashes, and a point he attached importance to was the unreliability of directly generating at very high volts, as, if steam pipes break, bang go your coils. Such machines will not stand large quantities of escaping steam with impunity.

He had proposed the word "load factor," but the present use of this term was not quite satisfactory, and although his present proposal was rather complicated, he thought it more useful; that is, to take the number of hours per year that the plant would have to run to give the actual output—not a difficult thing to calculate.

Then low costs are due to the men controlling works. It is most important to get the very best men, and he would wish some means could be found to give the real representative order of merit, so as to show who really are the best men. Continuous publication of results is developing a race of highly skilled organisers—men who must be well paid, and will not be obtained for the remuneration of a mere clerk.

Mr. Wordingham thought the labour of preparing the paper must have been enormous, and as an evidence of the care taken in working out the figures, Mr. Hammond, he noted, had not overlooked the fact that last year was leap year. He thought it rather a mistake to leave out of sight capital cost, and the charges due to this often amount to half the real costs of production. Load factor is, after this, the real thing affecting cost. Ideal costs may be rather misleading, as electricity supply may be combined with other work. Also, there is a danger of competition being carried too far, and everything being sacrificed to low figures. He then referred to the low charges made at Manchester and Brighton, and urged the putting aside of a certain sum periodically to depreciation. He stated that he should personally be obliged to any contractor who would tell him actually the upper or largest size of unit actually to be obtained.

Prof. Forbes considered the curves of very great interest to all. After some general remarks on the desirability of limiting the use of curves and figures to the obtaining of facts and arguments which could, without error, be obtained from them, he pointed out that not only did the cost per unit fall with lapse of time from the start of a work, but also with output—which rose as time went on. Part of the reduction may be due to improvement in plant and methods, and part only to increased output.

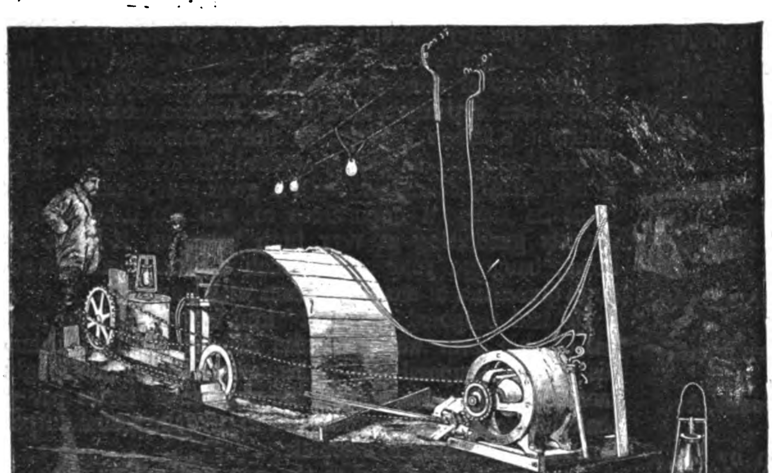
Mr. Grimshaw explained a diagram he had prepared, showing that at the Eccleston Place works of the Westminster Company, he had got down to 4·75 lbs. of coal per unit with exceptionally good loads, and had reached 4 lbs. on a 3—11 p.m. shift in winter, and considered it improbable that very much lower figures would be reached for some time to come.

Prof. R. H. Smith thought that Mr. Hammond's estimate of reduction of cost with output was exaggerated, as workmen and managers would expect some increase in greater proportion than seemed to have been allowed. It is also always a question of incidence of interest and depreciation, against decrease of working cost on the other side, as by spending capital the working cost can be reduced.

At this stage the discussion was adjourned until next meeting.

ELECTRIC TOWBOAT IN A SEWER.*

The city of Worcester has a large sewer 18 feet wide and 13 feet high. The sewage of the city is treated chemically to render it fit to flow back into the Blackstone River, so that it is desirable to separate the storm water from the sewage to lessen the expense of the chemical treatment.



In order to accomplish this end a smaller sewer, 6 feet wide and 4,000 feet long, is being built inside the larger one, utilising the bottom and one of the sides of the sewer. A cofferdam is constructed to enable the other wall of the sewer to be built, and in order to deliver materials to the workmen an electric scow was rigged up, which has been found very satisfactory. Electricity is also used to light the sewer, to operate ventilating fans and to work electric pumps. All of the lighting and power are generated on the premises in a small building outside the sewer. About midway between the ends of the sewer a small dock has been constructed and the materials are delivered to it by an incline through a hole made in the top of one wall.

The towboat is a catamaran 22 feet long and 5 feet wide. Each of the small boats is 18 inches wide. In the middle of the catamaran is a small paddle wheel box which is to prevent splashing. This is driven by means of sprocket wheels and chains which are connected with an electric motor of 2½ horse-power. At the stern end is a rudder and controller, so that one man can operate both. Only one electric boat is used. It tows six scows, which have already handled 12,000 bricks, 50 barrels of cement and 100 barrels of sand daily. The double trolley system is used, the wires being hung from insulated brackets secured to the top of the arch in such a way that a trolley can be run on it. A scow is also fitted with a centrifugal pump which is used for pumping out the cofferdam, and it is driven by another motor of 14 horse-power. The application of the electric towage to sewer construction is novel, and the results obtained are most satisfactory.

The electric scow was designed by Mr. Harrison P. Eddy, Superintendent of Sewers, Worcester, Mass. Mr. Robert N. Kendall is the assistant in charge of the electrical work.

* *Scientific American.*

CONDITIONS OF CONTRACTS.

We have several times lately referred to the onerous and often unfair clauses of specifications which are enforced against contractors. As we write, we have before us several specifications, from which we propose to select a few samples of clauses which, in our opinion, cannot be fairly upheld.

For example, in a clause for testing materials, the contractor is required to supply, free of charge, all labour and testing apparatus, and the tests are to be made when and how the engineer may direct. Without doubt the engineer ought to have the power to specify tests, but why should the contractor be exposed to the cost of finding apparatus and labour to his own possible undoing. This clause does not appear satisfactory, because it is not sufficiently rigid, and presents a difficulty in estimating the price to be put in. A personal knowledge of the engineer and his testing idiosyncrasies might be sufficient to give a great advantage to one contractor over another, while the lack of such knowledge might put a contractor to an unexpectedly large expense. Tests should, therefore, be standardised where possible, and an aggrieved contractor should have an appeal to an unbiased outside authority.

Under the head of power to vary works we consider it eminently unfair that a contractor should be paid under schedule of prices only. What of materials rendered useless by the variation? Is the contractor to have no recompense for his time and trouble, but simply be paid perhaps a few pounds on a schedule rate which was priced for amounts 50 times larger than those involved in the alteration.

In public work the item of watching may prove serious, so also may the contractors' responsibility for accidents even when caused by following the engineer's instructions. An engineer demands something to be done, perhaps, to expedite work; the contractor is obliging and does not wish to object, or, if he do object, he may become liable to penalties at the sole option of the engineer, and then when an accident happens the contractor bears it all.

There is a clause as to daywork in one specification before us, to the effect that daywork must be sent in not later than the next day after the time was made. There is nothing unfair in this, and contractors ought to be very stringent on this point. We have known where a contractor was easy and was anxious to help on work, and neglected to divide off the daywork from contract work and lost the whole of it amounting to over 10 per cent. of the whole work. Contractors find a difficulty with workmen. It is almost impossible to get the average working engineer to keep time separate on day and contract jobs. Workmen are hopelessly unintelligent in this respect, and if pressed to keep the time feel aggrieved as though they were being doubted. We have seen a good tradesman fairly dance with excitement when pressed to keep a time record on jobs, and end up by asking for his—money, and departing. Engineers who are intelligent and see no difficulty in keeping time separate, fail to appreciate the position of a contractor who has workmen to deal with. Take that honest man, the bricklayer, who shatters his health in disposing of a couple of hundred bricks daily. When these men are requested to hurry a job along down go their trowels and off they troop to the pay office, and between slow work and no work the contractor does not know how to meet the demands of the engineer for more rapid progress. *Apropos* of the recent *fiasco* at Bradford, there is a good clause before us, to the effect that no alternative scheme shall receive consideration. At Bradford, we presume, this was not a clause, and an alternative scheme was considered, and it ought not to have been in the absence of a special proviso to that effect. Alternative schemes either should be invited or should be specially barred out.

In another specification we find a particular type of boiler is demanded, and its evaporation per hour is laid down when using steam coal hand fired, both in the gross and per pound of coal. Now this is open to many objections. The engineer ought to fix the size of the boiler if he can fix its maker. One contractor may supply a boiler that is too small; he may make an error. True, he could be made to put in another boiler to do the specified duty, but this is not the object of employing an engineer. It is the engineer's duty to avoid disputes, not to lay traps for mere contractors.

The same engineer who specified as above, also specified for a gas engine to run at an absolutely steady speed of so many revolutions per minute. He specified a make of engine which governs by cut-out explosions. How then could he expect to get a steady speed of 160 or 190 revolutions when the cut-out is effected by speed variation. "Absolutely steady" are the words used, not sensibly steady; but further on it is provided that the speed variation shall not exceed a given allowance. Why first have asked for an impossibility, and then have toned down. These tonings down are apt to be extended by contractors perhaps too liberally to other clauses.

In yet another specification the contractor is under penalty to complete at a date given, and the engineer has the right to delay delivery or erection without extra payment, and the contractor's only benefit is to be an extension of time at the option of the engineer.

There are all sorts of claims which may be enforced against the contractor even to delaying work, and yet enforcing the penalty for non-completion by given date. We should doubt whether, under such circumstances, a court of law would allow a penalty to be enforced, but here again is that loophole for dispute and legal action which an engineer should avoid, which he is paid to avoid in truth.

This is a point on which we would like to insist. It is all very well to treat contractors as so many mere money grubbers. Contractors have their retort upon engineers, many of whom are not free from the reproach of making little jobs into big ones for the extra commission thereon. But whether contractors are all that many specifications would seem to imply, or whether they are not, a specification is intended to be a document that shall obtain justice all round. At present the aim of some specifications seems to be to place the contractor in a position to bear the brunt of any possible mistake or oversight on the part of the engineer, so that the engineer's paymaster may not be called on to pay for such oversight or error. This is unfair to the contractor. Of course, in the long run, the cost of these things comes upon the customer, for the contractor adds for contingencies, or in other ways increases the amount of all his tenders to cover such items. At the same time if such clauses could be eliminated, and contractors could rely upon fair treatment, all work could be taken at narrower margins and really just specifications would carry weight and could be easier enforced.

In one specification only do we find a bonus for earlier completion as well as a penalty for late completion. This is fair, but it is not fair to delay work and allow nothing for delay. A contractor is not necessarily wealthy. He has provided for delivery of goods and often wants payment to meet his liabilities. If compelled to obtain an overdraft he has got to pay several per cent. for the accomodation, and his banker only then grants it if he is sure of the final money. The very delay in work may be weakness and may stop a contractor's overdraft. Power to delay work irresponsibly, especially where the contractor has hurried goods forward to avoid penalty, is grossly unfair. As an American writer pointed out lately, it demoralises the workshop to see push goods lying waiting delivery after proper date.

The very presence of unfair clauses emboldens the unfair contractor to encroach, for too harsh a document enlists sympathy with him, and as juries were wont to convict sheepstealers of manslaughter to save their lives, so will contractors escape just penalties if held liable to unjust punishments.

It is not only in commercial clauses that we find items that are difficult to consider. What, for example, are we to think of an engineer's demand for gas engines to secure the highest economy and the minimum speed variations, conditions inimical to each other, the one demanding a system of governing differing from that demanded by the other?

Why, too, should a contractor be made responsible for the efficiency of producer gas supplied to work his gas engines, and be compelled to bear the expense of proving the gas quality to be wrong? If there be a doubt as to producer gas, a holderful could be made and its quality ascertained, and the engine run upon this. Producer gas must be fairly bad if a gas engine cannot work with it. There might be a standard gas, one that should not contain less than, say, 30 per cent. of combustible.

In reading through many specifications for all manner of work, it occurs to us that it is to the credit of our engineers and contractors generally that matters go as smoothly as they do. But specifications are usually so outrageous, that when a contractor goes to see plans and read specifications, he pays little attention to the most objectionable clauses. We have seen an inexperienced man with no knowledge of these matters, when confronted with objectionable clauses, put on outrageously big sums to cover them, to his own undoing and the loss of profitable work. Of course, such a man ought not to see such specifications, but the question arises, Should such things to be? Is it not possible to secure good work with more rational and standard clauses? The trial is being made. Let us hope success may attend it.

THE EFFECTS OF TENSION AND QUALITY OF THE METAL UPON THE CHANGES IN LENGTH PRODUCED IN IRON WIRES BY MAGNETISATION.

Mr. Byron B. Brackett has recently published in the *Physical Review* (America), Vol. V., No. 5, an account of the results of a long series of experiments on the subject of the title, with special reference to the effects of tension upon the phenomena. The experiments have been carried out with great care, and values of the different quantities involved very completely recorded. Tests are reported on piano wire in its natural condition under two different stresses, 658 and 1,949; on annealed piano wire under three different stresses, 62, 699, and 1,949; and on soft iron wire under four different stresses, 48·3, 430, 752, and 1,720; stresses being in all cases measured in kg. per sq. cm. The diameter of the piano wire was 1·25 mm., and of the iron wire 1·31 mm. Round the vertical stretched wire as an axis were arranged three pieces of apparatus. The first attached to the wire at two points was an arrangement of levers carrying a tilting mirror for observing on a scale the changes in length of the wire. The movement observed on the scale was 25,000 times the change in length of the wire. Round this was a cylindrical jacket of circulating water, designed to prevent, as far as possible, any change in the temperature of the wire by radiation from the magnetising coil; and outside this was the magnetising coil itself. Both these last pieces of apparatus were supported quite independently of the wire. The maintenance of a steady temperature was very important, as the largest magnetic effect observed in the series of experiments is about the same as would be caused by a change of ·3° C., and even with the water jacket the temperature changes are said to have been very inconvenient. For the details of the apparatus, which had been used by two previous observers, we may refer our readers to the original paper, and confine ourselves to the results obtained. The quantities observed or calculated at each stage of the magnetisation were the following:

1. The extension or contraction $\pm \frac{d\,L}{L} \times 10^7$, called E_T, when the magnetic force was applied, with B the magnetic induction, I_T the magnetisation, and H the magnetic force.

2. The same quantities with the magnetising current interrupted, viz, the residual extension, or contraction, $\pm \frac{d\,L}{L} \times 10^7$, called E_R, and I_R the residual magnetisation.

The course of taking the observations was as follows:—Starting with the wire demagnetised, a small magnetic force was applied and E_T and H noted. The magnetising current was stopped and E_R noted. A stronger current was applied in the same direction as before, and E_T and H again noted. The current was again stopped and E_R taken. This course was followed up to the highest magnetisations employed. Another series of observations was afterwards taken with increasing reversals, and a secondary coil in circuit with a ballistic galvanometer, to obtain the values of B corresponding to the values of H previously employed. I_T and I_R were calculated from the B H figures.

The numerical results are given in tables, and plotted in diagrams. The five sets of results obtained from the steel piano wire, hardened or annealed, and under different stresses, give curves of very similar character, and we reproduce one as an example. In every case the magnetisation under the magnetising current was raised to about 1,400, with a value

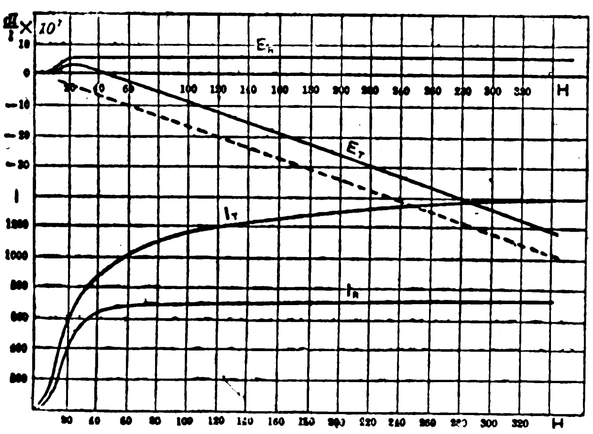


FIG. 1.—ANNEALED PIANO WIRE; TENSION 699.

of H about 340. The two curves giving the values of I_T and I_R, *i.e.*, of the intensity of magnetisation with the magnetising current, and after the current has been interrupted, are of the usual character, and call for no special comment; but those giving the values of the extension and contraction of the wire, drawn on a large scale, are of considerable interest. Comparing the curves (fig. 1) of I_T and E_T plotted to H, it is seen that no extension was observed till a considerable magnetisation was attained—E_T does not leave the zero line till $I_T = 9$. The extension soon attains a maximum when $E_T = 2·84$, and $I_T = 81$, and then diminishes, quickly changing to a contraction. The curve of E_T then follows a descending straight line which shows no sign within the range of experiment of a minor limiting value.

Comparing the curves of I_R and E_R, also plotted to H, it is seen that E_R remains zero till a certain magnetisation is attained, but begins to have an appreciable value at a lower magnetisation than E_T, the curve leaving the zero line when $I_R = 26$. The value of E_R then increases to 5·4, when $I_R = 580$, and retains the same value through the rest of the experiment, although I_R continues to increase throughout very slowly after a value of 700. The author points out that the curve of E_T appears to represent the sum of two quantities, first, the curve of E_R, and second, the dotted straight line drawn in the diagram (added by us to the author's figure), and it is suggested that the change in length is the sum of two effects: an extension due to the magnetisation, represented by the curve E_R, and a contraction directly proportional to the magnetising force, or perhaps to its excess over a certain small amount. In considering this very interesting suggestion, it should be borne in mind that the maximum contraction observed in any of these experiments on piano wire only amounted to $\frac{1}{2000000}$th part of the length. The experiments on these wires under different stresses

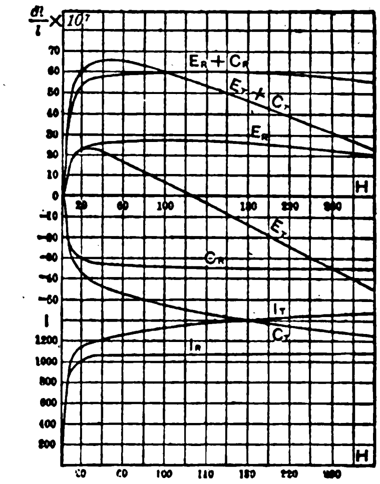

FIG. 2.—SOFT IRON; TENSION 430.

showed that an increase in the stress has no effect on the position of the dotted line, but tends to bring the curve of E_R nearer to the zero line, and the point where it first reaches its maximum nearer to the origin.

The reduction of the experiments on iron wire is more elaborate, but the results are very similar. Acting on a

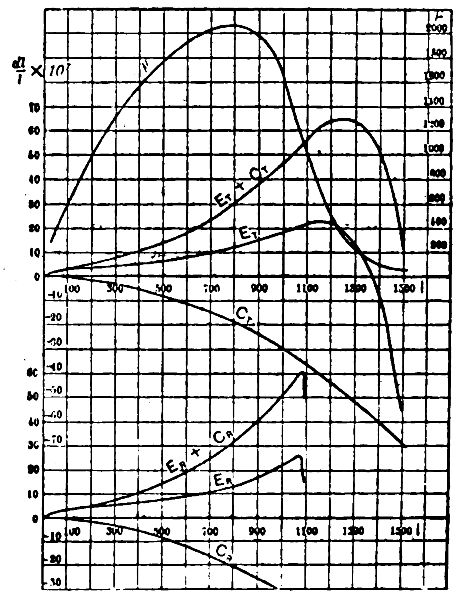

FIG. 3.—SOFT IRON; TENSION 430.

suggestion of Prof. Rowland that the induction, B, must produce a mutual attraction between the elementary magnets, and consequently a compression proportional to $\frac{B^2}{8\pi}$ (or in the case of residual magnetisation to $2\pi I^2$), divided in each case by Young's modulus. The values of these compressions, called C_T and C_R respectively, are also plotted. The curves lettered $E_T + C_T$, and $E_R + C_R$, are drawn giving what may be supposed to be the total extension due to the magnetisation, independent of the compression C_T or C_R.

Figs. 2 and 3 give the results of the investigations on iron wires under a tension of 430 kg. per cm. plotted for H and I respectively.

In fig. 3, the near equivalence of the curve E_T, to a combination of the curve E_R with a straight descending line, is well seen. The effect of increased tension in lowering the curve E_R without affecting the position of the descending line, was found to hold in iron as in piano steel.

Explanation of the Tables and the Notation used in the Tables and Plates.

H = the magnetising field.

$E_T = \frac{\text{change of length}}{\text{length}} \times 10^7$ while H is on.

$E_R = \frac{\text{change of length}}{\text{length}} \times 10^7$ after H is removed.

B = total induction or $4 \pi I + H$.

I_T = magnetisation of specimen with H on.

I_R = magnetisation of specimen with H off.

μ = magnetic permeability or $\frac{B}{H}$.

$C_T = \frac{\text{change of length}}{\text{length}} \times 10^7$ that would be caused by a mechanical pressure $= \frac{B^2}{8 \pi}$.

$C_R = \frac{\text{change of length}}{\text{length}} \times 10^7$ that would result from a mechanical pressure $\frac{(4 \pi I_R)^2}{8 \pi}$.

If these compressive forces actually exist, then the values of E_T and E_R computed from the observed changes are too small by C_T and C_R respectively, and

$$E_T + C_T = \text{the real } \frac{\text{change of length}}{\text{length}} \times 10^7 \text{ with H on.}$$

$$E_R + C_R = \text{the real } \frac{\text{change of length}}{\text{length}} 10^7 \text{ with H off.}$$

THE COST OF GENERATION AND DISTRIBUTION OF ELECTRICAL ENERGY.

The paper on the above subject, prepared by Mr. Hammond for the Institution of Electrical Engineers, and of which an abstract was read by him at the meeting on March 24th, is certainly one of the most valuable contributions of recent times, and should be specially appreciated by all those who desire to make themselves acquainted with the present position and future prospects of the supply industry on account of the great mass of statistics which has been collected and tabulated by the author.

In introducing his subject, Mr. Hammond explains how it is that the supply industry is obliged to furnish such detailed cost sheets, to prepare the annual statement of accounts in a prescribed form, and to publish and sell these statements to any applicant for not more than a shilling a copy. It certainly does seem remarkable that this obligation should have been accepted without a murmur when we know that no other trading concerns are under the same necessity, and that the majority of them would strongly object to publishing details of their costs of production; but it must not be forgotten that the conditions are somewhat special in that, with very few exceptions, there is no direct competition, and that a knowledge of the working costs of one concern can seldom be used to its detriment by a rival company anxious to engage in a war of cutting down prices. Whatever the reason may have been for the acceptance of this obligation, there is little doubt that the publication of these accounts has had a beneficial effect, and has fostered a healthy rivalry between managers and engineers of supply undertakings, each of whom has generally been anxious to go one better than his neighbour. There is a danger that this may be carried too far at the expense of the financial soundness of the undertaking, and that managers may have a tendency to charge certain items to capital account which more properly should be included in revenue account; but we believe that the Board of Trade is not by any means inclined to leave such matters entirely in the hands of the managers, and that this danger, if it exists, is therefore not an important one.

Attention is drawn to certain differences in the form of accounts prescribed for local authorities and for companies, and we quite agree with Mr. Hammond that it is desirable to procure uniformity as an aid to a useful comparison of the accounts of various undertakings. These differences are that the companies have to charge a proportion of the salaries of engineers to cost of generation and distribution, whereas the local authority charges the whole to management, and that provision is made in the companies' form for remuneration of directors and auditors and for depreciation. With regard to the salaries of engineers, it would certainly be more reasonable that the local authority should do as the company is obliged to do, and that in both cases a proportion of the salary of the managing engineer only should be charged to management; and as regards depreciation, a more uniform manner of dealing with this charge is desirable, although we do not see how this can be brought about by any change in the form of accounts.

Before dealing with what is the subject proper of the paper, viz., the cost of production, we would refer to one or or two points connected with the financial side of the matter, and to which reference is made by the author. Mr. Hammond almost apologises for going beyond the analysis of the works' costs, on the ground that it may be objected that anything else is outside the province of the engineer; but, although this is true to a certain degree, it is equally true that the extent to which electrical energy will be used does not depend only on the works' cost, but on the total cost, or rather on the price at which the unit can be sold. Although it is quite true that in any existing undertaking the engineer cannot exercise any control over the cost of management, and that he may have had nothing to do with the choice of the system and the design of the plant, so that he is in no way responsible for the amount of the annual charges on capital expended; yet, if anyone is desirous of arriving at a just comparison of two undertakings, it is impossible to leave out of consideration those sums which must be paid out or set aside annually in order that the undertaking may be worked on a sound financial basis. With the local authority there are annual charges which must be met for interest on and redemption of loans, and with companies there are dividends which, from the shareholders' point of view, it is absolutely necessary to pay; and these payments, the amount of which depends on the capital expenditure, must be paid out of revenue, and very materially affect the price at which the unit can be sold, and therefore the chance of success of the undertaking.

We all know that working costs can be kept down by the expenditure of large sums on economical engines and dynamos, on condensing plant, and on works for providing a supply of water for condensing so that water rates have not to be paid, on labour-saving appliances, and on the laying of very heavy copper mains to keep down the cost of distribution; but would it be fair to place such an undertaking in front of another whose working costs are somewhat higher, because it has been deemed advisable not to expend large sums on condensing plant, and on various appliances the use of which tend to reduce working costs, or because owing to local circumstances it has been decided to use smaller mains and transforming apparatus, without taking into account the difference in the capital expenditure of the two undertakings? Of course it may be that the expenditure in the first case is fully justified, and that the total cost of the unit, as we understand it, is lower than that in the second; but there are many cases in which this would not be so, and where the saving in capital charges would more than counterbalance the increased cost of working.

Another point which is discussed by Mr. Hammond is the amount which should be set aside for reserve or depreciation fund. Mr. Hammond agrees with the opinion held by many local authorities, that the obligation in their case to repay the loans to cover capital expenditure in about 25 years is sufficient for all purposes, and that it is not necessary to set aside anything for reserve under these conditions. We consider that those authorities are acting wisely who exercise the power given them by the Board of Trade to set aside annually a sum for depreciation until this reserve amounts to one-tenth of the aggregate capital expenditure; since, although their plant may be kept in good working order by the execution of repairs, yet it does not follow that all the plant will have a useful life of 25 years. For example, is it not probable that, before the 25 years have expired, some of the boilers may no longer be fit for use at the high pressures which are now generally employed? They may have been maintained in good condition, but it is a common thing to find that, after 10 to 12 years, the boiler insurance inspector insists on a reduction of working pressure, and in such a case, although the boiler may be perfectly serviceable for continued use at this reduced pressure, it is no longer suitable for the service required of it in the central station.

Again, it often happens that a station starts operations with generating units which are found to be too small after a few years working, and have to be taken out to make room for larger units; and it would be sounder finance to pay at any rate a proportion of the cost of this charge out of a depreciation fund, rather than to create fresh capital charges for the whole. We have, so far, spoken only of local authorities, but the same remarks apply to companies; and, indeed, these latter, in the great majority of cases, do not set aside as much as the 3 per cent., which is the average annual charge for the redemption fund of the local authority. Although it may not be advisable to handicap an undertaking in its earliest years by a heavy charge for depreciation, we think that as soon as it is possible to pay a dividend which will keep the value of the shares at par or a little over, it would be better finance to devote any surplus revenue in the first instance to building up a reserve fund, and that in considering the possible minimum gross cost of the unit when supplied by a well established company, a charge of something like 5 per cent. should be included for depreciation and reserve.

These general questions are of interest in considering an extract from our contemporary, the *Engineer*, which was quoted in the paper and commented on by Mr. Hammond. This extract, after stating that it is only under peculiar circumstances that the unit can be obtained at a less price than 5d., concludes by saying: "For about 20 years we have been told that its cost is to be reduced next year. The reduction has not come yet; and the worst of the matter is that all the large producing companies, who ought to know—and who are for the most part keenly competitive—tell us that they see no prospect of being able to reduce the price." Mr. Hammond justly takes exception to the first part of the paragraph we have quoted, and points out that both the cost of production and the selling price of the unit have been very largely reduced, since the first pioneer companies started operations less than 20 years ago. But on the question of the gross cost of production, or, rather, on the probable minimum selling price of the unit, Mr. Hammond says very little; and we think that our contemporary, as we ourselves should, would rather that Mr. Hammond should have dealt more fully with this part of the subject, and have given us his ideas of the probability of a general reduction of the price below 5d. per unit.

With a company much depends on what the directors consider a proper remuneration to their shareholders, but with a local authority, where there are no shareholders to consider, and where the charges for interest and redemption are fixed, it is possible to get some idea of the minimum selling price which would pay the works' costs and the charges for management, interest, redemption and depreciation. If we consider the balance-sheets for 1896 of five of the leading Coporations, Bradford, Brighton, Edinburgh, Glasgow and Manchester, we find that their aggregate capital expenditure at the end of the year was £965,000, and that they sold during that year 7,930,000 units, at an average price of 4·46d.; and further, that after paying the cost of production, including management, and the interest on their loans, they set aside £41,500 for depreciation and redemption fund, and still had a surplus of £29,500. The average cost per unit sold, including rent, rates, taxes, management, &c., was 1·62d., to which interest on loans added ·69d., and depreciation and redemption fund 1·26d., making a gross cost of 3·57d., which is therefore the average price at which the unit might have been sold if no surplus had been made. The amount set aside for depreciation and redemption fund varies considerably, Glasgow having set aside over 8 per cent., whilst Brighton's figure is little over 2½ per cent.; but if we allow a uniform charge of 2½ per cent. for interest, and 5 per cent. for depreciation and redemption fund taken on the capital expenditure at the end of the year, we find the gross cost per unit sold would have been 3·81d., so that we may confidently expect that, for important undertakings, local authorities will be able to supply at an average price of 4d., and that at that price the undertakings will be on a thoroughly sound financial footing, and will have a margin to spare after the payment of all charges.

SOME NOTES ON SINGLE-PHASE MOTORS.

By A. C. EBORALL.

(*Continued from page 356.*)

The curves given in figs. 14 and 15 are typical of the excellent single-phasers made by this firm. Fig. 14 gives the efficiency, power factor, and speed regulation of a 110-

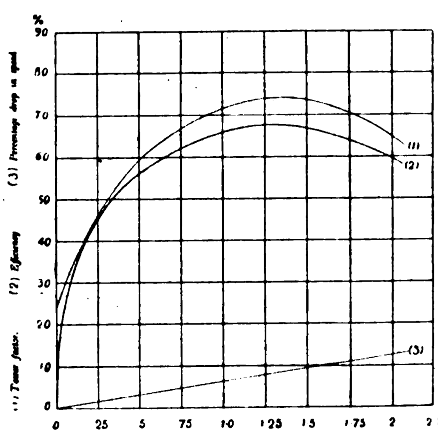

Fig. 14.

volt, 40 ~, 1½ H.P. motor fitted with simple short-circuited bar armature. It will be seen that the power factor and efficiency are both high over a considerable range, and the speed regulation is also very good, especially when the small size of the motor is taken into account.

Fig. 15 shows the same thing for a six-pole motor designed to give out 3 H.P. at 100 volts and 100 ~. It had a wound

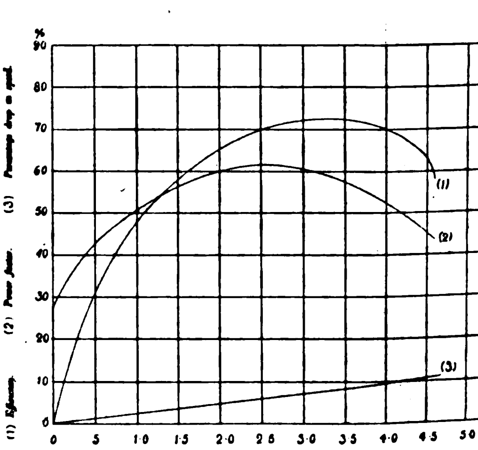

Fig. 15.

rotor arranged for a starting resistance. The efficiency is very high, but the power factor not quite so good as in the last case, owing to the greater number of poles. The starting torque was equal to the full load torque when the starting current was allowed to be about twice the full load current.

Fig. 16 concludes this account of the Brown single-phasers. It is a 70 H.P. motor, working on the Frankfort 45 ~ 2,800-volt lighting mains, and runs at 540 revolutions per minute. The starting arrangements have already been shown in fig. 12B.

(*B*) *The Oerlikon Company.*—This is another company who were early in the field with single-phasers. Their constructions do not call for special notice, as they are very similar to those of the last firm. Their starting device is, however, somewhat different, owing to the fact that a choking coil is used instead of a condenser. The motor being wound with two windings, a choking coil is put in series with the one of greater self-induction, which is generally the starting winding with many turns, and a non-inductive resistance in series with the working winding. The two are put in parallel across the mains, when the difference of phase produced is large enough to start the motor up on a loose pulley. Sometimes the non-inductive resistance is left out—and a rotor resistance is always used for the larger units. This starting device requires more current than the previous ones described, and, generally speaking, is not so effective.

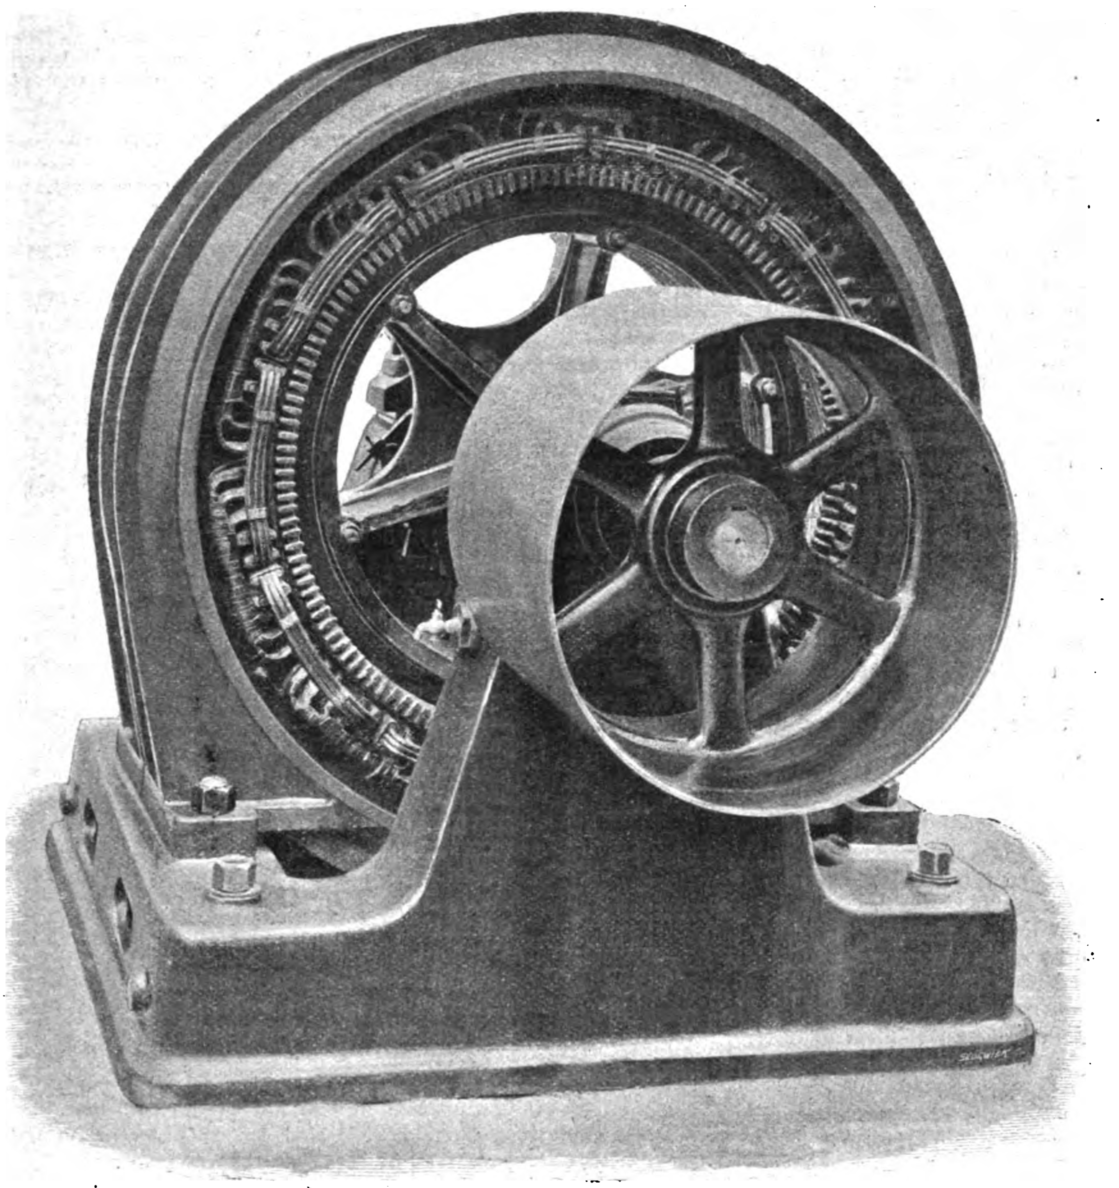

Fig 16.

(*C*) *Messrs. Kolben & Co.*—This firm is the latest making a speciality of alternate current plant, and especially of induction motors. Their single-phase motors show in their design that attention to detail which would be expected from Mr. Kolben's large experience with this class of work. The accompanying table gives some interesting information in regard to the low tension motors for 50 ~ circuits made by his firm.

CORRESPONDENCE.

The Burning Question.

The interesting communication of your correspondent, A. J. Liversedge, again prompts me to trouble you with a few lines upon the above subject, and to join with him in expressing personally my thanks for the opportunity you have given for full and free discussion in your valuable paper, the ELECTRICAL REVIEW, and it is at the present moment that we are particularly grateful, for although much has been "utterly erroneous," the time is evidently rapidly approaching when "Eureka" will be your proud motto blazing forth above the portal of your office in all the beauty given by 10,000 incandescent lamps, the outcome of the now all-powerful compound "pressed sludge and house refuse." That I am right in this conclusion I feel quite sure. Mr. Liversedge virtually says that "Now we shan't be long," and I will not attempt for one moment to go behind the happy conclusions at which he has arrived; at the same time it would be more satisfactory when figures are quoted as to the cost of burning, that it should be clearly stated whether or no the capital charge, principal and interest has been taken into account. There are so many items to be fairly dealt with, that I need not make any apology for the suggestion. Mr. Liversedge's reference to a previous correspondent whose "imagination" went somewhat astray with respect to what takes place at Ealing is very much to the point. I did not reply to the said previous correspondent, time I felt was "too precious." I may, however, now add to previous information that one-third of the house refuse is used in the drainage of the sludge, the remaining two-thirds is tipped on the destructor in the ordinary way and all burned together; the drainage goes on usually for seven days. One thing is certain, that although I have tried again and again the burning of *pressed* sludge, I have never succeeded in obtaining as a result a good hard and useful clinker such as I obtain from the compound produced at Ealing.

Mr. Liversedge has referred to a communication I made some years ago to the old Metropolitan Board upon this question, and in looking over my papers I turned up one of my lectures 1890 which deals with this very point. In eight years necessarily there have been change and improvement, but the general remarks will apply almost as well to-day as when they were written, and as it may interest some of our readers, the following extract gives the principal points:—

I have spoken and written upon this subject of house refuse and sludge burning for some years past, and I called the attention of the Metropolitan Board to the matter, but without effect. Although they did carry out some experiments, they were carried out in such a way that it was impossible for them to succeed, so little did their officials know about it. At the discussion at the Institute of Civil Engineers upon Mr. Dibden's paper upon "Sewage Sludge," Mr. Dibden said: "Mr. Jones did not contend that he could burn the unpressed sludge, but only the pressed, and based upon that an enormous annual outlay for the purpose of pressing. But the real fact of it is, gentlemen, I have never pressed a ton of sludge since my destructor has been in work, but it is mixed with house refuse, goes into the furnace in almost a semi-liquid state, and is delivered as a hard and valuable clinker. Mr. Dibden stated that before the pressed sludge can be burned the water must come out by heat, but he concluded with these significant words, that if dust-bin refuse of a town is available, doubtless the object can be attained by the use of destructors." In these few words I maintain that you have the solution to the difficulty. Why should not the Metropolitan Board of Works have had the refuse of the dust-bin? The various authorities along the banks of the Thames would have been only too glad to have had a depôt, and barge it down to the northern or southern outfall. We all know the trouble that for years and years has gathered round this question, when a remedy so readily might have been found. I have been told that the quantities are so large, and the amount of sewage is so great; but it seems strange in these days of the Forth Bridge to hear words of this class. The whole treatment of the London sewage at two outfalls would be a mere bagatelle, if those with whom the matter rests would face the difficulty. I have stated that in England at the present time there are some 200 cells at work employing less than 100 men, and dealing with something like 500,000 tons of refuse. How much room do you think these 200 cells would take, supposing they had been built at Barking, where, I believe, there are some 70 acres of land available? You will be surprised to hear that they can be put upon an acre of land, with plenty of room to work between them, and that the cost of erecting them would not amount to more than £300 or £350 per cell. Supposing the 200 cells had been built, and the question tried, there would have been, according to the data which we have, and which there is no disputing as it is in daily work, 1,000 H.P. at hand, or in other words, the coal bill would have been saved. No nuisance would have been created by the adoption of the process, which after all that has been said with respect to other systems, has held its ground, and will do so still. I refer to the milk of lime process, which will ultimately come about. I know that it may be replied that the effluent that is turned out by this process is not pure. No one in the present day would say that it was, but the question is, is it not pure enough to be discharged into the Thames at Barking and Crossness? I have been sending, to the satisfaction of the Thames Conservators, from 750,000 to 1,000,000 gallons of effluent per day for many years into the Thames, and many visitors have made the remark, and not a few of them members of the Metropolitan Board of Works, why cannot we do the same, and I say unhesitatingly, that under the lime process and the destruction of refuse, as suggested by me, the river would assume a character in every way satisfactory, and at a mere bagatelle of cost when compared with the expensive schemes already referred to. Other points might be raised in connection with this effluent water, for instance, that of aeration. And here I may add that sufficient steam would be produced from the refuse, over and above the quantity required for ordinary pumping purposes, which might be brought to bear upon the effluent in aeration, and which, to my knowledge, can be productive of immensely beneficial results.

Charles Jones, M.Inst.C.E.

Ealing, *March*, 1898.

Electric Power Supply from Central Stations.

I am obliged by the length at which you have reviewed my little paper on "Electric Power Supply from Central Stations." The paper was read at short notice before a body of men who are not specialists in electricity; it was also desired that it should not take more than an hour in delivery including the exhibition of some 30 lantern slides. Further, it is to be remembered that the proposals of the Midland Electric Corporation are still *sub judice*, and that until it is settled over what areas they will have powers it is very difficult to speak exactly from an engineering point of view. For all these reasons then the paper was qualitative in character and tone, rather than quantitative.

As regards your suggestion that more actual figures as to the capital cost of water power installations should have been given, it would have been beside the purpose of the paper to have treated this part of the subject in greater detail. In the discussion, however, which followed, the president, Mr. J. W. Hall, gave some actual figures entirely confirmatory of my general conclusions, of which I enclose a copy.

Coming now to your criticism that in estimating the relative cost of coal and stoking for a plant running continuously, as compared with a plant working 54 hours per week, I had not made sufficient allowance for "Power Factor."

Allow me on this point to refer to a paper on the "Electric Transmission of Power," read on December 8th, 1894, before the North of England Institute of Mining and Mechanical Engineers, by Mr. Alexander Siemens.

On page 5 the paper reads as follows:—

"As far as they go these comparisons prove that the electric transmission has been economical, but in order to obtain satisfactory information as to the performance of the plant, a series of tests were conducted by the experimental department under the direction of Dr. Eugene Obach, as follows:—

"The boiler tests and the engine tests were carried out separately in two series. The first series was intended to determine the weight of steam generated per pound of fuel, and this test extended over a month of ordinary working, and included all necessary coal for lighting up. The second test series was intended to determine the weight of steam required by the engines, per Board of Trade unit delivered to the distributing bars of the central station switchboard. This was found by exhausting the engine under test into the main condenser, and measuring the overflow from the air pump, taking care that no other could mix with overflow.

"These engine tests were subdivided again into two kinds: —(1) Running on steady artificial loads of about one-quarter, one-half, three-quarters and full load, and (2) running on the ordinary day load.

"*The second set of tests was undertaken to see if a varying day load required the same weight of steam per Board of Trade unit as a perfectly steady artificial load giving the same output. This was found to be the case, the point obtained by the day load test fell exactly on the curve obtained on the steady load tests.*" (Fig. 6, Plate 15.)

In a central station with a number of engines, those working would always be near their economical load, and boilers give a high efficiency when worked at low rates of evaporation.

In the case of the Midland Electric Corporation there is every reason to anticipate that with good management a better load factor than 54 hours per week will be secured, even without the use of accumulators.

I now come to your remarks on the rates it is proposed to charge for power by the Midland Electric Corporation.

As a matter of fact there is nothing in my paper as to the rates at which the Midland Electric Corporation actually propose to supply power. What I did say is as follows:—"In their agreements with the local authorities, who have so far come to terms with the Midland Electric Corporation, the following are the rates for power supply, which are not to be exceeded: 3d. per unit for first hour's use per diem, taken on the maximum demand in any quarter, the number of first hours being taken as 78, *i.e.*, 6 days per week for 13 weeks, ·825 of a penny for each subsequent hour's use."

I did not say that these are the terms on which the Midland Electric Corporation have determined to supply, *but these are the terms which they have agreed not to exceed.*

In electric lighting orders it has been usual to specify that the maximum charge for supply shall not exceed 8d. per unit. It does not necessarily follow from this that the company or authority will charge the full maximum even to start with, nor that they will charge large and good customers the same rate as the small ones.

The actual rates for power supply I must leave to the future, all I will remark is, that there is no reason to doubt that as time goes on, power supply undertakers will be able to make as great a reduction in their initial maximum rates as electric light undertakers have been able to make on the maximum rates of electric supply for lighting during the last 10 years.

Further, coming to your comparison of the cost of power generated by an isolated plant with the rates per annum the Midland Electric Corporation would charge under similar conditions, I am pleased to see that you acknowledge that even on the assumptions you make, for any power up to 50 kws., it would be advantageous to take supply from the Midland Electric Corporation, the user securing all the advantages of electric working into the bargain.

A 50-kw. plant needs an engine of at least 80 I.H.P to drive it, and as there is usually some saving in power in employing electricity, you appear to agree that there would be advantages in replacing every engine in the district working under the conditions you mention as ordinary ones, up to 100 I.H.P., the advantages increasing very rapidly as the sizes got smaller.

Now 100 I.H.P. is a considerable size for the engine of ordinary engineering and manufacturing works, excluding rolling mills, textile factories, and some other industries; such an engine implies a factory employing approximately 150 to 200 men under present conditions.

But your comparison even on this basis does not include anything for spare boilers or plant, either mechanical or electrical, in the case of the isolated plant—a most important consideration to a manufacturer; while by taking power from the central station he would have nearly the security of duplicate plant. Lastly, you assume that the maximum load to be met with will be double the average load, which, as a general statement, is no doubt accurate. The deduction which you make from this, however, that it is proposed to take full advantage of this fact in supplying current from the central station on the demand meter system, is not correct.

It is one of the great advantages of centralisation that the wider the range of supply the less are sudden local increments of power felt, and it has always been the desire and policy of the directors of the Midland Electric Corporation to give manufacturers, as far as reasonably could be done, the benefit of this.

While, consequently, they have decided to supply electric power on the demand meter system, it is not their intention to do so with the aid of recording wattmeters or ammeters. What they do propose is to use something of the character of Mr. Wright's instrument, which takes some time to reach a maximum reading.

In this way the maximum demand will not bear an undue proportion to the average, so that the average cost of power to manufacturers will be less than you assume, even taking the full rates which the Midland Electric Corporation have undertaken not to exceed.

Although it is not alluded to in the paper, the Midland Electric Corporation proposals also include the provision of electric lighting over a large district at cheaper rates than the authorities could do it for themselves, even if they cared to embark in the necessary capital expenditure.

While, therefore, your conclusions are generally favourable to the Midland Electric Corporation's enterprise, I think you will agree, after this explanation, that their proposals, if the local authorities allow them to be carried out, will be considerably more advantageous than your leading article indicates.

Remember, also, that this is what prudent men, after carefully weighing the circumstances, feel that they can do to start with, and it is always the beginning that is the difficulty.

I am sorry to have written you at such length, but in justice to the directors who have spent much time on the undertaking, and especially the chairman, Mr. J. F. Albright, it is important that there should be as little misunderstanding of their proposals as is compatible with the inauguration of a new enterprise, and one which to a considerable extent breaks fresh ground.

G. L. Addenbrooke.

The Association of Electricity with Atmospheric Phenomena.

Your correspondent, "Delta," will perhaps be interested to hear that early on Tuesday, the 15th inst., a similar phenomena to that of the Aurora Borealis was seen from Blackpool and Thirsk and at other northern towns; and about the same time and day a *water-spout* was seen from the coast of the Isle of Man. This is a remarkable coincidence, and points to an electrical association. Perhaps some of your readers could say whether there were any striking barometrical changes on the date named in the places mentioned.

Magnet.

LEGAL.

Leicester Corporation *v.* Warren Hill.

Important Judgment.

At the Leicester County Court on Friday, his Honour Judge Wightman Wood delivered judgment in the case of the Leicester Corporation *v.* Warren Hill, electrician, King Street, Leicester.

His Honour said the case, which was heard last month, was one of unusual importance to come before a court of limited jurisdiction. The action was in respect to the price of lamps and other fittings used in connection with electric lighting, sold and delivered to the defendant, who, whilst admitting the purchase, said that it was *ultra vires* of the Corporation to trade in such articles, and that they could not maintain an action for the price. He (the Judge) further understood that the claim was resisted in order to test the right of the Corporation to deal in such things. Under the Electric Lighting Act of 1882, the Corporation were licensed by the Board of Trade to supply electricity for public and private purposes, and besides laying wires, erecting the necessary machinery, and supplying the electric energy to such householders as liked to have it, they had also opened an emporium—he supposed they did not term it a shop—for the sale of lamps and such other fittings as were required in houses by persons who made use of the electric light. No attempt was made to confine the sale to householders who took the electricity, nor was the defendant such a person. He was an engineer with a similar business of his own, and the articles which he purchased from the Corporation he added to his stock. All the facts were admitted, and the matter in dispute was entirely a question of law. A corporate body could only do such things as it was authorised to do by charter, Act of Parliament, or means of association which brought it into being, or supplementary Acts or charters, including all such things as were necessarily incidental to the expressly authorised objects. All other things it was prohibited from doing. The plaintiffs' charter was not produced, and it was conceded by their advocate that no right to trade could be deducted therefrom, and he relied entirely on recent electric lighting legislation. Having reviewed the various sections of the Acts of 1882, 1888, and 1890, his Honour said he could see nothing by reasonable implication to authorise the Corporation to supply any material fittings except meters. The Corporation advocate, however, had placed great reliance on a form of account sent down by the Board of Trade, and it certainly appeared from that form that the person who drew it up contemplated that the Corporation would buy and sell lamps and other apparatus, and it might be that the Corporation had taken their cue from it, and had taken to trading in lamps on the strength of its wording. He was, however, of opinion that a mere indication by a Government department that in its judgment a thing may be properly done, could not have the effect of authorising that which would otherwise be contrary to law. Section 9 gave the Board of Trade no authority to authorise anything at all, but merely to prescribe the form in which the Corporation were to present their accounts "of the undertaking" authorised by the Act—that was, the duty of supplying electric energy. *He was therefore of the opinion that the contention of the defendant that the Corporation had acted beyond their legal powers in selling the articles in question was correct.* Defendant, however, having taken and kept the goods under an implied promise to pay, the question arose, "Could he now set up as a defence to an action for the price that it was *ultra vires* of the Corporation to sell?" In his (the Judge's) opinion he could not, for the defendant having had the goods, could not be allowed to refuse to pay for them on the ground that the Corporation went beyond their legal right in selling them, and could not have been held to their contract to deliver them had they refused to do so. The defendant had got what he bargained for and he must pay the price, notwithstanding the flaw which he had rightly called attention to in the capacity of the Corporation to carry on their business. As he was against the plaintiffs on the point on which they relied, and which the parties came there to contest, he would give no costs, and judgment would therefore be entered for the plaintiffs for £4 19s. without costs, with leave to appeal.

VAUGHAN & BROWN *v.* TERRY.

AT the Clerkenwell County Court on Friday last, plaintiffs, electrical engineers, of Kirby Street, Hatton Garden, sued Mr. Edward Terry for £9 14s. 8d. for work done in connection with Terry's Theatre. For plaintiffs it was stated that the order had been given by Mr. Brickwell, Mr. Terry's business manager, and Mr. Brickwell gave evidence that he had acted in that capacity in giving the order to plaintiffs. Mr. Terry gave evidence that Mr. Brickwell was, at the time this contract was given, temporarily acting for Mr. Carr at 15 guineas a week. He never authorised Mr. Brickwell to carry out the work claimed for. The deputy-judge (Mr. Horton Smith) found for the defendant, with costs.

BUCK & HICKMAN *v.* BINKO & CO.

THE plaintiffs in this action, a firm of tool manufacturers, sued Mr. Henry Binko, electrical engineer, of 34, Leadenhall Street, at the Lord Mayor's Court, before the Recorder, to recover the sum of £16 2s. 4d. in respect of goods sold and delivered. The defendants pleaded that the whole amount was tendered before the action was brought, and the sole question was as to whether there had been a proper tender. Mr. Henry Binko stated that in January last he received an application from Messrs. McKenna & Co. for an amount of £16 2s 4d. due to plaintiffs. There was a dispute at the time between him and plaintiffs over a sum of 4s. 5d. Witness drew a cheque for £15 17s. 11d., and subsequently, after his attention had been called to two credit notes for the 4s. 5d, he added another 4s. 5d. That amount was taken on to plaintiffs, but was refused on the ground that the matter was out of their hands. The plaintiffs contended that the amount tendered to them was £15 odd, and as that was not the full amount, they refused to accept it. Eventually the jury found for the plaintiffs for the amount claimed.

WILSON *v.* ELLIS.

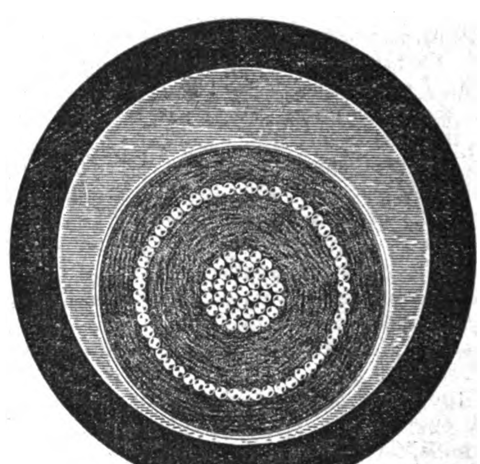
THIS was a claim by a traveller for £28 odd for commission for orders for electrical work obtained for the defendant, who has an office in the district of the Westminster County Court, and a branch at Croydon. Plaintiff, it seemed, obtained an order from the builders who were reconstructing the "Old George," Croydon, to do the wiring, and for that he was entitled, with other jobs, to £11 commission. Subsequently, through his introduction, defendant obtained the order for fittings. Defendant's case was that the order for the fittings came through another servant of their's and that plaintiff knew nothing of the order for fittings until after it had been obtained. They had paid the other amounts into Court, but this £18 they did not think he was entitled to. His Honour, in giving judgment for the plaintiff, said the introduction came through him, and but for that defendant would not have obtained any order at all.

BUSINESS NOTICES, &c

American Competition in Europe.—Mr. F. H. Mason, United States Consul-General at Frankfort, has, says the *Times*, given some interesting information on the subject of American competition in Europe in his annual report to his Government. He states that 1897 will be remembered as an epoch in the industrial and commercial relations between the leading European countries and the United States. The remarkable fact of the year has been the enforced recognition of the truth that in several important lines of manufacture—notably that of iron and steel—the sceptre of economical production, combined with the payment of the highest wages to labour, has passed from the old world to the new. It has been demonstrated that, under intelligent, progressive management, highly paid labour, especially when employed to use complicated machinery, is, after all, the cheapest, and that in the race for supremacy the people of the old world have been in many cases left behind by those who, more than any other, have reduced economy of labour to an exact science. It is now seen that it is something besides the tariff that has made the cost of producing Bessemer pig iron from 10s. to 15s. per ton less in the United States than Great Britain, has enabled the steel-makers of Pennsylvania to underbid those of England for the rails and other supplies of the London underground railway, and to place an order for 8,000 tons of steel rails with the Indian Government. Neither has fiscal legislation enabled the machinists of Philadelphia, Pittsburg, and Chicago to sell locomotives, mining and electrical machinery, tramway outfits, bridges, and architectural iron in competition with British, German, and Belgian agents in South America, Australia, and the Cape of Good Hope. The leading makers of electrical machinery in the United States have set a standard of cheapness, prompt delivery, efficiency, and economy of service, especially in electrical railway plant, with which their European rivals find it difficult to compete.

Birmingham Electrical Exhibition.—The installation for lighting the buildings of this exhibition at Bingley Hall was put down by the Walsall Electrical Company. Messrs. Henry Sassons and Co. have an effective display of fittings, and there are exhibits by a large number of electrical firms. There are to be wireless telegraphy, and X ray demonstrations.

Brook's Semi-solid System of Insulation.—Messrs. Johnson & Phillips have issued a pamphlet on the above system. We understand they have had experience of these cables for the past eight years, and are convinced that they are an advance in the right direction as regards the transmission of electrical energy. No faults have occurred on the lines laid; but, on the other hand, the insulation measured in megohms, and, what is of more importance, the insulation as regards dielectric stress, is in all cases higher to-day than when originally laid. We illustrate a full size section of the ·15 square inch high tension concentric cable supplied for the Corporation of Worcester, which has relied for some years on two Brook's mains for connecting the city with the generating station some three miles in the country. The pamphlet before us describes



the Brook's system in detail, together with the method of laying and jointing. In this system the copper conductors are closely and thickly covered with two helical bindings of strong fibrous material impregnated with a highly insulating compound. The cables are drawn into thick iron tubes, which are afterwards filled with a highly insulating semi-solid dielectric and hermetically sealed. The cables are thus completely protected from all deteriorating influences. It is claimed that with the use of this type of underground cable there is a great factor of safety against faults, an absence of material exposed to any action likely to deteriorate it, and by its use one has an insulation as reliable and permanent as is possible.

Catalogue.—Messrs. Binko, Ridsdale & Co., Limited, of Leadenhall Street, and Minories, have issued a 290-page catalogue, bound in red cloth covers, in which they describe, illustrate, and give prices of the great variety of electrical apparatus and accessories, in which they trade. Department I. covers electric signals, electric telegraphs, telephones, electric bells, fire alarms, lightning conductors, and medical appliances. Section II. is devoted mainly to electric lighting, and describes accumulators and fittings for ships and domestic use, dynamos, and motors, &c. The book will be of service to the firm's customers, and the electrical trade generally.

Crompton & Co., Limited.—The petition presented to the Courts for confirming a special resolution reducing the capital of this company from £280,000 to £162,000, will be heard by Mr. Justice Wright in the Chancery Division, on April 6th. Anyone desiring to oppose the proposal should then appear.

Dissolution of Partnership.—Messrs. A. Harrison and E. C. Pringle (trading as Harrison, Coles & Co., electrical engineers, Hermitage Works, Richmond, and Kensington) have dissolved partnership.

Electrical Installation at the Thames Ironworks.—The Institution of Junior Engineers will to-morrow (Saturday) morning pay a visit to the Thames Ironworks and Shipbuilding Company's works at Blackwall. The following notes on the electrical engineering department are of interest. The central generating station has been established in the works near the shipyard gate. The installation consists of three locomotive and two "Gunboat" boilers —the latter of the company's manufacture—aggregating 600 I.H.P.; engines and dynamos aggregating 360 I.H.P., three of them built by the company. Distribution of current is effected by three-wire system, the main cables to distributing centres being of vulcanised India-rubber insulation, laid in cast-iron pipes underground. The electric current generated is chiefly used for lighting purposes, but several examples exist in the works of the use of electromotors, and the use of electricity for power purposes is in course of extension. Electric drilling machines are a speciality. Several types of these machines are found on H.M.S. *Albion*, in shops of the shipbuilding department, and in various parts of the yard. Others are under construction in the upper machine shop of the engineering department. Dynamo and motor construction is carried on as a branch of the engineering department (upper shop). Electro-galvanising of boiler tubes, plates, &c., is seen near ss. *Diogenes* and alongside boatbuilding sheds. Current for plating is obtained by transformation from the electric lighting mains.

Elmore Director's Fees.—At the Leeds Assizes on Saturday last, Mr. Justice Ridley gave judgment for the plaintiff in the case in which Mr. J. North, solicitor, of Leeds, sued the Elmore's Patent Copper Depositing Company, of London and Leeds, for £600, as director's fees. For the defence it was argued that directors' fees had been held to be a gratuity and could not be sued for. His Lordship, however, ruled against this point.

Fires.—On Saturday last a fire occurred on the premises of Messrs. Downie & Adams, electrical engineers, Newman Street, Oxford Street, W. The fire originated in the showroom of Messrs. Wenham & Waters, and Messrs. Downie & Adams ask us to state that their business has not been in any way interfered with by the occurrence.

On Saturday last a fire occurred on the premises of Messrs. C. and G. A. Parson, electricians, George Street, Bath, and did considerable damage.

On Thursday night last week, a fire occurred on the premises of Messrs. Hamer & Co., electricians, in Herton Street, Halifax. The building is a three-storeyed block.

Electric Light Fittings.—Messrs. H. M. Salmony & Co., of Charing Cross Road, have brought out a new catalogue. The copy before us is an *edition de luxe* of about 400 pages, including section P.A., describing electric light plant and accessories; section F.G. dealing with electric light fittings and glassware; and section H.C.

Fig. 1.

particularising electric heating and cooking apparatus. We can only afford space for brief mention of the great variety of machinery and apparatus which is well illustrated and clearly printed in this volume. Section P.A. deals with dynamos, motors, combined plants (gas, oil

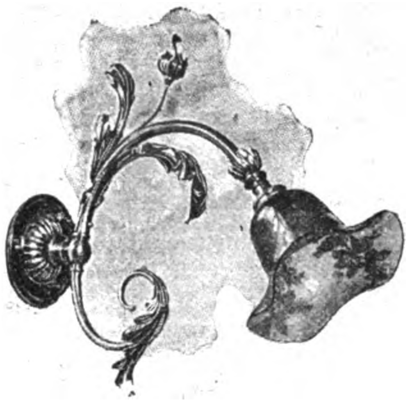

Fig. 2.

and steam), turbines, accumulators, arc lamps, switches, cut-outs, measuring instruments, &c. The electric light fittings section embodies a really excellent selection of artistic fittings, such as brackets, standards, electroliers, ceiling fittings, &c. For neatness of

Fig. 3.

design and general arrangement they compare very favourably with anything of the kind that we have seen. We select a few of the specimens for illustration. Fig. 1 shows a three-light pendant in brown or grey bronze, with spray for the lamps. In fig. 2 is shown a bracket made in either polished brass, dead gold or wrought iron. A high-class ceiling fitting with hand-wrought leaf work is shown in fig. 3, with three lights. This is made in polished brass or copper. Fig. 4 shows a six-light electrolier, made either in polished brass or dead gold, with cast brass leafwork and ornaments, and cutglass

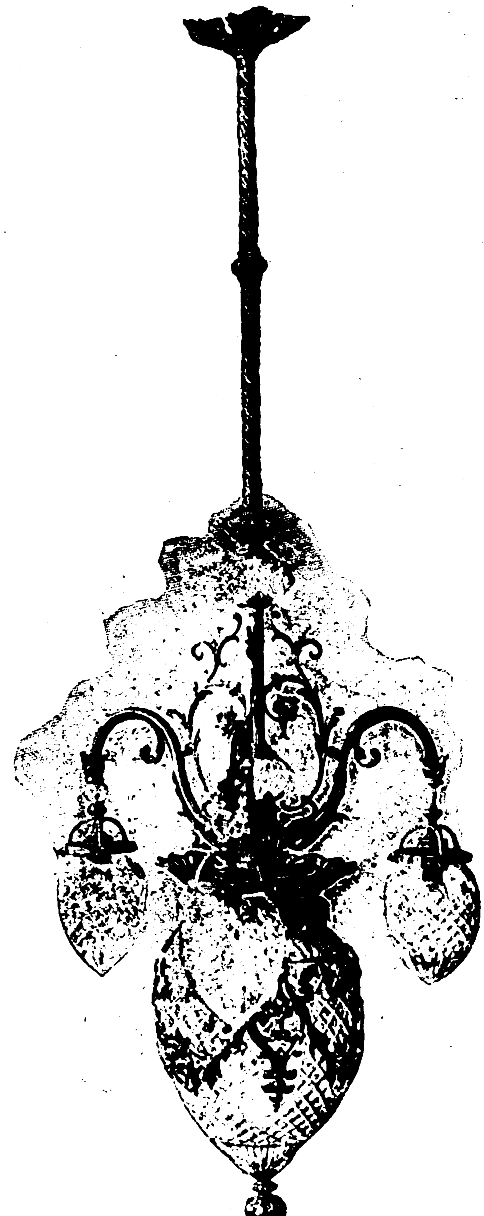

Fig. 4.

shades. These are only a few specimens selected off hand from the catalogue, but at the very complete showrooms in Charing Cross Road a great variety of excellent fittings can be seen to greater advantage than in illustrations. To facilitate the visits of contractor's customers to the showrooms a sheet of perforated introduction cards is given with each catalogue.

Holophane, Limited, v. the Stewart Electrical Syndicate.—In the Chancery Division on Friday last, before Mr. Justice North, Mr. Eady, Q.C., mentioned a motion in this case for an injunction to restrain the infringement of patents and passing off. Counsel stated that the motion was adjourned from last week, and since then an arrangement had been arrived at whereby the defendants had agreed not to dispute validity, and to submit to a perpetual injunction with inquiry as to damages and costs.

Lists.—Mr. J. D. Sutcliffe (of Sutcliffe, Statham and Co., Fennell Street, Manchester), sends us a copy of a paper read by him before the Manchester Society of Architects, on "Combined Warming and Ventilation of Public Buildings."

Mr. A. W. Roy, of Heaton, Newcastle-on-Tyne, has issued a March, 1898, list of his small dynamos and motors, and materials for same.

Receiving Order.—Messrs. James Fletcher and J. A. Hirst (trading as Fletcher, Hirst & Co., electrical and mechanical engineers, Bankfield Works, Curzon Street, Burnley, and lately at Chester and Derby) filed a petition for receiving order in bankruptcy on March 24th.

To Creditors.—Creditors of Bennett & Druce, lately trading as electrical engineers, at 30, Winckley Square, Preston, Lancashire, who have not already sent in their claims to Mr. J. Todd, receiver and manager, must do so by April 8th, after which date distribution of assets will be proceeded with.

Micrometers.—We have received from Mr. Robert Mühle, of Glashütte, i/S Germany, particulars of three forms of micrometer which he is manufacturing for the use of electrical engineers. For these is claimed the extreme accuracy rendered necessary by the delicate distinctions of diameter and thickness brought into use in modern electrical practice. Fig. 1 shows (half natural size) the

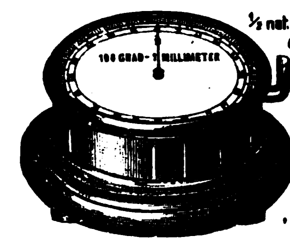

Fig. 1.

standard form of micrometer measuring by $\frac{1}{100}$th mm. This is made either in brass or nickel, the jaws project and are opened by means of a lever to admit the subject for measurement. An arrangement of spring, levers and gear actuates the pointer and shows the actual measurement on an easily read scale. The knife edges of the jaws are finely polished and are made with jewelled points if required, for measuring incandescent lamp filaments, screws, plates, wire, &c. These instruments are also made to read in $\frac{1}{200}$th, $\frac{1}{400}$th, and $\frac{1}{500}$th mm., and are guaranteed not to vary even with constant use. Fig. 2 is

Fig. 2.

another form with extended scale to show extremely fine divisions from $\frac{1}{100}$th mm. to $\frac{1}{3000}$th mm. The opening in this instrument is much larger. In the three sizes made the jaws open 12 mm., 40 mm. and 50 mm., and the largest size can be used up to even 75 mm. The illustration is half natural size. Fig. 3 is a convenient form for

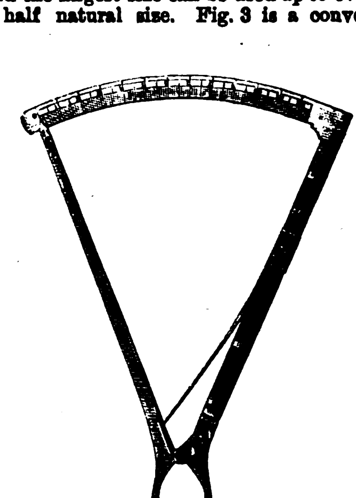

Fig. 3.

workshop use when extreme accuracy is not required, the readings being $\frac{1}{10}$th, $\frac{1}{20}$th and $\frac{1}{50}$th mm. The scale is isometric, thus avoiding circle errors. The adjustment is easy and the instrument is strongly constructed to stand ordinary workshop use. The firm of Robert Mühle was established in 1869, and has devoted a vast amount of attention to the perfecting of measuring instruments, of which the types we describe are good examples.

New Patent Friction Clutch.—The friction clutch illustrated below has been designed by the Unbreakable Pulley and Mill Gearing Company, Limited, of Manchester, to overcome some of the many difficulties attendant upon this apparently simple, but really very exacting class of mechanism. With regard to the clutch proper, it is not greatly different in the main design from some others in the market. The driving power is transmitted by heavy arms or horns, on which the friction blocks slide, so that all strain, except that of putting the blocks into gear, is taken from the screws. These are two in number, right and left handed, and the arm for their rotation is forged solid. The main and lock nuts are gun metal, to avoid any chance of rusting, should the clutch remain for long either in or out of gear. The patented novelty lies in the method of the application of the power from the usual sliding sleeve upon the shaft to the extremities of the screw levers. Instead of the connecting links

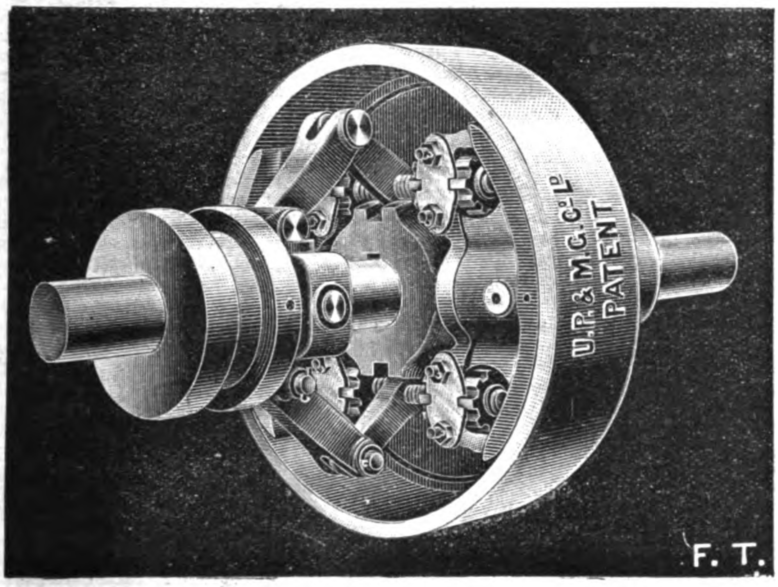

Fig. 1.

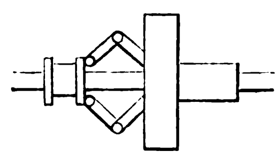

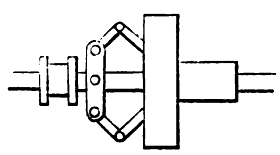

Fig. 2.

being carried in rigid centres on the sleeve, as is usually the case (fig. 1), they are pinned to a gimbal or ring, pivoted on the sleeve (fig. 2). It will be seen that, by this arrangement, any pressure put upon the sleeve must be transmitted with absolute equality to the two friction blocks, as either one of these gives the reaction for the other. Any chance of uneven wear on the blocks, or undue strain upon one part of the mechanism is thus avoided. We understand that a number of these new clutches have been sent out, and have been at work for considerable periods. Many repeat orders are stated to have been received. The clutch is made in various sizes, according to diameter of shaft and power to be transmitted, and may be used either to couple shafts or to carry a pulley. Adjustment is provided for in all ways, and all the parts, although guarded by the outer shell, are in full view, and at once accessible.

Paterson & Cooper.—Discharge Granted.—The case of Paterson & Cooper, electrical engineers and contractors, of the European Works, Pownall Road, Dalston, and Victoria Street, Westminster, with branches at Manchester, Glasgow and Dundee, reached the final stage this week at the London Bankruptcy Court, when Mr. Registrar Brougham granted an unconditional order of discharge to both debtors. The firm failed in August, 1896, with total liabilities £19,514, and assets valued at sufficient to pay the debts and leave a margin of £7,021. The debtors started business in 1882, with a capital of £18,000, and a further £6,600 was afterwards provided. In 1886 they purchased from the inventor, M. Eugene Hermite, a half share in the British and foreign patents of an electrical sanitation and bleaching process. Since then they have been almost continuously engaged in exploiting and working the patents, and have, in one way and another, expended from £12,000 to £13,000 in connection therewith. In 1886 the British patents were sold to a limited company, which proved unsuccessful and entailed a loss of about £5,000 to the debtors. Four years later the French patents were sold to a French company, and the debtors eventually realised £1,800 by the sale of their shares, received in payment of their interest in those patents. For some years before the failure the debtors were endeavouring to form a company to take over the patents, plant, and business of the French company. They attributed their failure entirely to delay in realising their patents. When the discharge was first applied for in January 1897, the Official Receiver reported as an offence that the assets were not equal in value to 10s. in the £ on the unsecured debts. That finding was challenged on behalf of the debtors, and the hearing has since been adjourned from time to time to enable the assets to be realised. Mr. E. Moore, the trustee, now stated that he was satisfied that the assets would realise in the gross sufficient to show 10s. in the £ on the liabilities. The Official Receiver offered, in that case, to withdraw the allegation, and said he would not oppose the granting of the discharge. His Honour remarked that as the only reported offence had now been displaced, he was enabled to grant to the debtors an unconditional order of discharge.

The Stratton Separator.—Mr. C. R. Heap, of 47, Victoria Street, S.W., who is the sole importer in the United Kingdom for the Goubert Manufacturing Company, of New York, sends us a pamphlet, emphasising the necessity of employing dry steam in order to obtain the maximum of economy, efficiency and safety, giving an exposition of the various methods of obtaining it, and describing good points of the Stratton system of mechanical separation. A page illustration is given of a 10-inch Stratton combined separator and steam receiver, connected to 1,200 H.P. compound Westinghouse engines at the power house of the United Electric Light and Power Company in New York City. Other illustrations show separators used by the Philadelphia Traction Company, and the Springfield Street Railway Company. There is a list covering many pages, giving particulars of firms and works in America employing the Stratton separator.

ELECTRIC LIGHTING NOTES.

Aberdeen.—Last week the Gas and Electric Lighting Committee resolved to reduce the cost of electricity for motive power from 6d. to 4d. for the first hour. The price for the current thereafter will be the same as formerly—1½d. The report of Prof. Kennedy regarding the lighting of the west end was deferred until the committee had had another interview with Prof. Kennedy.

Electric light is to be introduced into West Parish Church.

Barmouth.—A movement is on foot to acquire the old reservoir at Ceilwart whereon to erect the necessary plant for generating electricity.

Bath.—The electric light works insurance is to be increased from £12,000 to £20,000. The insurance company has reduced the premium from 7s. 6d. to 5s. per cent.

Barking.—The clerk reported at the last District Council meeting that the provisional contracts for erection of the electric light station, and for supply and erection of generating plant had been entered into, and that the remainder of the contracts would be completed shortly. As to the electric lighting loan, the present application was for sanction to a loan not exceeding £15,000, and the Local Government Board would require the Council to state a definite sum. The clerk and the engineer are to go into the matter, and report the exact amount required. A letter was received from the Board of Trade, stating that if the Council proposed to make an earth connection, the approval of the Board, with the concurrence of the Postmaster-General, would be necessary, and the clerk reported that he had replied that it was proposed to connect the intermediate conductor of the three-wire system with earth, and that the Board of Trade's conditions would be complied with. The Sunderland Forge Company, Limited, wrote, quoting £825 for the duplicate electric lighting plant required, and £75 for copper pipes, including erection. Consideration was deferred.

Bedford.—The stall-holders in the Bedford Market have requested the Corporation to instal the electric light, and have offered to pay 4d. per night per lamp of 16 C.P., which they suggest would produce £176 3s. 8d. per annum. They are agreeable to amalgamate the stallage and charges for light, pay in advance, and sign an agreement to that effect. They prefer, however, the engineer to undertake the complete installation, owing to their employés inexperience in the *technique* of electricity.

The Town Council has decided to reduce the charge for current to 4½d. per unit (5d. less ½d. for cash in a month) from July 1st. Six transformers of increased voltage are to be purchased for the new area at a cost of £300.

Birmingham.—Estimates have been invited for an electric lighting installation for St. Martin's Church, and the work will be done after Easter.

Bridgend.—The Urban Council recently met in committee to consider the application of a London firm of electrical engineers to take over the Council's provisional order for the electric lighting of the town. A committee was appointed to carry out the negotiations with the firm in question and present a report.

Brighouse.—The Town Council is to take over the electric lighting plant belonging to Mr. Brook.

Chester.—At midnight on Thursday last week the electric light works at Chester, with staff, station, and plant, passed into the hands of the Corporation. Since December 17th, 1896, the concern has been run by the contractors, Messrs. Thomas Parker, Limited. All the staff is taken over, with Mr. F. Thursfield, A.M.I.C.E., as resident engineer, and it is stated that for the future Prof. Kennedy ill not be called in for extensions, &c.

Clerkenwell.—The Vestry had a discussion on electric lighting recently. The members are impressed with the successes of municipal plants elsewhere, including Brighton, and it was resolved to apply for powers to supply the parish.

Dingwall.—The Electric Light Committee on 18th ult. considered the draft agreement to be made between the Town Council and the electric lighting company. The company will have the use of the present lamp-posts, and the installation will comprise eight 500-C.P. arc and nine 32-C.P. and 16 16-C.P. incandescent lamps.

Dorking.—A poll of the ratepayers has resulted in favour of the work of electric lighting being carried out by the District Council.

Durban.—£300,000 is being raised for borough improvements, and £50,000 of this is for electric lighting extensions.

Exeter.—At the last City Council meeeting, the Electric Lighting Committee reported that the lamps for street lighting had been delivered, and examined by an electrician sent from London, who had satisfied himself that they were incapable of being adjusted to meet the requirements of the Council. A correspondence has taken place, says the *Western Morning News*, with Drake & Gorham, the manufacturers of the arc lamps to be supplied, wherein they undertook to make a new set of lamps, properly adjusted to meet the requirements of the Council's system of electric lighting, in lieu of those already delivered, and guaranteed the delivery within five weeks from March 8th. The Council has decided to apply to the Local Government Board for permission to borrow £7,000 for additional plant and cables.

Folkestone.—The prospectus of the Folkestone Electric Supply Company, Limited, has been issued this week. It shows that contracts have already been entered into with the Corporation for lighting the most important streets, including the Lees Promenade. The directors include several local public men, viz., Alderman George Spurgen (chairman), Councillor D. Baker, Councillor S. Penfold (Mayor of Folkestone), and Councillor C. J. Pursey.

Gloucester.—Mr. Hammond attended before the Electricity Supply Committee, and submitted a plan showing how he proposed to arrange the Electricity and Dust Destructor Works upon part of the Bearland estate, and conferred with the Committee as to the various kinds of dust destructors. The Committee approved of the plan submitted by Mr. Hammond, subject to any modifications that may be found necessary in working out the details. Mr. Hammond was instructed to invite the following firms to submit plans and estimates for four dust destructor cells:—Messrs. Beaman and Deas; Goddard, Massey & Warner; Manlove, Alliott & Co.; the Horsfall Syndicate, Limited. The foregoing was approved at a meeting of the City Council on Tuesday.

Greenock.—Representatives of the Corporation are to meet the Board of Trade in London this month in conference on the question of the introduction of the electric light into the borough. The North British Electricity Company, Port Glasgow Town Council, and Gourock Commission, will also be represented.

Hackney.—At the last Vestry meeting, says *Daily Tenders*, a letter was read from an electrical engineer, offering his services in connection with the electric lighting schemes, &c., under consideration. It was decided to receive the letter, the opinion being expressed that it was time that these gentlemen should cease advertising themselves.

Hornsey.—The District Council, which is applying for a provisional order, has refused consent to an application received from Mr. F. J. Hider, inquiring whether he would be allowed to carry the cables for a small electric lighting installation in the Broadway, Crouch End, on the low tension system, over a few thoroughfares, with a view to lighting a few of the shops.

Italy.—The report of the Società Anglo-Romana per l'Illuminazione di Roma shows that its electrical branch is now supplying current to an equivalent of 56,698 16-C.P. lamps. An increase of 4,633 lamps during the past 12 months.

Johannesburg.—The price of current has been reduced to 1s. per unit for dwellings, churches, theatres, and public places. The Council has also reduced the price of gas from 21s. to 20s. per thousand, and increased discounts are given.

Leigh.—The District Council has decided to lay down an electric lighting installation at a cost of £10,000.

Leith.—The plans of the electric light station buildings have been approved at the Dean of Guild Court.

London County Council.—At the weekly meeting of the Council on Tuesday, the adjourned report of the Main Drainage Committee in regard to the proposed electric light installation at the Crossness outfall, to which we referred last week, was adopted. It was decided to approve the estimate of £7,000 for the carrying out of the work, and to invite tenders (1) for the supply and fixing of the engines, dynamos, switchboard, and principal mains, and (2) for the service mains, wiring and fittings.

It will be remembered that early in February the Council decided to ask the Board of Trade to give preference to the orders applied for by the Charing Cross and Strand Electricity Supply Corporation in respect of the Holborn and St. Giles districts over that applied for by the County of London and Brush Company for the same area (which the Metropolitan Electric Supply Company has now power under its Mid-London Order to supply), the reason being that the former company's supply in its present areas is by continuous current, instead of alternating current, which was understood to be the system of the latter company. Since then the Highways Committee has received a letter from the County of London Company, stating that it is prepared to charge at a lower rate than the Charing Cross and Strand Company, and at the same time to supply alternating current by low tension for lighting purposes, and continuous current at 500 volts pressure for motive power. The Board of Trade having intimated its intention to hold an inquiry at which the parties interested should be represented, the chairman of the committee was requested to attend, and to state that, upon the understanding that the County of London Company's supply, if the order be granted, would be given in accordance with the above letter, the opposition of the Council to the granting of the order to the company would be withdrawn so far as related to the rates of charges and the supply by means of alternating current. It would thus be left to the Board of Trade to decide which of the two companies concerned should be allowed to supply the areas referred to in the respective orders. Arising out of questions on this matter, the chairman of the committee mentioned that at the inquiry in question, the Board of Trade decided that it was advisable to leave that area south of Oxford Street to the Charing Cross and Strand Company, and that on the north of Oxford Street to the County of London Company.

As will be seen from the following paragraph from the report of the Highways Committee, the County of London Company has been successful in its appeal to the Board of Trade on the much vexed question of transformer boxes.

The Committee reported:—The Council on December 7th last formally disapproved of the construction of four transformer boxes by the County of London and Brush Company, under its Northern Extension Order of 1897; and against this decision the company appealed to the Board of Trade. The Board gave its award on March 19th, allowing the appeal, and approving the construction of the transformer boxes, subject to the following conditions—(*a*) that the said transformer boxes be constructed in a manner precisely similar to the transformer boxes constructed within the area of the County of London (North) Electric Lighting Order, 1892; (*b*) that there shall be no gas pipe within such distance from any box as is equal in feet to the diameter of the gas pipe in inches. The company has since served a fresh notice, dated March 21st, 1898, of intention to construct the boxes referred to in the previous notice and sanctioned by the award, and has also submitted drawings showing the construction of the boxes as to be in accordance with the conditions attached to the award; and in the circumstances the Council can take no further action in the matter.

Manchester.—The Electricity Committee has adopted a report of its engineer recommending the extension of the Corporation electric lighting plant.

Mexico.—On 8th ult., according to the *Two Republics*, there was a failure in the electric light plant put down by Messrs. Siemens & Halske. It was said to be due to the derangement of the boiler, and of one of the dynamo brushes, and other causes.

Monmouth.—Complaints were made by members of the Council at the last meeting regarding the great delay that had arisen in the completion of the electric lighting installation. Alderman Tippins remarked that a year ago they were told the machinery was all ready, and, further, £1,000 was then paid on account. He also asked why was not the work of laying down the mains proceeding? The chairman's reply, as given in a Hereford paper, was: "I believe the answer is that the making of the turbines was let as a sub-contract, and some delay has been caused thereby."

Salisbury.—It is stated that the electric lighting works will probably be in a position to supply current about the middle of this month.

Southampton.—The electric lighting mains are to be extended down a number of roads. The electrical engineer reports the number of units registered during February, 1898, at 20,288, being an increase of 43 per cent. on that for February, 1897. Mains are to be laid in a number of additional thoroughfares.

West Ham.—Messrs. Ferranti have sent a long letter to the Council, in which they said that they could not undertake to have the engines and other machinery ready before June. The letter, which added that the engineering dispute had hampered them a great deal, was referred to the Highways Committee.

ELECTRIC TRACTION AND MOTIVE POWER NOTES.

Anglesey.—It is suggested by the County Council that the electric line from Garth to Beaumaris should be on the sea or south side of the main road. The promoters proposed to lay it along the opposite side.

Bangor.—It is stated that a number of private gentlemen are setting an electric tramway scheme on foot, the line to run from the far end of the Bangor Pier to the railway station.

Bristol.—A few weeks ago in referring to the position of affairs between the Bristol City Council and the Tramway Company, who desire to go in extensively for electric traction, the word "deadlock" was used to describe the state of affairs. The accuracy of the term is shown by the voluminous report of the Sanitary Committee issued this week for the consideration of a meeting of the Council on April 1st. The document includes the correspondence between the committee and company. The committee, in their first letter of March 3rd, declared the committee would not assent to any arrangement which would involve any extension of the period at which the power to purchase any part of the undertaking would arise and insisted on the condition, No. 10 of their list, which said:—"The date at which the Corporation's power to purchase the power station and proposed extension would arise to be the same as for the present horse tramways." The committee further intimated they would not be able to recommend the adoption of the overhead wire system on some of the existing tramways. The company expressed, in their reply, astonishment at hearing the committee now objected to the overhead system on some lines. The company had no intention of adopting any other than the overhead system which was the only one accepted as practicable by all companies and municipalities in this country dealing with the subject. Insistance on No. 10 would preclude the possibility of further negotiations. In their next letter, of March 9th, the committee modified their position a little. They said: "The committee would be prepared, if all other questions with the company were arranged, to recommend the Council to assent to the use of the overhead system upon all the existing tramways and upon the extensions, on condition that if any other system of electric traction which might appear to the Council to be an improvement on the overhead system were adopted and worked at a profit of 5 per cent. or upwards on the capital employed in five or more towns in the United Kingdom with a population exceeding 50,000, the company would adopt that system on notice from the Council." They also asked if the company were willing the extensions should be constructed by the Corporation and leased to the company for a term of years expiring at the date when the civic power to purchase the horse tramways would arise, at a rent sufficient to cover the interest and annual instalment of the loan for defraying the cost of the work. The company declined both proposals, declared they were anxious to give to the public the benefits of the overhead system of electric traction, and suggested that failing agreement with the Corporation the settlement of a uniform period of purchase by the city be left to the Parliamentary Select Committee. They further suggested the Sanitary Committee might name a period at which all tramways existent in the city or which might be constructed, including so much of the Hanham Light Railway as might be in the city, should be purchasable. The committee in answering varied their condition with regard to calling on the company to alter the overhead system for one deemed preferable, chiefly, by making the towns referred to, have a population of over 100,000 instead of 50,000, and inserting the proviso that the civic demand should be subject to the Board of Trade, regarding it as equitable that the company should make the change. The committee declined to leave it to a Parliamentary Committee to fix a term at which the lines might be purchasable. The company accepted in principle the amended suggestion as to conditions on which they should be asked to change their system, but adhered to their previous determination in regard to condition No. 10 in the list. The horse lines, it should be explained, have about 14 years to run, and the Tramway Company want for the extensions the full 21 years allowed by the Tramway Act. The Sanitary Committee now recommend the Council not to agree to an extension of the period of purchase, and not to agree to a use of the overhead system throughout the tramways; further, that they be authorised to require the company to withdraw the Extension Bill when the Council think fit, and that the Committee be authorised to proceed with the opposition to the Electrical Powers Bill.

Charing Cross, Euston and Hampstead Railway.—The Unopposed Bill Committee of the House of Commons last week passed the Bill promoted by the Charing Cross, Euston and Hampstead Railway Company, which was incorporated in 1893 for the purpose of constructing an underground electric railway between the points named. By this Bill the company is authorised to extend its Charing Cross terminus from the Charing Cross Road to a point under Craven Street, Strand. The Bill also extends the time for constructing the authorised lines until August, 1902, which is two years beyond the time originally granted.

Chesterton.—The British Electric Traction submitted a plan of the proposed route of the Chesterton Tramway to the Parish Council last week for suggestions, and several alterations were proposed.

Christchurch and Poole.—The British Electric Traction Company has proposed a new scheme for electric tramway communication between Christchurch and Poole. The Christchurch Council will grant the Company an interview this month.

Clontarf.—On Saturday last a large number of gentlemen representing the local authorities, accepted the invitation of the Dublin United Tramways Company for the inaugural run to Clontarf and back on the electric system, which has just been completed between Nelson's Pillar and Dollymount. Four special cars were placed at the disposal of the guests.

Dublin.—On 22nd ult. Major Cardew inspected, on behalf of the Board of Trade, the electric tramway from Nelson's Pillar to Dollymount.

Dudley and District.—On Monday at the monthly meeting of the Stourbridge Urban District Council, a draft order of the Light Railways Commissioners with reference to the Dudley and District Light Railway was received, and the Council was asked to send any observations on the same to the Commissioners. The matter was referred to a committee.

Electric Traction for London.—Mr. Douglas Young, in a paper on "London Traffic Problems and their Solutions," read before the Auctioneers' Institute in London on Tuesday, referred to the subject of electric traction. He said that the "enterprising municipalities of Glasgow, Belfast, Leeds, Manchester, Liverpool, Sheffield, Huddersfield, and Birkenhead, to say nothing of many great Continental, American, and Colonial cities, had, after careful experiment or inquiries, arrived at the conclusion that the best discovered system of tramway was that known as the overhead electric system. The electricity was generated at a centre, and conducted along overhead wires, which were either carried from house to house or suspended on ornamental columns with arms. He had seen this system at work in Bristol, Rome, and Milan, and could say that, from an æsthetic point of view, little or nothing was to be urged against it, in fact the pillars or wires suspended from place to place were made to hold the electric lamps, and might be made an ornamental feature. The system was safe, rapid and elastic as to speed, clean, comfortable, and flexible enough to apply to all routes, and met all contingencies of street traffic under ordinary circumstances. It was supplanting all other systems, and in the farther suburbs the prospect of tramcars running in connection with a well-conceived circle system of underground electric railways, opened up a bright future for largely solving the problems of street traffic, and for the comfort and convenience of our people and city.

Fatality.—At Douglas on Thursday, an engineer named Cæsar Brew, employed by the Isle of Man Electric Tramways Company, was attempting to jump on an electric motor car when he slipped and fell on to the line. The car went over his head, almost severing it from the body, death being instantaneous.

Flamborough and Bridlington.—The Flamborough and Bridlington Light Railways Bill has received the formal assent of the Board of Trade in spite of the opposition of the local authority concerned. The work may be expected to be commenced shortly. Messrs. Siemens, Bros. & Co. and Messrs. Whittaker Bros. are the contractors for the electrical plant and the earth work, the civil engineer being Mr. Myers-Beswick, and the electrical engineer Mr. Bernard Drake. Apart from the passenger traffic, which is considerable during the season, the introduction of this line is expected to have an important bearing on the fishing industry of the North, for it is stated that frequently boats which cannot enter Grimsby, will deliver their fish under the shelter of Flamborough Head as soon as facilities for transport exist.

Glasgow.—At an early meeting of the Tramway Committee the proposal to work the new tramway line to be laid in High Street and Castle Street with electricity, in conjunction with the Springburn route, will come up for consideration. There will be sufficient car accommodation and electric power at the Keppochhill depôt to enable the extension to be worked with the Springburn section.

L.C.C. and Electric Traction.—When reporting in February upon the applications for electric lighting provisional orders this session, the Highways Committee expressed the opinion that a clause should be inserted in each order for the protection of the Council's interest in the tramways already purchased, and those to be acquired in the future. At the request of the Committee the following clause was prepared by the Parliamentary Committee:—"If and when the London County Council adopt or permit the use of electrical traction on any of the tramways of the Council, including tramways in any street in which electric lines have been laid down under this order, it shall be lawful for the Council to serve on the undertakers notice in writing requiring them to make such alterations in the position of their lines and works as may be required for adapting such tramway for the use of electric traction thereon, and the undertakers shall thereupon proceed with all reasonable despatch to effect such alteration or removal, at their own cost, and without having any claim against the Council for compensation. Provided that if any difference arises between the Council and the undertakers as to whether the required alterations are necessary for the purposes aforesaid, such questions shall be referred for determination to the Board of Trade, whose decision shall be final." The Highways Committee recommended that the Board of Trade should be requested to insert the above clause in those provisional orders which might be granted in the present or any future session. This recommendation was adopted, the Chairman promising, at the suggestion of Earl Russell, that the clause should be made clear to the Board of Trade to refer only to alterations from a mechanical point of view.

Liverpool.—Thirteen members of the Tramways Committee, accompanied by the Lord Mayor, left Liverpool on Friday afternoon last for Hamburg, to inquire into the working of the electric tramways of that city.

Middlesborough, Stockton and Thornaby.—In regard to this electric line a Middlesborough paper says that the work at the power houses and depôt at Stockton is now in a forward state. The machinery and plant is being rapidly laid down and all the arrangements completed and closed up against the time when the preliminary trials will have to be made.

Ostend.—The Société Anonyme des Railways Economiques de Liege Seraing et Extensions, and the Compagnie Générale des Railways à Voie Etroite of Belgium have just ordered, says *Daily Tenders and Contracts*, a complete electrical equipment from the Westinghouse Electric and Manufacturing Company for a storage battery system traction road in Ostend, Belgium, which promises to prove remarkably successful. The generating plant will consist of a 60 H.P. compound high pressure engine, connected with a Westinghouse multipolar dynamo of 38 kw. capacity, running at 600 revolutions a minute, and producing a current at 280 volts. The cars are to be equipped with a group of batteries and will be able to run 40 miles before recharging. A complete Westinghouse system, with switchboards will be placed in the generating station.

Power Distribution.—On 22nd ult., before the Institution of Engineers and Shipbuilders in Scotland, Glasgow, Mr. Henry Mavor contributed a paper on "Some of the Economic and Practical Aspects of Electrical Power Distribution in Factories." During the past few years, he said, there had been a decided awakening of interest in the possibilities of electrical distribution of power in factories. Long distance transmission of power was of less interest to us in this country because of our local conditions. In reference to the power scheme for the Midlands, he said that it seemed probable that the operation of such a scheme would only be commercially practicable in districts where the local authority does not control the electric supply, because, when the local authority has to be dealt with, the price obtainable from it would not exceed the rate at which it could itself produce the power without any allowance for profit. On the other hand, there was undoubtedly an enormous field for the electric motor among small users of power who could obtain the electric current at a moderate rate from supply companies or local authorities. The lecturer divided power consumers into various groups —(1) The case of factories, chiefly textile, where the power is delivered from one large engine from gearing or belting of machinery closely grouped round the source of power, such as spinning and weaving factories; (2) in the case where the nature of the work is such that the power must or ought to be delivered direct at the point where it is applied to the work. This included factories and works where the machines to be driven were widely divergent in character, were widely spaced, and run at different and varying loads and speeds, as in paper mills, print works, chemical works, steel works, foundries, shipyards and many engineering establishments where work of a varying character is to be accomplished. In the latter group the lecturer considered there is a very wide field for the application of electric power distribution in the Glasgow district.

South Staffordshire.—At a meeting of the Tipton Council on Tuesday, a letter was submitted from the Board of Trade enclosing a communication received from the South Staffordshire Tramways Company respecting the renewal of steam licenses, but it was stated by the chairman that the Council would not take any further action in the matter until an application was made for Parliamentary powers for the use of electric traction.

Stourbridge.—The Urban Council has received the draft order of the Light Railway Commissioners relative to the Dudley and District Light Railways. The Council was asked to consider the draft, and if it had any representation to make, to do so by April 7th. The order proposed to give the promoters three years to finish the work in, but a representative of the British Electric Traction Company stated that the existing tram line would be converted and the electric trams running in the present year. The draft order was referred to a committee.

The "Underground" and Electric Traction.—The Metropolitan Railway Bill, under which powers are sought to work the lines by electricity, was before a committee of the House of Commons on Monday. Mr. Littler, Q.C., opened the case for the promoters, and Mr. John Bell, the chairman of the Company, gave evidence in support of the Bill. The Great Western Railway Company appeared in opposition, and with respect to this, Mr. Freeman, Q.C., speaking on behalf of the promoters said:—"I may say that under the Bill as drawn, if the Metropolitan Company satisfy themselves that electric traction is the proper power to use on the railway we shall require the Great Western to alter their engines to suit the new conditions. Their engines would be under our control, but if they objected they would then have power under previous agreements to take us to arbitration." Mr. John Bell stated that if the Metropolitan had to make an enormous change for the benefit of the public he did not see that the Great Western would have any ground of complaint if they were compelled to do the same with regard to the few trains that run over the system in the course of the day. If the electric traction is the success they expected it would be they would not extend the electric traffic to Aylesbury. They did not propose to go further with it than Swiss Cottage. Sir John Wolff Barry, engineer to the company, and Sir Benjamin Baker, gave evidence for the promoters on the engineering aspect of the scheme.

The committee sat again on Tuesday to consider the Bill. Mr. Pember, Q.C., for the Great Western Company, briefly addressed the committee, contending that, if his clients were forced to adopt electric traction, they should be compensated for the extra expense involved in the provision of electric engines and rolling stock. He submitted for insertion in the Bill a clause drawn up by the petitioners to the effect that nothing in the measure should prejudice the working of agreements already in existence, and that questions as to the method of carrying out the proposed change should be referred to arbitration as well as any alterations that might be necessary in Great Western engines and rolling stock, and any alterations in working, and also the question of cost. Mr. Freeman, Q.C., replying for the promoters, said the company were proposing to incur this great expense simply and solely to improve the conditions of working the traffic. The Great Western Company, who were virtually partners in the railway, would be equally benefited so far as their traffic over the line was concerned. His company were prepared to safeguard all the rights of the Great Western Railway Company, and to do this his company would consent to the inclusion in the Bill of a clause providing that, should the Metropolitan Company at any time require the Great Western to substitute electric traction for steam locomotion on any of the trains of the Great Western Company working over the Metropolitan Railway, either of the companies should be entitled to refer such requirement to arbitration as if the same had been included under the terms of the existing agreement. He submitted that it was unreasonable to expect that the Metropolitan Company should pay the expense of converting the rolling stock of the Great Western if, under the pressure of public opinion, it became necessary for that company to follow the example of the Metropolitan Company and use electricity. The chairman asked if the petitioners doubted whether electricity would ever be used on the railway. Mr. Worsley Taylor said they acknowledged that electricity might be useful, but were of opinion that to adopt it might involve great changes in the rolling stock, and that before they were called upon to pay for the change the subject should be threshed out before an arbitrator. After some further conversation, the chairman said there was no opposition to the suggestion that sooner or later electricity would have to be used on the Metropolitan Railway, and, as the Great Western Company were to a great extent parties to the working of the railway, the committee felt that in making the great change which was not contemplated in 1869, there should be some special clause introduced into the agreement. Time was allowed to the parties to prepare a clause. In the course of the proceedings the chairman said that the committee were satisfied that there was every prospect of electric traction being used on the railway. The committee sat again on Wednesday and adjourned.

Waterloo and City Railway.—It is stated by a morning contemporary that there is talk of running the first train over this line on Monday, May 2nd.

Whitley.—A public meeting, on 24th ult., approved of the proposal of the British Electric Traction Company to establish an electric tramway from Cullercoats through Whitley, and suggested that it be carried on to the sea front at Monkseaton Lane. Mr. Frank B. Lea explained the scheme. The opposition was weak as water, but it was certainly novel, for a Mr. Saint "expressed the fear that the introduction of tramways into the district would give facilities to persons to travel more easily beyond the three miles limit on a Sunday to obtain drink. He also regarded the trams as a danger to children."

The Telephone Service.—According to Wednesday's *Standard*, Mr. Faithfull Begg proposes to bring forward an amendment to Mr. Caldwell's resolution with regard to the telephone system which will be moved on going into Committee of Supply on the Civil Service estimates to-night (Friday). The amendment is to the effect that the acquisition by the State of the whole telephone system of the country is the only solution of the difficulties which exist, and are increasing under the present system of licences. The amendment can only come on in case Mr. Caldwell's resolution is carried.

(*Continued on page 447.*)

TORQUAY MUNICIPAL ELECTRICITY WORKS.

As we briefly announced last week, the municipal electricity works were formally opened on March 17th.

The municipal authority of Torquay obtained powers to undertake a public supply of electricity as far back as 1891; but it was not until 1896, when there was some danger of the provisional order being revoked, that the Corporation really determined to erect electricity works. Mr. Trentham, who had previously prepared reports on the subject, was entrusted to prepare a plan and specifications, which were adopted by the Council, and have since been carried out.

The system that has been adopted in Torquay is a high pressure alternating current supply; the pressure at the consumers terminals being 200 volts, the street lighting being done by means of arc lamps using rectified currents. An unusual feature about the works is, that, subject to modifications, a building was ready to hand in the shape of large and lofty coal cellars owned by the Corporation. The cellars can scarcely be said to be underground, being, as a matter of fact, formed from excavations made under a high level road, entrance to them being from a low level road adjoining the harbour. Although provided with four walls for housing the generating plant, it was necessary to carry out important alterations to adapt the cellars for electric lighting purposes. For instance, it has been necessary to excavate for the purpose of making foundations for the machinery. This operation entailed the removal of 300 tons of limestone rock, which had, for the most part, to be blasted. The machinery now rests upon a solid block of concrete, which is isolated from the adjoining walls by means of hair felt. It was discovered, at the conclusion of the excavations, that at times of very high tide sea water percolated through the walls, and to avoid this the lower part of the excavations has been concreted. An ordinary wide road divides the works from the harbour, and this contiguity to the sea provides facilities for obtaining seaborne coal; moreover, it gives an abundant supply of water for condensing purposes.

"Where's the chimney?" was propounded as a sort of conundrum on the opening day, and certainly, to one who is accustomed to look upon a tall chimney as a guide to electricity works the matter was slightly perplexing. As a matter of fact, the chimney shaft passes up through an adjoining building, owned by the Corporation and utilised for concerts and entertainments, the top of the chimney being no higher than the roof of the building. In consequence of the chimney being restricted to a height of 60 feet, forced draught has been resorted to.

The internal appearance of the dynamo room by no means suggests anything of the cellar; the room is lofty, of a considerable size, and is well lighted. An excellent idea of the arrangement of plant will be obtained from the general view of this room. The boilers are placed in an adjoining room, which has been permitted to retain much of its underground attributes.

Laying the Mains.

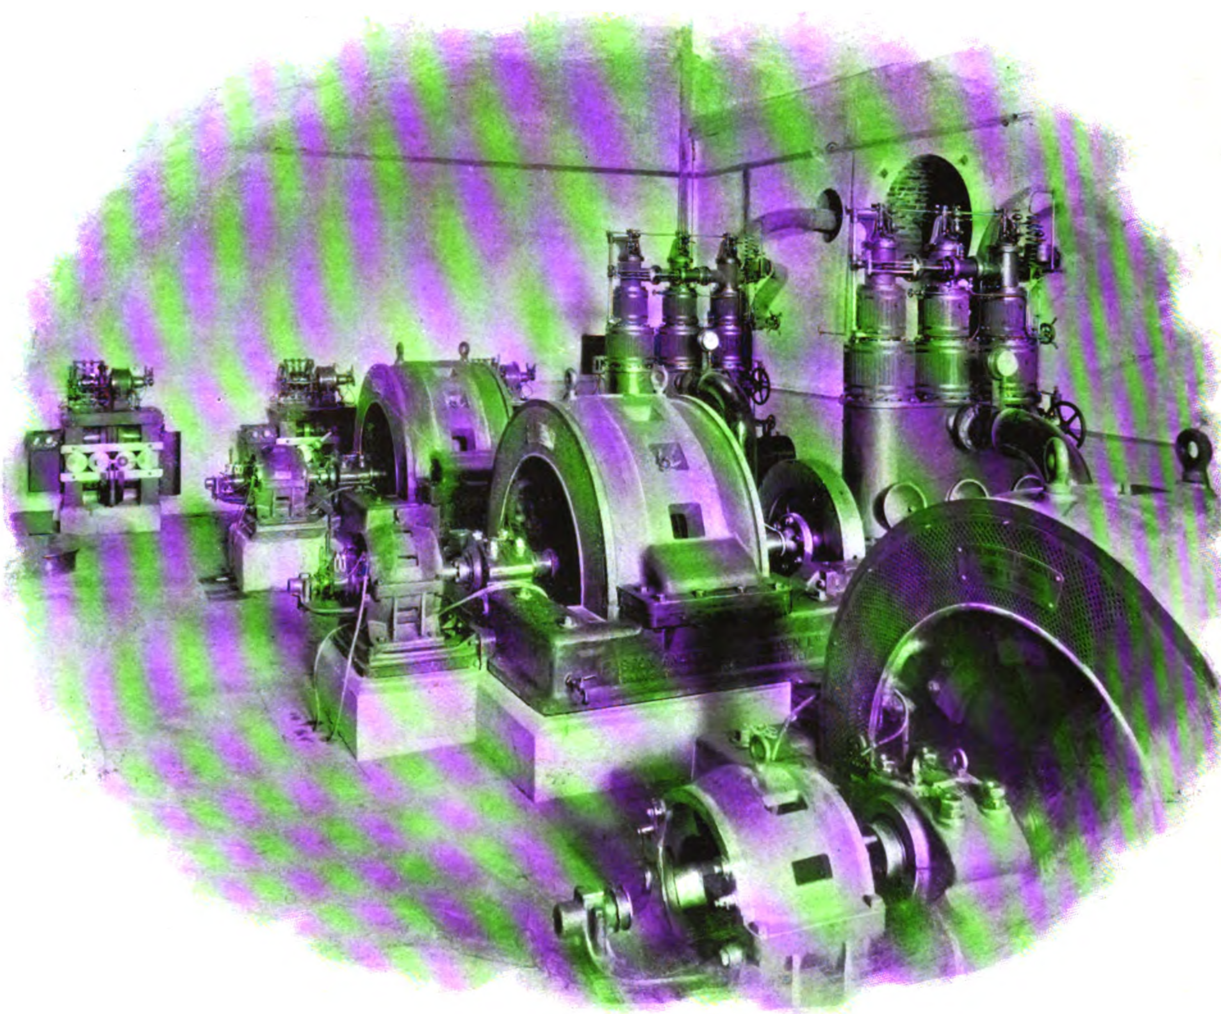
Coming to the more prosaic details of plant, we will begin with the boilers, of which there are three, each having 1,619 square feet of heating surface, and 30 square feet of grate area. Each boiler is composed of eight sections of tubes, each tube being 18 feet long.

The horizontal steam and water drum is 3 feet 6 inches in diameter and 22 feet 7 inches long. Each boiler is complete with the usual fittings, including Hopkinson's safety valve, stop valve, blow-off valve, &c. The fact has been mentioned that forced draught is necessary, and each boiler is, therefore, fitted with steam blowers for forced draught. In addition there is a Babcock & Wilcox patent superheater, having 226 square feet of heating surface, and consisting of 32 drawn steel tubes $1\frac{1}{2}$ inch in diameter, connected at the ends to a wrought steel cross box, the tubes being fastened therein by expansion. The upper cross box is connected to the steam and water drum by two 4-inch steel tubes expanded into a nozzle provided for the purpose, and at the upper end of these tubes there is a cast-iron dry pipe. Prevention against overheating during the time of raising steam is insured by the arrangement for flooding the superheater, and using the superheater then as part of the heating surface of the boiler, although if the flooding is omitted, when raising steam, damage is not likely to result if the fire is not forced too rapidly.

In conjunction with the steam raising plant there is the inevitable Green's economiser, which is made up of 192 pipes, and fitted with the usual safety valves, thermometer, scrapers, &c.

In a triangular apartment between the engine room and the boiler cellar are the pumps for feeding the boilers and for the condensing water.

The boilers are fed by two Worthington duplex feed



Engines and Dynamos.

pumps, each having a steam cylinder 5¼ inches diameter and a water cylinder 3½ inches diameter, the length of stroke being 5 inches.

Before passing on to consider the other plant, it may be mentioned that, though no detailed tests have yet been made to show the effect of the superheater, the steam is apparently very dry, there being, as a rule, no water deposited in the separators. The fuel at present used is a mixture of

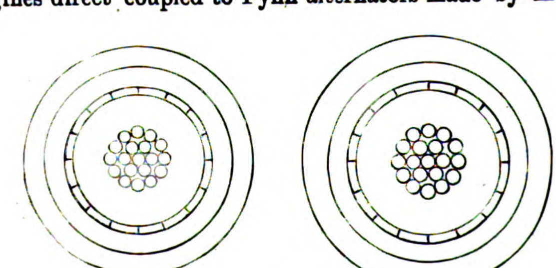
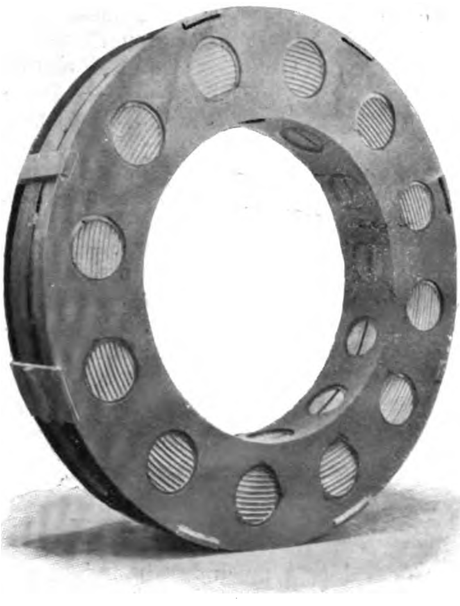
three parts of coke to one of Welsh coal, the price of the former being 12s. and of the latter 20s.

We have already referred to the interior of the dynamo room. The plant at present erected consists of three Willans engines direct coupled to Fynn alternators made by Messrs.

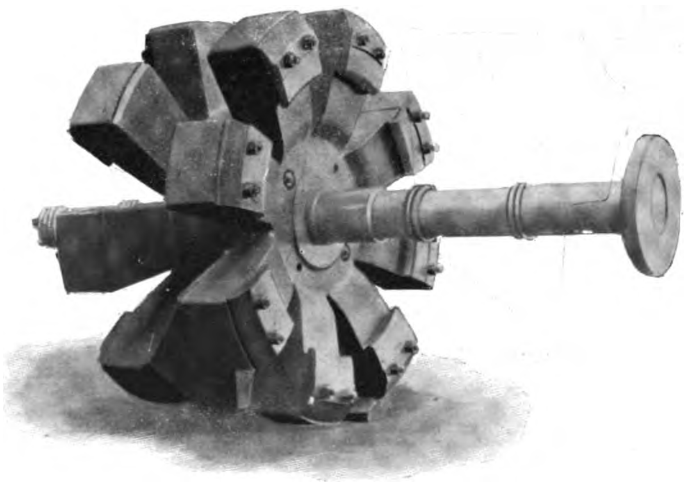


H.T. concentric.
19/15 S.W.G. section ·079. 19/14 S.W.G. section ·0976

Easton, Anderson & Goolden. The engines are of Willans three-crank compound condensing type working at a steam pressure of 130 lbs., and developing 200 B.H.P. The alternators, to which we have not had previously an opportunity of referring, are of the inductor type, running at 380 revolutions and having a ~ of 50. The armature forming the outer frame of the machine, the field magnets (the



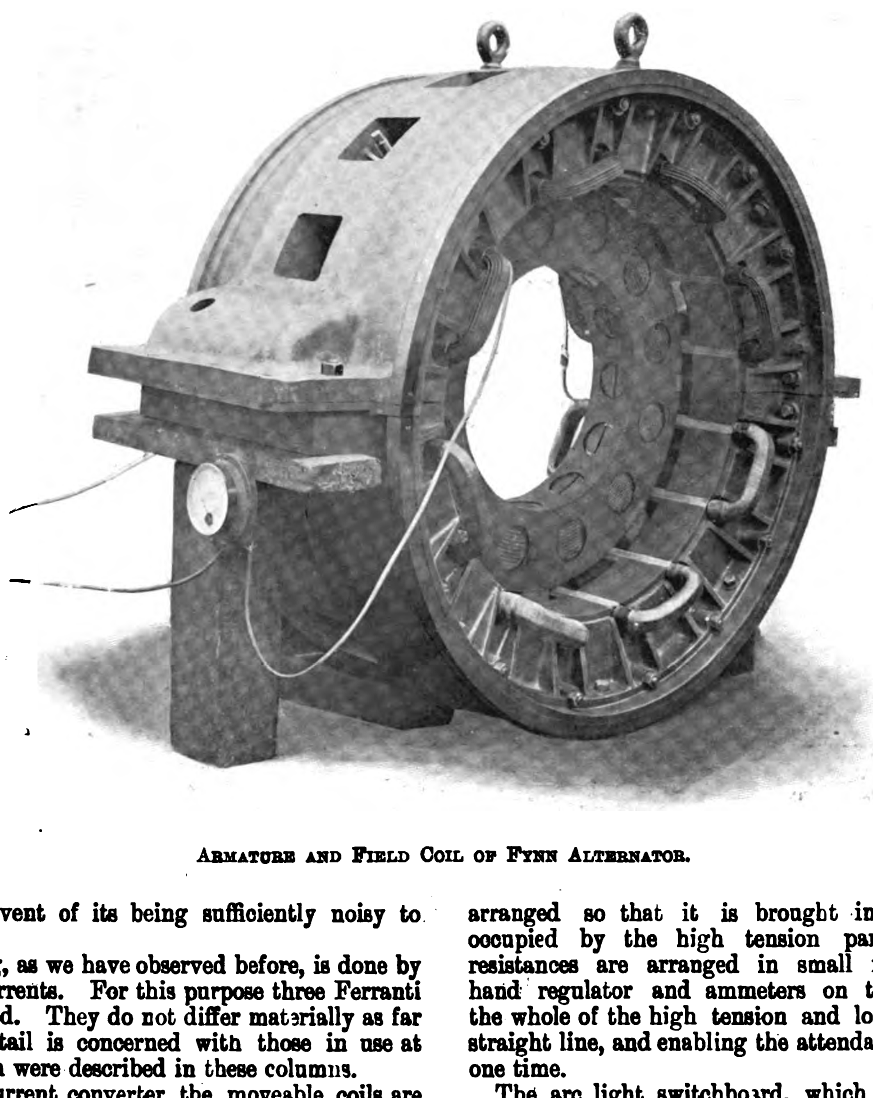
Field Coil of Fynn Alternator.



Field Magnets of Fynn Alternator.

revolving part) being mounted on the main shaft of the alternator.

There are eight armature coils in each machine, which are wound with stranded double cotton-covered cable. The coils are laid in paper tubes, and laid in slots in the laminations. Inside the armature frame is placed the field magnet coil, which is supported on brackets, this being shown in one of the illustrations. The field magnet coil occupies a position in the completed machine, between the poles of the revolving field magnets. It will be observed from the illustrations that the two circles of pole pieces are so arranged, that the poles in one circle are opposite the gaps in the other circle. The inside diameter of the armature is 4 feet 6 inches, and the width is 40 inches.



Armature and Field Coil of Fynn Alternator.

The alternators have been specially designed for noiseless running, there being a stringent condition in the specification compelling the contractor to remove the machinery to another site in the event of its being sufficiently noisy to create a nuisance.

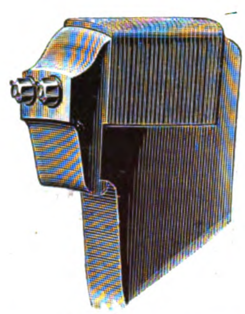
The street lighting, as we have observed before, is done by means of rectified currents. For this purpose three Ferranti rectifiers are employed. They do not differ materially as far as constructional detail is concerned with those in use at Hammersmith, which were described in these columns.

In the constant current converter, the moveable coils are supported on toothed wheels which gear into a rack. On the top of the constant current converters is mounted a base plate carrying the alternating current motor, and on the end of the shafting of the alternating current motor is arranged the high tension commutator with its rocker and brushes complete. At one side of the constant current converter is attached the two-unit converter required for running the alternating current motor, and on the other side is attached the water break switch which is connected in series with the arc lamps.

The switchboard is similar in construction to the now well known type of Ferranti switchboard, the board being composed of slatework partitions, so as to be thoroughly fireproof throughout. Each partition forms a separate dynamo, or circuit panel, each one being provided with a special spring break switch.

Each panel is provided with a duplicate set of fuse contacts and oil break fuses, the arrangements enabling any fuse to be withdrawn and examined whenever desired without interfering with the working of the circuit. On each panel is arranged a vertical scale ammeter. The bus bar is arranged on the ring main system, enabling any circuit to be isolated and the remainder of the circuits to be run without interference. The usual synchronising arrangements are provided. Low tension gear is also attached to this board and is arranged so that it is brought into the 6-inch centres occupied by the high tension panels above it. The resistances are arranged in small resistance boxes, with hand regulator and ammeters on the top, thus placing the whole of the high tension and low tension gear in one straight line, and enabling the attendant to attend to both at one time.

The arc light switchboard, which is placed near to the rectifiers, is arranged for controlling three rectifiers and the respective circuits; it is, however, arranged to enable any new rectifier to be connected at once on to any circuit or any rectifiers running any number of circuits together. It is provided with a plug box on the bottom of the board, which plug box receives the current from main board and distributes it to each rectifier through an independent fuse. The plugging arrangement of this board is noteworthy, the plugs being attached to flexible cords and weighted with a



Showing Methods of Fixing Pole Pieces in Fynn Alternator.

pulley, so that when not in use they are kept in a fixed position. Each circuit is provided with an ammeter and pole indicator. A voltmeter is arranged with a plug and a pair of flexible cords, plug sockets being fixed for each circuit panel, so as to enable one to ascertain the voltage of any circuit.

The outside work reveals nothing that can be considered very novel. The low pressure distribution is accomplished from scattered transformers placed in the roadway. The street lamps are not placed on alternate mains, but one main feeds the whole of the lamps in one part of the town and other mains supply current to other sections.

The transformers are of the Berry type, and have been made by Messrs. Nalder & Harrison. The sizes are 30 kw., 20 kw., and 10 kw. In most cases they are placed in sheet steel cases, which are in turn placed in cast-iron road boxes, which have separate spaces for the high and low tension switches and fuses.

We illustrate some of the sections of the mains in use which have been laid by the British Insulated Wire Company.

Some of the high tension cables are laid in Doulton conduit, and some are laid in wooden troughs filled in with a hard-setting compound. The low tension cables are double steel armoured, and laid direct in the ground.

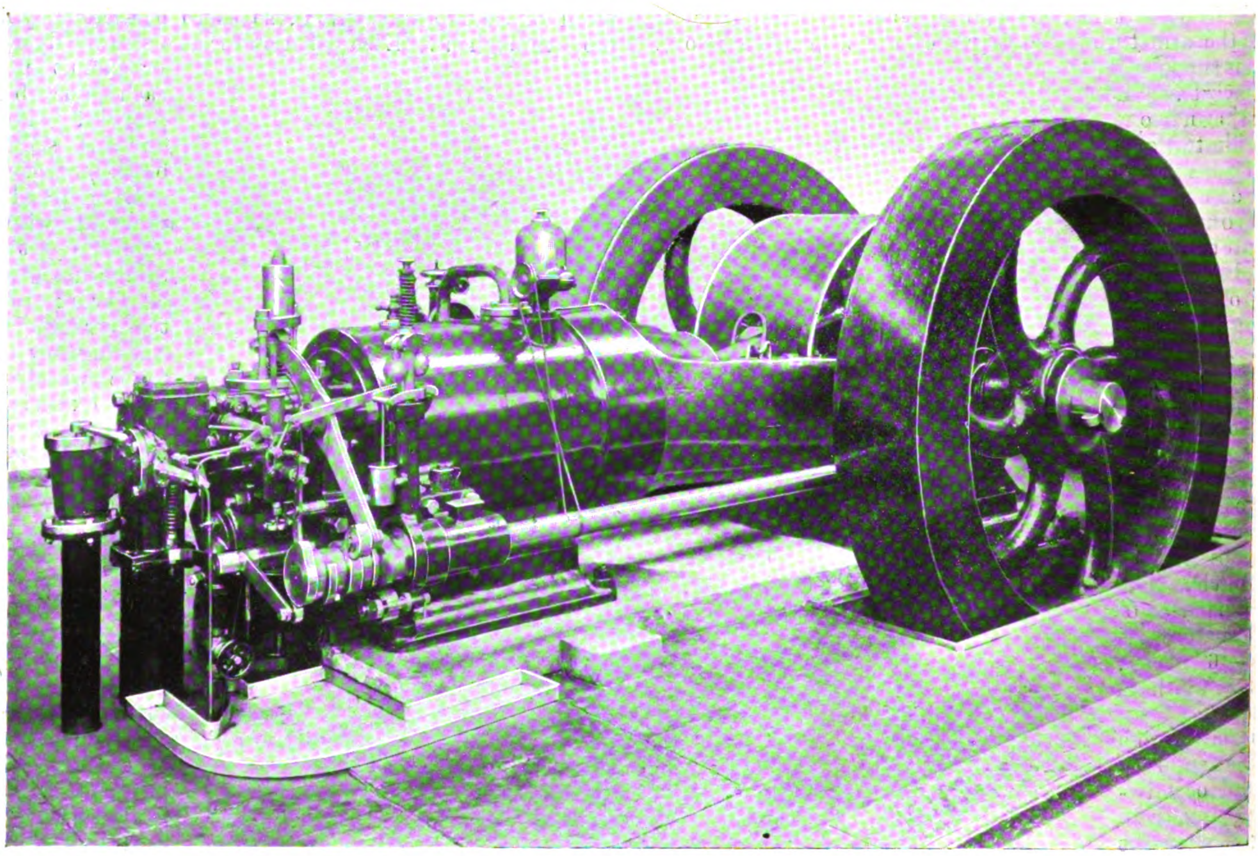
The arc lamp columns (which are supplied with overhanging brackets) have been supplied by Messrs. James Allen, sen. & Sons, of Glasgow, and the arc lamps are of the Crompton-Pochin type.

The demand indicator system is in use, and at the opening ceremony 3,600 8-C.P. lamps had been connected, which augurs well for the future prosperity of the works.

The principal contractors are as follows:—Boilers, Messrs. Babcock & Wilcox; engines and alternators, Messrs. Easton, Anderson & Co.; cables and street work, British Insulated Wire Company; switchboard, Messrs. Ferranti, Limited; transformers, Messrs. Nalder & Hilton; crane, Messrs. Isles, Limited. Mr. Trentham, the consulting engineer, is to be congratulated upon bringing the lighting of Torquay to a successful issue in the face of much opposition and difficulty.

100 H.P. GAS ENGINE.

It cannot be denied that much has been done during the past few years to develop gas engines for electric lighting. One of the latest types that has been specially designed by Messrs. Fielding & Platt for the driving of dynamos is one of 100 H.P., which was exhibited at the Brussels Exhibition, an illustration of which is given here. As far as we can learn, the cyclical variation in this engine does not exceed $\frac{1}{2}$ volt. This result is obtained by having an impulse at each cycle, no matter what the load may be, from no load to full load. The method in which this is carried out is very satisfactory, so that, even when running absolutely light, the charge is stated to be fired with the greatest certainty.



Fielding & Platt 100 H.P. Gas Engine.

The cylinder has a diameter of 20 inches, with a stroke of 27 inches, the crankshaft being 8 inches in diameter in the main body, whilst the crankpin is 11 inches in diameter, the main bearings being 14 inches in length, and the crankpin 10 inches. The crank is balanced by a pair of counterweights strapped to the crank throws, and continuous lubrication of the crankpin is provided for by an annular oil channel, into which the oil is dropped from a fixed sight-feed lubricator. The engine was designed for driving two dynamos, one from each fly-wheel, the latter weighing about 5 tons each.

The engine is fitted with Fielding's self-starter, the action of which is as follows: The crank being placed at an angle of about 15° above the near dead centre, gas is admitted to the combustion space, and an outlet opened near the flame of the Bunsen burner, which heats the ignition tube; this outlet permits of the escape of air as the gas enters. As soon as the gas begins to escape along with the air, a blue flame is formed; and as the proportion of gas to air increases, the colour of the flame gradually changes to a yellow luminous flame. As soon as the flame indicates that the escape is practically all gas, the outlet is closed, and the gas shut off. All that is required now to start the engine is to admit compressed air, which, entering the clearance space, rapidly mixes with the gas, forming a highly explosive compound under a pressure of usually about 60 lbs. per square inch.

Before sufficient air can obtain admittance to form an actively explosive mixture, the piston is put slightly into motion for a short distance until the explosion takes place, whereupon the motion of the piston is greatly accelerated, and the engine is put into action with sufficient force to enable the ordinary cycle to follow on.

The compressed air is stored up by the engine itself into a small reservoir, the energy stored up in the fly-wheels serving for this purpose, the gas for the moment being cut off, and when required, a separate charging pump is fitted, worked either by hand or by power, but as a rule this is unnecessary.

TELEGRAPH AND TELEPHONE NOTES.

(*Continued from page 442.*)

The Bolinao Cable.—A telegram in the daily press, dated Singapore, March 23rd, stated that the telegraph steamer, *Sherard Osborn*, was leaving there for the Philippines for the purpose of transferring the Bolinao cable to Manila. The transfer will be permanent.

Direct Cable to Cuba.—The following is a translation of an article appearing in *El Imparcial re* the above cable:—"The Ministry of the Interior has reported favourably on the tender for the laying of a direct cable between the Peninsula and the island of Cuba. The cable will land at Cadiz, Santa Cruz de Tenerife, Nieques (an island situated 15 kilometres to the east of Porto Rico), and finally, at Havana. The cable will not, contrary to the interest of the nation, be laid to St. John, Porto Rico, as the company owning and working the cables in the lesser Antilles have exclusive landing rights for 40 years at that island, and for this reason neither the Government or any private company can establish telegraphic communication which they may consider necessary. The report has already been passed on by the Minister of the Interior to the Minister for the Colonies for the embodiment of Government rights and privileges, and the decree calling for tenders for the laying of the cable will soon appear." Another paragraph states:—"The Minister of the Interior had an interview with the Minister of the Colonies for the purpose of preparing the report asked for by the Council of Ministers on the cable between the Peninsula and Cuba. The report will deal with two proposals, one being for the construction of the direct cable, and the other for a branch cable from Havana to Hayti to connect there with the French system."

Another issue of the same paper states:—"The news that the Ministers of the Colonies and the Interior have been entrusted by their colleagues in the council with the decision regarding the matter of the direct cable to Cuba, and, further, that there are two proposals to be dealt with, viz, (1) offering to construct a direct cable, and (2) a branch cable from Havana to Hayti, there to be connected to the French system, has given rise to certain fears, which we find to have serious foundations, as by the latter scheme we should merely be ridding ourselves of the control of our communications by Great Britain and the United States to transfer it to the French. The *Nacional* states if the direct cable is not to be laid, rather than allow all the traffic to be handed to the French Cable Company, let the state of affairs remain as at present. Our contemporary asks for more light upon the subject from the Ministerial press, and we join in the demand, as we endorse their opinion."

Glasgow Telephone Service.—On 24th ult., the Corporation deputation had a private interview with the Postmaster-General, at Norfolk House, on the subject of granting a municipal telephone license for Glasgow. Various points were enlarged upon by the deputation, and the Duke expressed his desire to act impartially. He asked if the granting of a license conditionally might not be held to prejudice any opposition. The deputation replied that they were perfectly willing that the granting of a conditional license should be so safeguarded and hedged in as to leave most unfettered discretion to Parliament in dealing with the Corporation's proposals. In the course of the conversation the deputation repeated the decision of the Town Council under no circumstances to grant the telephone company the right to utilise the streets. The Duke of Norfolk assured the deputation that he thoroughly understood the position, that he would give it his careful consideration, and that he would communicate with them shortly.

Secrecy of Telegrams.—We understand that on 22nd ult. a notice was issued by the Postmaster-General to the postal staff, calling attention to a question recently addressed to the Secretary to the Treasury in the House of Commons upon the subject of the secrecy of telegrams. The construction of private apartments in postal telegraph offices was advocated as a means of greater privacy being secured to the public while handing in telegrams. The Postmaster-General enjoins the counter clerks to deal with telegrams in such a manner as to preclude them being read by the public.

The Telephone Service.—About 20 members of Parliament, under the presidency of Mr. Provand, met at the House of Commons on 24th ult., and decided to put down a motion in favour of the Post Office granting licenses to local authorities to work telephones of their own.

In the Commons on 22nd ult., Sir M. Stewart asked the Secretary to the Treasury, as representing the Postmaster-General, whether any judicial decision has ever been given that a telephone instrument is equivalent to a telegraph except as regards the Postmaster-General's monopoly of the right of conveying messages by wire.

Mr. Hanbury, in reply, said the decision that a telephone is a telegraph was given by the Exchequer decree of the High Court of Justice in the case of the Attorney-General *v.* the Edison Telephone Company. This case arose on the right of the Postmaster-General to a monopoly to conveyance of messages by wire. The exact words of the judgment, "For all these reasons we hold that the telephone is a telegraph within the meaning of the Acts of 1869 and 1863," are very wide.

A sub-committee of the Hull Corporation has been going into the question of the telephone charges and service generally, with the National Company's officials.

CONTRACTS OPEN AND CLOSED.

OPEN.

Accrington. — April 19th. The Corporation wants tenders for the supply and erection of three sets of steam dynamos, each set consisting of a triple expansion condensing steam engine of the inverted vertical type, 90 I.H.P., and of a shunt wound dynamo. Also a feed water heater, storage battery having a capacity of 750 ampere-hours, switchboard instruments, apparatus cables, wires, street boxes, connections, &c. For further particulars see our "Official Notices" this week. Consulting engineer, Mr. J. N. Shoolbred, 47, Victoria Street, S.W.

Ashton-under-Lyne. — April 5th. The Corporation invites tenders from firms willing to undertake the free wiring of premises in the Borough. Consulting engineers, Messrs. Lacey, Clirehugh & Sillar, 78, King Street, Manchester. See our "Official Notices" March 25th.

Bournemouth.—April 4th. The Corporation wants tenders for motor vehicles for the collection of house refuse, &c. Borough engineer, Mr. F. W. Lacey. See our "Official Notices" March 18th.

Derby.—April 12th. The Corporation wants tenders for the electric wiring of its Ford Street yard and premises. See our 'Official Notices" March 18th.

Derby.—April 11th. The School Board want tenders for the electric wiring of the Traffic Street Board School, Derby. Particulars from Mr. J. E. Stewart, Corporation electrical engineer. See our "Official Notices" March 25th.

Edinburgh.—April 23rd. The Midlothian and Peebles Lunacy Board is inviting tenders for the installation of electric light in the Asylum at Rosslynlee, near Edinburgh, including (1) generating plant, accumulators, switchboard, &c.; (2) wiring, fittings, &c. Particulars may be obtained on application to Prof. Bailey, Heriot-Watt College, Chambers Street, Edinburgh.

Leyton.—April 4th. The District Council wants tenders for the supply of two dynamos, one transformer, two gas engines and connections, and switchboards for extension of the electricity works. Electrical engineer, Mr. H. C. Bishop. See our "Official Notices" March 18th.

Manchester.—April 4th. The Lancashire and Yorkshire Railway Company is inviting tenders for various stores. The following are a few of the items:—5. Copper; 7. Copper tubes for boilers; 8. Copper tubing; 29. Signal and telegraph fittings; 30. Signal, telegraph and electric light wires. Samples may be seen and forms of tender and further particulars obtained at the Stores Department, Osborne Street, Manchester.

Shoreditch.—April 12th. The Vestry wants tenders for the supply and erection of arc lamps and accessories, also for electric light cable. Electrical engineer, Mr. C. N. Russell. See our "Official Notices" March 25th.

Switzerland.—April 30th. Plans and estimates are being invited, says the *Contract Recorder*, by the Government authorities of Fribourg, Switzerland, until April 30th next, for a projected electricity generating station to be established at Hauterine. Water-power is to be utilised, and the station will have a capacity of about 6,000 H.P. A premium of £120 will be awarded to the three schemes submitted which are considered to be the best. Plans and estimates are to be sent to the Department des Travaux Publics, Fribourg, Switzerland, from whence full particulars of the competition may be obtained.

The War Office.—April 27th. The Secretary of State for War is prepared to receive offers, competitive designs and specifications for the supply of portable electric search light apparatus. Particulars from the Director of Army Contracts, War Office, Pall Mall, S.W. See our "Official Notices" February 4th.

Victoria.—June 24th. The Council of the city of Hawthorne (Colony of Victoria, Australia) is inviting tenders for the supply and erection of buildings, boilers, engines, dynamos, transformers, mains, meters, arc lamps, poles; also running the plant for three years. See our "Official Notices" March 11th.

CLOSED.

West Ham.—The Town Council has accepted the tender of Messrs. H. J. Rogers & Co. (£712) for wiring the public buildings for electric lighting. The Council hopes to be able to supply electricity to consumers in September next.

FORTHCOMING EVENTS.

1898.

Friday, April 1st, 8 p.m.—Institution of Junior Engineers at the Westminster Palace Hotel. Paper on "Mechanical Refrigeration," by Mr. J. T. Burrell, of Peterborough.

Royal Institution. Lecture by Prof. Dewar on "Liquid Air as an Analytic Agent."

Saturday, April 2nd, 11 a.m.—Visit of the Institution of Junior Engineers to the Thames Iron Works, Blackwall.

Tuesday, April 5th, at 8 p.m.—Röntgen Society, at 11, Chandos Street, Cavendish Square, W. Paper by Mr. James Wimshurst upon "The Influence Machine and its Advantages for lighting X-Ray Tubes."

At 8 p.m.—The Institution of Civil Engineers. Paper to be read (time permitting) on "The Electricity Supply of London," by A. H. Preece, Assoc.M.Inst C.E.

NOTES.

In Honour of M. Gramme.—By royal decree on December 30th last, M. G. Gramme was nominated Commander of the Order of Leopold. On this occasion the international jury of the electrical sections of the Brussels Exhibition of 1897 decided unanimously to organise at Brussels a demonstration in honour of the celebrated Belgian electrician, and to celebrate his admission into the Order of Leopold by a banquet, to which electricians of all countries should be invited. The date of this celebration was fixed for March 27th, and it was to be commemorated by a medal, two impressions of which were to be struck, one in gold, and one in silver, to be forwarded to M. Gramme on the day of the banquet. Senator Montefiore Levi, founder of the Electro-technical Institute of Liège, honorary president of the Belgian Society of Electricians, and of the Association of Engineers from the Montefiore Institute, accepted the post of honorary president of the committee formed for the organisation of the demonstration, M. Mascart being the acting president. The subscriptions were received by M. Alfred Roosen, secretary of the organisation committee, Rue Vould, 64, Brussels.

Our Torquay Photographs.—The views of the central station and the operation of laying the mains given in our article on the "Electric Lighting of Torquay," have been prepared from photographs taken by J. C. Dinham, Torquay.

A New Departure in Incandescent Lamps.—Prof. Nernst, the well-known electro-chemist, has recently been experimenting with the view of discovering a better filament for the glow lamp, and has produced a lamp which is decidedly more efficient than the present filament. It remains to be seen whether the new filament will be more durable. According to recent theories of electrolysis, all electrolytes are more or less dissociated when dissolved in water, and it is these dissociated molecules which carry an electric current through the electrolyte. If none of the molecules of the electrolyte have been dissociated, no current will pass, except the E.M.F. of the current is exceedingly high. Dissociation of the molecules of electrolytes may also be brought about by heating them to a high temperature, and they become conductors of electricity in the same way as when they are dissociated by solution. It is this fact that has been utilised by Nernst in the construction of his new electric lamp. A thin rod of magnesium oxide, calcium oxide, or such like compound, is heated, in the first place, by a Bunsen burner to a red heat, and an electric current is then passed through it. If this current is sufficiently strong to develop enough heat to replace that which is given off, then, when the Bunsen burner is withdrawn, the current will maintain the rod at a white heat. A practical objection to this lamp is the preliminary heating; such lamps would, in fact, have to be lighted like the old-fashioned gas or paraffin lamps. The ingenuity of inventors may, however, yet overcome this difficulty. Since the temperature of ignition of the lamp depends on the electrolyte which is used, it is important to know which of these substances become conducting at the lowest temperature. With rods of equal dimensions, calcium oxide requires the oxyhydrogen blowpipe to bring it to the required temperature, while it is possible to start magnesium oxide by heating with a Bunsen flame. Nernst uses in his lamps magnesium oxide, which can be bought in the form of rods, and he recommends that the lamp should be ignited by the discharge of an induction coil. The ignition by the induction coil is not likely to be used in practice. Another method which has been proposed [*Zeit. f. Elek.*, Vol. 16, p. 103] is to embed a carbon filament in the magnesium oxide or other electrolyte made use of. When the rod is cold, the carbon filament will form a path for the current, and gradually communicate sufficient heat to the surrounding electrolyte to raise it to the conducting temperature. Platinum could not be used instead of the carbon, because it would fuse at the very high temperature developed in the Nernst lamp; and besides, all metallic threads would shunt too large a fraction of the electric current past the electrolyte. The efficiency of these Nernst lamps has been found to be extremely high, about 1·1 watts per candle-power; and it is estimated that in a vacuum the candle-power would be obtained with 0·7 to 0·8 watt. The life of such lamps as have been tried has not been very long. If it be true that electrolysis is taking place in the incandescent oxide, we should expect that the ions would accumulate at the ends of the rod; and if such were the case, it would not be favourable to the longevity of the lamp.

The Treatment of Battery Slimes.—An electrolytic process is now being worked in South Africa by the Crown Reef Gold Mining Company, for treating battery slimes, and thus removing gold which would otherwise be lost. The process seems to be working very successfully, if we accept the data given by J. R. Williams in the *Transactions* of the Chemical and Metallurgical Society of South Africa, 1897, July, pages 14 to 18. In this paper the results of two months' working are given, during which 6,640 tons of slime were treated with an assay value of 5·82 dwt., yielding 1,067 ozs. of gold with an actual extraction of 60·48 per cent., and giving a profit of £3,058. The cost of treatment per ton is 3s. 9·05d., in which we note that 0·40d. is included for electric light, and 2·75d. for power. After successive periods of treatment of three hours each, by electrolytic precipitation, a solution containing 2 drw. 12 grains of gold per ton assayed 1 dwt. 4 grains, 20, 12, 8, 4, 2 and 0·5 grains; whilst, after 24 hours, only a trace of gold was left.

Society of Arts.—On Wednesday evening Prof. S. P. Thompson read a paper before this society on "Telegraphy Across Space."

Telegraphing Without Wires.—The system of "telegraphing without wires," that is without *direct* wires between the two stations to be in telegraphic communication, recently suggested and experimented upon with so much success by Mr. Preece, Engineer-in-chief to the Post Office, has just been successfully applied to permanently establish telegraphic communication for the War Office between Lavernock Fort and the fort on the Flat Holm (in the Bristol Channel), a distance of 3¾ miles. On the mainland opposite the island, an ordinary pole line, three-quarters of a mile long, with a heavy copper wire, has been erected; the ends of the circuit terminates in the sea. On the island there is a similar line established, about half-a-mile long. The transmitting apparatus (on each line) consists of a contact breaker worked by a small dynamo, running at 3,000 revolutions per minute, and giving 250 makes and breaks per second, corresponding to the middle C note; the intermittent current is given by 10 Obach dry cells. An ordinary Morse key interrupts the circuit, and the receiving apparatus is an ordinary telephone receiver. The installation has been carried out under the direction of Mr. Gavey, Assistant Engineer-in-chief to the Post Office, assisted by Mr. Taylor. It has been found impracticable to maintain communication between the two forts by means of a cable, as the latter was continually broken by the anchors of the shipping.

Riveting by Electricity.—On Wednesday, before the Institution of Naval Architects in London, a paper on this subject was read by Mr. Holmes (secretary) for the author, Herr F. von Kodolitsch. The experiments of the author had extended over two years, and he had succeeded in bringing out a type of riveting machine quite capable of superseding the two systems already existing, namely, hydraulic and pneumatic riveting. There was no difference in the quality of the work done, but the quantity by the electric system was considerably superior. The machine he was describing closed 1,200 rivets in a day of 10 hours, when operated by three men and a boy. Specimens of the work done were exhibited. Mr. Hammond called attention to the fact that to use the electric riveter it was necessary first of all to lay down all the requisite electric plant. Mr. A. Denny stated that with the usual day and hydraulic machinery from 1,000 to 1,100 rivets could be closed, and he knew of one gang, where everything was arranged, which closed 1,500 rivets in the day. He thought that the use of electricity was bound to be economically applied in the building of ships at no distant date. Mr. C. Dutton thought the machine described by the author was not so portable as had been claimed. Our readers will remember that in the ELECTRICAL REVIEW for October 30th, 1896, we described and illustrated several applications of Herr Kodolitsch's universal electric drill in the arsenal of the Austrian Lloyd's Steam Navigation Company.

Hull Electrical Exhibition, 1898.—We have received a prospectus giving full details of the Electrical and Industrial Exhibition, which it is proposed to hold from May 19th to June 4th, at the Assembly Rooms and Lecture Hall, Hull. The principal objects of the exhibition are those connected with the electrical development in lighting, transmission of power, telephones, and the economical application of electrical energy to practical work, and in view of the extension of the municipal electricity undertaking, the present is considered an opportune moment for such an exhibition. Diplomas of honour, and gold, silver and bronze medals, will be awarded to deserving exhibits, and for this purpose a number of well-known gentlemen have consented to act as jurors and referees. These include Sir Frederick Bramwell, Sir Douglas Galton, Prof. Fleming, Prof. Ayrton, and Messrs. C. Bright, H. Graham Harris, W. P. J. Fawcus, S. V. Clirehugh, W. C. Johnson, Shelford Bidwell, E. H. Crapper, S. H. Valentine, and Mr. A. S. Barnard, the Hull Corporation electrical engineer. Early applications for space should be made to Mr. Joseph Davis, manager, 3, Assembly Rooms, Hull.

Marriage.—By last mail we learn that Mr. W. Elsdon-Dew, electrical engineer, Pilgrim's Rest, Transvaal, was, on February 26th, married to Miss Jessie H. G. Rankin, eldest daughter of John Rankin, Esq., Australia.

Magnetism and Diamagnetism.—At the Royal Institution on Thursday last week, Prof. J. A. Fleming gave the fourth lecture of his course on "Recent Researches in Magnetism and Diamagnetism." Resuming the study of the properties of diamagnetic bodies, the lecturer showed, says the *Times* report, two experiments illustrating some of the remarkable properties of bismuth. Righi found that a bismuth wire placed in a magnetic field, and transversely magnetised, suffered a great increase in its electrical resistance, and Profs. Dewar and Fleming proved this effect to be enormously augmented at very low temperatures. Another peculiarity of bismuth was its marked exhibition of the "Hall effect." If an electric current was sent through a bismuth plate which was transversely magnetised, an electromotive force was brought into existence at right angles to the direction of the current and the magnetic field, and showed itself by causing a displacement in the equipotential lines. This effect occurred to some extent in all metals, but was several thousand times greater in bismuth than in any other case. Passing on to consider the relations between magnetism and heat, the lecturer first performed an experiment which rendered evident the effect of change of temperature on permanent magnets. A permanent steel magnet suddenly heated first lost a certain portion of its magnetic strength, and then reached a more stable condition, in which it was said to be "aged," a result which could also be attained by plunging the magnet into liquid air. After the permanent state had been reached, the effects of change of temperature became more regular, and recent research had demonstrated that certain kinds of steel could be produced which had no temperature-change of magnetic strength after ageing. Prof. Fleming then exhibited a number of experiments to show that the ferromagnetic bodies, iron, nickel and cobalt, all changed at a certain temperature, varying for each, into the paramagnetic state, in which they were practically non-magnetic. This change took place in nickel at about 340° C., and a pretty experiment was shown, in which a star-shaped disc of nickel, balanced on a pivot in front of a magnet, was set in rotation merely by being heated at one place. The disc in this way was rendered magnetically lop-sided, and the magnet continually pulled it round into a fresh position. In conclusion, some interesting experiments were performed to prove that the temperature at which this magnetic transformation took place was also marked by the occurrence of several other important physical changes.

Large Continuous Current Dynamos.—The most powerful continuous current dynamo now known is that constructed by the General Electric Company at Schenectady for the Louisville Tramways Company. This dynamo, which has 22 poles, will produce normally 2,400 kilowatts, at an angular speed of 75 revolutions per minute. In cases of emergency its available power can be augmented one-third, and raised to 3,200 kilowatts. The external diameter of the crown bearing the field magnets is 5·7 metres; the breadth of this crown is 1·25 metres. The diameter of the armature is 3·8 metres; the diameter of the commutator is 2·9 metres; that of the shaft 58 centimetres; the length of the armature is 1·5 metres; that of the commutator, 55 centimetres. The armature and its collector weigh 38 tons; the entire machine, 80 tons. Before this dynamo had been made, the most powerful type was that of 1,500 kilowatts, working the intra-mural railway of the Chicago Exhibition in 1893. Dynamos of this type have been installed at Philadelphia, Boston, and Chicago for the service of overhead tramways or railways. The tramway station at Brooklyn contains four, and two others are in course of installation. When the two latter are at work, the Brooklyn station will be next to that of the Niagara Falls, the most powerful electrical station in the whole world; but it will not long hold the record, as in two years there will be at New York a station of 70,000 kilowatts, supplying the whole tramway system of the town.

To our Readers.—As next Friday is Good Friday, our issue will be published on Thursday morning, and all matter for that number should reach this office a day earlier than usual. Advertisers, contributors, and correspondents, please note!

French Import Duties on Lead and Accumulators.—By an Act passed March 3rd, 1898, the import duties on lead, its rich ores and its various compounds, were modified or completed in accordance with the following table:—

Numbers.	——	General per 100 kg. in fr.	Tariff minimum per 100 kg. in fr.
239	Minimum	8.50	5.15
	Litharge and other oxides	8.75	5.30
225A	Salts of lead and chemical products with undenominated lead base	5 % *ad valorem* + 2.40 fr. per 100 kg.	5 % *ad valorem* + 2 fr. per 100 kg.
256	Acetate of lead ...	11 50	7.60
262	Carbonate of lead (white lead)	8 50	5.60
266	Chromate of lead ...	25.50	18 50
576	Pipes and all kinds of other work in lead ...	8.50	6.50
576A	Electric accumulators.	21 50	16 50

The Automobile Club of Great Britain.—This club intends, at Easter time, to make a tour on motor vehicles. The party will start from the club house on Thursday afternoon next, and journey through the southern counties, stopping at Guildford for the Thursday night, Winchester for the Good Friday night, Chichester for Saturday night. Worthing for Easter Sunday night, and Tunbridge Wells on Easter Monday night, and from thence returning to London. The carriages will in all cases be driven by amateurs. Fifteen owners of motor carriages have already notified their intention of joining the tour.

Obituary.—We regret to record the death of Mr. Stephen Alley, senior partner of the well-known firm of engineers, Messrs. Alley & Maclellan, of Glasgow. Mr. Alley's death occurred last week at his residence, Langside House, Glasgow.

A Coolgardie paper dated January 29th, records in very touching terms the death and funeral of Mr. Hubert Musgrove-Musgrove. By profession Mr. Musgrove was an electrical engineer, and was for some years representative in Australia of the Electrical Power Storage Company, but he was also an accomplished amateur violinist and a fluent linguist. Mr. Musgrove arrived in Western Australia a little over four years ago, and was well known and highly respected. He was only 37 years of age. Previous to going out to Australia, Mr. Musgrove carried on business in Glasgow for many years under the title of Norman & Son, and after converting the business into a limited company he became associated with the Electrical Power Storage Company. Latterly, however, Mr. Musgrove became interested in gold mining.

Burning or Barging of Refuse.—At a meeting of the Battersea Vestry last week, an important declaration was made on the subject of the disposal of refuse. For some time the Battersea Vestry endeavoured to destroy the parish garbage by destructors; but nine months ago this method was discontinued, and the refuse was consigned to Kent. Mr. West reported that the working of the new system was at first beset with considerable difficulties. There was, for instance, only one barge for conveying away the refuse, and a considerable quantity had still to be dealt with by the dust destructor. Notwithstanding this, however, the system had been a great success. It was estimated that, as compared with the cost of utilising the destructor, there would be a saving of £2,000 a year. Although only nine months had elapsed, and although the difficulties had been great, yet £1,600 had already been saved. He had no doubt that the estimate of £2,000 would be considerably exceeded.

Appointments.—Mr. Bates, of London, has been appointed electrical engineer to the Birkenhead Corporation by the Electrical Committee at £300 per annum.

The Co-operative Wholesale Society has appointed Mr. A. A. Blackburn, of Leeds, to the position of electrical engineer of their large works near Manchester.

The Electrical Installation at Oldham County Court.—In the House of Commons on Tuesday, Mr. Ascroft asked the First Commissioner of Works whether he was aware that local firms were not allowed to tender for the electrical installation recently put in the Oldham County Court offices; whether there was any rule which prohibited fully qualified firms tendering for such work, and whether he would consider the advisability of allowing all such firms in the future the opportunity of tendering for local work undertaken by the Board of Works. Mr. Akers-Douglas, in reply, said that there is no rule that prohibits qualified firms tendering for the work to which the question refers. In the present case the work had to be executed in a very short period of time for departmental reasons, and tenders were obtained from two well-qualified firms, who could be relied upon to do the work in the time required. Whenever circumstances permit, local firms will be invited to tender for works in charge of the Board.

Parliamentary Committee on Electrical Energy.—Yesterday (Thursday) Viscount Cross presided over the first meeting of the Joint Committee on Electrical Energy (generating station and supply) at the House of Lords, the members of the Committee being, besides the chairman, Earl Spencer, Lord Knutsford, Lord Monkswell, Lord Balcarres, Mr. Ashton, Mr. Kimber, and Sir Leonard Lyall. The points to be considered by the Committee we have already stated. The Committee sat in private, and decided to adjourn till April 21st, when Earl Morley and Sir Courtenay Boyle will be called as witnesses.

Lectures.—Mr. J. E. Stewart, manager of the Derby Electric Light Station, delivered a lecture on "Some of the Uses to which Electricity from the Corporation Supply can be Put," at Victoria Street Church Schoolroom, Derby, on Thursday last week.

Before the East of Scotland Engineering Association at Edinburgh on 22nd ult., Mr. R. W. Hogarth read a paper on "Recent Developments in Electrical Engineering." Electric traction and electric welding were dealt with.

The War Office and English Copper.—We must congratulate the War Office upon at last discovering that there is such a thing as English electrolytic copper. Up to the present the War Office have obtained their supplies from America, but we understand that four of the principal copper smelters in this country have been invited to send samples of their products to be tested by the War Office authorities.

London County Council Electricity Meter Tests.—On 29th ult. the L.C.C. finally approved of the revised rules and scales of fees for the testing of electricity meters and other services rendered by the Council under the Electric Lighting Acts and Orders.

Testing Accumulators.—As we go to press, Mr. Albert Campbell writes: "In the reply to my letter in your last issue your correspondent states that, when the voltage of a motor car battery has fallen from 50 to 45 volts, more current must be taken than at the start; but he does not assure us that this *can* be done in practice. His proposed test at constant watts does not, therefore, seem to correspond to anything possible in practical working."

Appointment Vacant.—The Dewsbury Corporation is wanting an electrical engineer (salary £250) to take charge of the electricity works. April 9th is the latest date for sending in applications to the town clerk.

Who Is It?—According to Wednesday's *Daily Telegraph*, an inmate of Spalding Workhouse Infirmary, who has just been removed to the workhouse at Docking, in Norfolk, has had a remarkable career. He was a son of a former Alderman of the City of London, who died worth £40,000. He was himself educated at Christchurch, and was a scholar and expert electrical engineer, but ultimately had to seek refuge in the infirmary at Spalding Workhouse.

Personal.—Mr. Lewis J. Steele, who was Mr. Gisbert Kapp's assistant at Messrs. Johnson & Phillips, and who has since acted as chief designer to them, is severing his connection with this firm after eight years, to take up the appointment of chief electrician to the well-known firm of Messrs. Veritys, Limited, at their works, Aston, Warwickshire.

CITY NOTES.

Another Mutual Improvement Company.

The prospectus of another Mutual Telephone Company, whose aim is to improve the telephone service of Manchester and other places, has been issued. It is frankly admitted that it will be necessary, before any new service can be started, to obtain a license from the Post Office; but the organisers of the company do not feel inclined to make this application till at least £80,000 has been subscribed. The prospectus seems to base its claim for public acceptance mainly on the grounds that the company will introduce important improvements, and that hundreds of public bodies have passed resolutions in favour of the company. The scale of charges suggested is curious, and worth noting. Non-shareholders, within a mile radius of the Manchester exchange, will pay £6 10s. for each telephone; holders of five shares, £5 15s.; and holders of 10 shares, £5 5s. It would be interesting to know how many shares are necessary to obtain a telephone for nothing; or following the sliding scale still further, at what number of shares does the company begin to pay the shareholder for having a telephone.

The Brockie-Pell Arc Lamp Company.

It cannot be denied that the results of the 17 months' working of this company have been unfortunate. We are not going to say that the directors have not had stupendous difficulties to contend with, and many of the troubles that have been experienced are not likely to occur again; but there have been unsatisfactory incidents disclosed in the short career of the company that are regrettable in the extreme. Considering that nothing had been done in the way of organising a factory when the company was formed, the prospectus ought to have been expressed in more moderate language. Salaries and directors' fees are items that do not seem to be quite in accordance with the period of trial and error through which the company has passed. However, the shareholders are well advised in adopting the report and putting their trust in the future.

Electric Supply Company of Western Australia.

The prospectus of this company, with a share capital of £100,000 in £1 shares, was brought before the public in the early part of this week. Some of the directors are well known in the electrical world, the chairman being Mr. Bennett Fitch, a director of the St. James's and Pall Mall Electric Lighting Company, and three directors are on the board of the British Insulated Wire Company. Much is made of the fact that the objects of the company are to take over from the Westralian Electric Lighting and Supply Company, Limited, the existing system of electric lighting now being worked in the town of Coolgardie, Western Australia. It must be always a satisfactory feature to potential shareholders to know that they are taking over an established undertaking "already earning profits," but naturally it is assumed that an established business which requires a share capital of £100,000 to purchase and to work must be something exceptional. We will examine the established business as far as we can in a moment. In the meantime we would note that, though prosperity in Western Australia is a matter at which all right thinking men should rejoice, we are obtuse enough to suggest that the increase in the revenue of the colony which is made much of by the prospectus has very little connection with the electric lighting of Coolgardie. Now let us go a little closer into the business and concessions which are to be acquired by this company. Coolgardie seems to be very much of a mushroom town, and owes its sudden rise to the proximity of the Western Australian gold mines. It is only five years since the first settlement was made, but in November, 1897, the population of Coolgardie and district is given at 20,000. Truly a remarkable increase! The company acquires what is, no doubt, valuable freehold land in one of the main central streets of Coolgardie, on which works are built and electrical machinery erected. The concessions acquired include the sole right to supply electricity in Coolgardie for 25 years, and rights to carry electric cables to the gold mines. No doubt those are valuable privileges, and are worth something. That is not all, however, for the electric lighting business which is to be acquired has been working since July 10th, 1897, and the gross receipts are stated to be equivalent to £9,500 per annum. For these various items the sum of £70,000 is to be paid, which, at least, shows that the vendors have confidence in the value of the business.

No details are given of the size of the electric lighting plant, or of the original cost, and, indeed, there is a marked absence of information as to the value of the assets to be acquired for £70,000. It argues a large measure of faith in the public to propose a company, with a capital of £100,000, with such ill-defined assets and property as shown in the prospectus of the Electric Supply of Western Australia.

Metropolitan Electric Supply Company, Limited.

Sir Eyre M. Shaw, K.C.B. (chairman), presided on Tuesday morning over the eleventh ordinary general meeting of the above company, held at Winchester House.

The Chairman said: In rising to move the adoption of the report and accounts, I desire as usual to offer a few remarks, though I think that these accounts are given in sufficient detail to obviate the necessity of detaining you very long in explaining them. Dealing first with the capital accounts as shown in Statements 1 and 2, you will see that the only capital raised during the year has been £62,500, the balance of the £125,000 new capital issued in 1896, and which from June 30th, 1897, became part of the ordinary share capital of the company. Statement No. 3 deals principally with the expenditure on capital account amounting during the year to £93,795 16s. 10d., with a grand total of £850,831 19s. 9d., and a balance of £29,597 18s. 10s., which is now practically expended, a matter to which I shall have to refer later on. The principal items of expenditure have as usual been the continually extending mains, which account for £38,869 12s. 5d., and the expenditure on transformers and meters for the supply of the increasing list of our customers, who now number about 6,000. These two items, transformers and meters, with their connections, absorb £15,823 4s. 2d., making with the mains an expenditure of £54,692 16s. 7d., or considerably more than half of the total sum expended during the year. The remaining items of any importance are lands, £12,801 8s. 5d. being the cost of purchase of our new site for generating works at Willesden; buildings, £9,445 18s. 11d., represented by extensions at Amberly Road, Sardinia Street, and Manchester Square; and machinery, £15,367 16s. 1d., which has been expended on account of equipment of those extensions, an equipment which when completed will materially increase our facilities for supplying our customers. We will now turn to the revenue account, which shows the result and cost of our working during the year, and from this account it will be seen that the income from current is steadily increasing, giving a total revenue of £138,267 14s. 6d., as against £116,459 4s., an increase of about £22,000, or 19 per cent. The expenditure to earn this larger income also shows, as will be expected, an increase, but not to so great an extent, being for cost of generation £58,604, against £52,619, an increase of £5,985, or 11½ per cent., principally due to the increased consumption of coal and oil, and a total revenue expenditure of £79,546, against £70,267 in 1896, being a total increase of £9,279, or 13 per cent. as compared with 19 per cent. increased income, as already stated. The increases shown in distribution have arisen from the extensions of mains and developments of the system of low pressure distribution, while the growth of management expenses has been caused partly by necessary additions to the company's staff, in order to cope with the rapidly increasing work, and partly by the larger amount of the directors' fees. With regard to these fees, I think it right to remind you that some years ago the board agreed among themselves to take a very considerably reduced remuneration from that allowed by the articles of association, until the company should be earning substantial dividends, and that even at the present time the full amount allowed by the articles is not drawn. As I informed you at our recent extraordinary general meeting, the number of new customers continues at even greater rate of increase than at any former period in our history, and there are many indications tending to point to a still more rapid growth in the immediate future. Believing as we do that to be truly a success the electric light must be regarded less as a luxury and more of a necessity, we have, after the most careful consideration, decided to make substantial reductions in our rates of charge from the commencement of the present year, which, though they may affect our revenue to some extent for a little time, will, we feel convinced, in the long run amply justify our policy by the extended business which it will bring to us. This continual increase, while it is extremely satisfactory as pointing to the continued growth of our business, involves us in the obligation of making adequate provision for our future requirements. I have already informed you of the reasons which led us to procure a most advantageous site at Willesden on which it is intended to erect large generating works, the existence of which will relieve us from any anxiety for many years to come. By gradually extending these works as occasion may arise—and there is ample space at our disposal for doing this—we can place no limit to the amount of power which can be produced. Intimately connected with these extensions as affecting our cost of manufacture and distribution, which it is our earnest desire to reduce to their lowest possible figures, is the development which we have now in progress for changing our system of supply in those portions of our areas where the lamp density warrants the laying down of low pressure mains, and we have every reason to hope that a large portion of this work will have been completed before the close of the present year. The mention of these new works leads me naturally to the question of new capital. Before, however, dealing with this matter, I propose to lay before you, as briefly as possible, the result of our recent negotiations with the holders of the founder shares. You will remember that, at the last general meeting, an undertaking was given by me that efforts would be made to come to an arrangement with the founders for the extinguishment of their rights. We accordingly gave the subject our most careful consideration, and after taking the opinion of our financial and legal advisers, we prepared a scheme which had, as its basis, an allotment of 140 new ordinary shares at par in exchange for each founder share. The agreement embodying these proposals was sent to the founders, together with a circular, in which the views of the directors were fully explained. The meeting which was held to consider these proposals resulted in the appointment of a committee of the founders to negotiate with the directors, and the result of the deliberations of this committee is embodied in the following letter:—"The committee appointed by the holders of founder shares to report on the offer made by the board has very carefully and fully considered the directors' proposal, and has unanimously determined that the offer is inadequate, and should be declined. The committee is confirmed in this opinion by comparing the terms with those accorded to founder shareholders in other leading electric supply companies. The committee has ascertained that holders of a considerable number of founder shares prefer to remain as they are, and will not entertain any offer less favourable than the allotment of 300 ordinary shares at par." To this letter the board replied that this offer was not one which they could consider themselves justified in recommending the ordinary shareholders to accept. As the result of another attempt to effect an arrangement, we have lately received a further letter from the founders' committee suggesting that the founders might accept an allotment of 250 ordinary shares, but the directors are still of opinion that these terms are far too high, and that the ordinary shareholders would be unwise to accept even this reduced basis of settlement. We very greatly regret the failure of these negotiations, for it would manifestly have been to the best interests of the company as a whole that they should have succeeded. In our circular to the founders we indicated that in our opinion the ordinary shareholders could not be asked to pay a premium on any issue of new shares, seeing that the effect of this premium would be, as we think, unreasonably to improve the position of the holders of the founders' shares at the expense of the ordinary shares. To this opinion we adhere, and unless within a very short time we are able to come to terms with the founders we shall probably issue a large portion of the new capital to the existing shareholders at par, though it is our intention to postpone dividends on these shares until the new works can fairly be expected to be earning their proper proportion of revenue. We have been informed that at least one of the founders intends to attempt to restrain us by legal means from adopting this course on the ground that by doing so we are prejudicing the rights of the founders. Well, gentlemen, much as we regret the possibility of this course being taken, we think it best that once and for all the discretion of the board in matters of this kind should be clearly defined. One other point connected with this subject, and I have done. It is best raised by reading to you from a letter we have received from Mr. Orrell, in which he says:—"Permit me to point out to the directors that the item 'Premiums on debenture stock and new shares,' &c., £35,429 9s. 7d. in account No. 3, capital account, is clearly not an item of capital account, but of revenue, and is a net profit, and should be treated as such, and be placed in Account No. 4, which, after deducting 10 per cent, in accordance with Art. 132 of the company's articles of association, is available for dividend, and should be paid to the shareholders. I hereby give notice to the directors that I object most strongly to this sum of £35,429 9s. 7d., less 10 per cent. being placed to reserve funds without the consent of three-fifths of the holders of the founders' shares being obtained, and it is my present intention of moving at the general meeting that the accounts be rejected and amended in manner above stated, and the full dividend paid. It is with very great regret that I feel compelled to take this step, which is most distasteful to me, but there is no other alternative, after the expression of the views of the directors contained in their letter of January 20th, 1898, with regard to the rights of the founders' shares, and the expressed intention of the directors to issue to the shareholders *pro rata* a large amount of ordinary shares at par, which I am advised by Mr. Charles Jenkins, Q.C., would be a breach of trust on their part. What security have the founders' shareholders that if the net profits fall short at any future time the directors will not appropriate this £35,429 9s. 7d., to augment the dividends on the ordinary shares? I trust the directors will give the founders some assurance that in issuing the new capital they will obtain the best price which can reasonably be obtained for the new shares, and I feel sure that the consent of three-fifths of the holders of the founders' shares will be obtained to place the whole of the premiums to a reserve fund for the benefit of the company; but in this matter I speak for myself only." I think you will agree with me, gentlemen, that Mr. Orrell has succeeded better than I could ever have ventured to do in justifying the policy of the board, by pushing to its extreme limit the consequences of issuing shares at a premium. He asks us to place the whole of the premiums already received (less 10 per cent.) to revenue account, and a little further on he requests us to give the founders an assurance that the board will obtain the best price they can get for the new shares, feeling sure (though he only speaks for himself) that the founders will agree to the placing of such future premiums to reserve. With regard to the sum of £35,000, this has not been treated, and in our opinion ought not to be treated, as a revenue profit for any dividend purpose whatever, and the same remark applies to any future premiums. If Mr. Orrell's contention be valid, that it is the duty of the board to treat premiums as profits divisible as dividend, after deduction of 10 per cent. as reserve, it will be seen that, the dividends being immediately forced up above the 7 per cent. limit, the founders will obtain a very large proportion of such premiums at once, while the security of the ordinary capital in respect to its future repayment will be proportionately diminished. Of course, whatever Mr. Orrell may say, the holders of founders' shares cannot treat premiums both as revenue profits, and as reserve as well, but it is clear that in either case the issue of shares at a premium will be more to their benefit than to that of the ordinary shareholders. With these remarks, gentlemen, I beg to move the following resolution:—"That the report and accounts for the year ended December 31st, 1897, presented to this meeting be and are hereby approved and adopted, and that in addition to the interim dividend of 5s. per share paid on October 15th, 1897, a further dividend of 7s. per share on the whole of the original ordinary shares, and of 6s. per share on the new shares of the company be and the same is hereby declared, such dividends to be payable on March 30th, 1898, to all holders on the company's registers on March 19th, 1898."

Admiral Sir John Hay seconded the motion.

Considerable discussion followed, and several speakers expressed the hope that every effort would be made to arrange the matter amicably with the founders.

Mr. Orrell moved and Mr. Baldwin seconded an amendment that the report be not adopted; but the Chairman pointed out that was simply a negative to the motion for the adoption of the report.

The report was carried by a large majority.

Willans & Robinson.

Mr. M. Robinson presided on Wednesday afternoon at the ordinary general meeting of the shareholders of the above-named company held at the City Terminus Hotel, Cannon Street. After the secretary had read the notice convening the meeting, the directors' report and accounts were taken as read.

The Chairman moved the adoption of the report and statement of accounts, and in so doing said he thought he might safely state that, in view of the many difficulties they worked under last year, the accounts were equally satisfactory for the past and promising for the future. If the great strike passed them by, so far as concerned the relations between the company and their own workpeople, which were never better, yet many firms upon whom they depended for assistance in the form either of stores or of finished engine parts, or of tools for their works, had their shops brought wholly or partly to a stand. These labour troubles had reflected heavily upon the company, causing some of their capital to remain idle, and keeping down their output of engines. Tools ordered over a year ago were still undelivered, and thus a part of their capital had been idle for a year, drawing interest while producing no engines. They were, however, gradually surmounting the many troubles entailed by the strike, and he had no doubt that they would agree with him that the balance-sheet now submitted was even more satisfactory, as the outcome of a difficult time, than if it represented a period when all had gone well with them. The moderate increase in the dividend now recommended might have been paid before, but the fixed policy of the directors was to make sure of every step before taking it. Depreciation had increased by over £1,100 for the half-year, and this item they must expect to increase further, as their new works were gradually completed. To the debenture sinking fund they had carried the usual contribution of £2,000, and to the reserve fund proper the increased sum of £1,500, making no less than £6,500 reserved out of the profits during the 12 months. The prospects of work before them were all that they could desire. It was no longer doubtful that electric traction was about to receive a great development in this country, and in this the Willans engine would play a leading part. Already an engine to indicate up to 1,500 horse-power was under construction for traction work, and they had been called upon to prepare designs for an engine of 2,500 horse-power. The size of the engines they made had increased to a startling extent. This development threatened to go beyond the utmost anticipation of the directors, and to involve additions to their plant beyond what the present capital provided. The question, however, was not immediate, but it was well to mention it. Fortunately at Rugby they were in a position where extensions, when necessary, could be made rapidly and economically. They hoped that the relations between the company and their workmen would in the future be even better than they had been in the past, for in pursuance of a long-desired scheme for binding their old hands more closely to them, they had instituted, since the close of the strike, a system of long-service bonuses, which they thought would give their men a strong inducement to remain with them. He was glad to say that this offer had been received with much satisfaction by their men. Having called attention to certain items in the balance-sheet and loss account, he said he might anticipate a question, which would otherwise doubtless be asked, as to the success of their recent small issue of shares—3,000 preference and 3,000 ordinary shares were to be issued, but owing to the effect of fractional holdings, only 2,838 preference and 2,854 ordinary shares were provisionally allotted, subject, that was, to acceptance. The numbers accepted were 2,447 preference and 2,296 ordinary, and the balance was applied for 10 times over by their own shareholders alone.

Mr. A. Holland seconded the motion, and observed that the shareholders had abundant reason for gratification, for the business had grown very rapidly.

The motion was carried, and a further resolution to pay a dividend at the rate of 8 per cent. on the ordinary shares was agreed to.

Mr. M. H. Robinson and Capt. Sankey, the retiring directors, were re-elected.

Brockie-Pell Arc Lamp, Limited.

The directors in their report state that they regret very much that the result shown by the accounts is not more satisfactory. This is due principally to the long period taken in equipping the works with the various machines, and making the numerous patterns and special tools required in the manufacture of the lamps. The first 100 lamps, made entirely at the company's factory in Tabernacle Street, were not completed until the end of July last, so that the business has only been in full swing for a period of from five to six months. As showing the estimation in which the company's lamp is held, it will be satisfactory to shareholders to know that the whole of these 100 lamps were erected in the principal streets of the city of Glasgow, to replace those of other makers. Amongst the numerous customers of the company during the period under review, may be mentioned several departments of H.M.'s Government, corporations, vestries, exhibitions, railways, &c. The orders received from month to month have shown a steady increase. The total number of "Brockie-Pell" lamps supplied to the public in 1897 exceeded that of 1896, thus showing continued progress. In order to save inconvenience to the public during the time the factory was being equipped, the directors allowed the late makers to continue the manufacture of the lamps for some months, and to execute the orders they had received upon payment of a royalty to the company. The directors also agreed to take over from them the stock of lamps left upon their hands after such orders had been provided for. It will thus be seen that the company has not had the benefit of any manufacturing profit on the greater part of the business transacted since its formation. The engineering strike, which lasted about six months, caused a considerable amount of trouble and loss to the company. Great difficulty was experienced in obtaining delivery of material required by the factory, and orders were kept back by customers in consequence of their finding it impossible to procure the necessary machinery for operating the lamps. All the preliminary expenses have been written off, and also a portion of the outlay on furniture and tools. After lengthy negotiations the directors signed a contract in October last for the sale of the French and Belgian patents for £3,000 in cash, and shares in a company to be formed. £500 has been received on account. Mr. Brockie has taken out several new patents in 1897 for further improvements in arc lamps and accessories. These belong to the company, and it is anticipated that they will prove of value, and create an extension of business. The company has also a considerable interest in a patent granted to Mr. Brockie for an automatic lathe, worked on an entirely new principle, which will probably prove a valuable asset in course of time.

Lord Suffield presided over a crowded meeting of shareholders of this company, held on Tuesday at Winchester House. The chairman went through the various items of the report which is given above. He said it was not until the end of 1896 that they were able to enter the premises they had secured in Tabernacle Street. In the meantime, however, Mr. Brockie had not been idle, and had been able to obtain machinery from the Continent for the purpose of carrying on the work. It was not, however, till March of 1897 that work was commenced upon the various special tools they required. With a view to saving time, a considerable number of those tools were made to their design by others; but notwithstanding this help, week after week passed, and they appeared to get no nearer to the desired end. They knew that Mr. Brockie was doing his utmost, and considering the enormous amount of detailed work that required his personal supervision, there was no reason to be dissatisfied with the length of time taken to bring the factory into working order. When the first 100 lamps were completed by their own men, namely, at the end of July last, that left practically only five or six months in which to make any manufacturing profit. Paragraph No. 7 showed continued progress in the sales of the lamps. Of course, they had not had the full benefit of the increased sales, and had to be satisfied with receiving royalties only. The new patents granted to Mr. Brockie last year included some important improvements in the construction of arc lamps and accessories in connection with them, which they fully believed would add to their business, and practically extend the time of the monopoly. Before putting the resolution, they would no doubt like to hear something of the prospects of the company for the current year, and he had much pleasure in saying that the volume of business at present in hand was very satisfactory. The value of unexecuted orders amounts to between £8,0 0 and £9,000, although they have not yet reached the end of the first quarter of the year.

Sir F. D. Dixon-Hartland seconded the motion. In doing so he said he could not but feel that the accounts were very disappointing, but at any rate they were honest accounts, showing the exact state of the facts. There had been no attempt to keep anything back. He did not think that anybody who was not a director of the company could have had the slightest idea of the work, the anxiety, the trouble that had been caused to the board. They had, to a certain extent, been environed by difficulties which were unforeseen at the time the company was brought out, but he believed that at the present moment they were on the road to success. They took over a business which had been carried on by Messrs. Johnson & Phillips. They were informed that the works would take about four or five months, but in reality it was nearly 12 months before they were got into working order. They had had to make all the parts, and all the tools for making the parts, and that took a considerable time. Another difficulty was, that Messrs. Johnson & Phillips knew that they had got a good thing, and were most anxious not to give it up. At first they said that Mr. Brockie and Mr. Pell had no right to sell the patents to anybody else, that they had a legal right to keep the patents as long as they existed, and that all Mr. Brockie and Mr. Pell could do was to give a concurrent right to this company. Thanks to the energy of the solicitor, the directors were able to get over those difficulties, and at last Messrs. Johnson & Phillips gave up that contention. Then it was found that they were continuing to manufacture the lamp, and for the sake of peace and quietness an undertaking was taken from them that they would make no more of the lamps. The company bought the whole of their stock of lamps. Of course, all this was not done without an immense amount of thought and labour, and he was sorry to say that they had now moved for an injunction against Messrs. Johnson & Phillips for infringing the patents. In a letter which they had written, Messrs. Johnson and Phillips said that there was only a 2 per cent. profit on the manufacture of the lamps, but if that were so would they fight so hard, or would they have paid 7½ per cent. upon the gross list price of the lamps? The board had put an end to dual management, and now had one responsible managing director, who would take sole charge of the work so far as the commercial part was concerned. He had very little doubt that before long there would be good profits for the shareholders. It had been suggested that the directors had helped to rig the market, but he did not believe that one of them had bought or sold a single share. They had nothing whatever to do with the market. Their object was to make the company a success, and whether the shares were up or down it was not for them to consider.

Mr. Clement thought the company was floated on conditions that were entirely unjustifiable. No doubt there was good reason in the delays that had arisen. He asked whether they had guarantees for payment of the Belgian rights?

Mr. Skipworth: So far as he could see, their assets were not worth 60 pence, and that was all they had to show for their £60,000. How was it that they had only got £500 for the Belgian and French patents? He moved as an amendment: "That the directors' report be received, but that the same be not adopted, pending the report of a committee of investigation to be now appointed by the shareholders."

Mr. Waugh said he had confidence in the directors, who held nearly two-thirds of the shares, and he did not see why a committee should be appointed.

Sir F. D. Dixon-Hartland, in reply, said the whole of the amount on the 5,000 shares had been called up, but the time was not yet up for payment. With regard to money to go on with, there was about £1,000 to come from the shares. Then £3,000 was expected in July for the patents. There were also book debts, and the company was not going to manufacture £8,000 or £9,000 worth of lamps without getting something for them. The directors, therefore, hoped that with a little borrowing from the bankers they would be able to get through until such time as greater profits could be made. The patents were examined by an eminent firm of patents agents, and therefore it must be presumed that they were perfectly good. The factory was leased for 21 years. With regard to the foreign patents, some gentlemen approached the directors and said: "We are prepared to give you £3,500 in cash for your patents for France and Belgium; we are then going to float a company for those countries, and then we shall give you one-fourth of the shares." The board were not going to be satisfied with the output for the last five months; they hoped to double and even quadruple it, and then the working expenses would drop in proportion, and there would be a chance of making profits. The directors were quite willing to draw only two-thirds of their fees until the company proved a success. If at the end of another 12 months, satisfactory results could not be shown, other men might be elected on the board.

Mr. Skipworth withdrew his amendment, and the motion for the adoption of the report was then agreed to.

The retiring director, Mr. H W. Maynard, was re-elected; the auditors, Messrs. Mellors, Basden & Co., were re-appointed, and the proceedings terminated with a vote of thanks to the chairman.

Direct Spanish Telegraph Company.

The Marquis of Tweeddale (chairman) presided over the ordinary general meeting of the shareholders of the above company, held at the offices, Winchester House, on Tuesday, and in moving the adoption of the report, said he must express the sincere regret of the directors, which he felt would be shared by everyone connected with the company, at the death of Mr. Ettinger. Turning to the accounts they would observe that the balance to the credit of revenue account was £12,975 6s. 4d., and after adding £5,000 to the reserve fund, the directors recommended that the balance be distributed as follows:—10 per cent. on the preference shares, and 4 per cent. on the ordinary shares, absorbing £5,486 4s. Half of the amount was distributed in October as an interim dividend. The traffic receipts showed a decrease of £2,927. With regard to that decrease, only £674 was applicable to the first half of the year of 1897, when the same rates as in 1896 were in force. The remainder of the decrease took place in the second half of the year, and no less than £1,974 was due to the reduction in the rates agreed to at the international telegraphic conference, and to the mode of counting words and figures agreed to at that time, which came into force on July 1st. Without that reduction, the traffic for the year was only £983 less, which would have been very satisfactory, considering the very exceptional traffic they enjoyed in 1896. The working expenses were £223 8s. 11d. in excess of the year 1896. The increase was on account of salaries, amounting to £204 2s. 11d. Their former chairman, Sir John Pender, alluded to that matter some years ago, and pointed out that it was absolutely necessary that some arrangement of the sort should be made if they expected to secure the services of good men. There was also a small increase of £39 for repairs and renewals of instruments and landlines. The company's cables, and the landlines in connection with them, have continued in excellent working order during the year. At the last general meeting he referred to the litigation connected with the Bilbao breakwater, and said that the case would be tried before the tribunal in Madrid in April. The decision, as they probably were aware, was adverse to the company. The decision and judgment was based on points of law, and it was final, and the directors had, therefore, transferred the balance of revenue, £2,489, to the reserve fund towards payment of the cost of removal. The directors, in the exercise of their judgment, had appointed Mr. F. Johnson to the board. He was an able man of business, and happily a good deal younger than some of them, and would therefore, he hoped, have a prosperous career in connection with the company. As they knew, the leading telegraphic companies thought it right to celebrate the Jubilee of the Queen by granting bonuses to their employés, and the board felt that it would not be fair to make any exception to the employés of that company, who were in no way inferior in zeal to the employés of other companies, and so the bonus was granted to them. It was equal to 10 per cent. on the annual salary of members of the permanent staff with five years' service, and 5 per cent. on the salaries of those with less service. The sum was not a very important one, and he was sure that it would act as a stimulus to the employés of the company. He might mention that since January 1st of that year, up to the present date, the traffic was in excess of the corresponding period. The receipts were not quite so large, but that was due to the reduction to which he had referred. They began the year, therefore, on the whole, very prosperously, and he trusted that prosperity would last.

Mr. J. D. Pender seconded the motion.

Mr. Stimpson suggested that the board might see their way to pay a larger dividend.

The Chairman said they wished the dividend might be larger, and now they had got rid of the Bilbao expense, he hoped the accounts would show better.

The report was adopted.

The Guildford Electricity Supply Company, Limited.

The directors in their annual report state that they are calling the ordinary general meeting for 1898 earlier than in previous years, in order to present to the shareholders the accounts for the year ending December 31st, 1897, as they are desirous that the company's financial year may in future coincide with the calendar year, which is the period for making up the annual accounts required to be furnished to the Board of Trade. The number of installations connected with the company's mains is increasing, and now amounts to 52.

The directors are well satisfied with the result of the first complete year's working, and are gratified to think that the stage of remunerative business has now been reached, the revenue account for the quarter ending December 31st, 1897, showing a profit of £67 6s.

The subscribed ordinary capital has now reached £7,670; but, as it has been decided to increase the plant and extend the mains at once, further subscriptions for ordinary shares, to be paid in full on allotment, are invited from the existing shareholders.

Shareholders are reminded that the ordinary shares are entitled to the first profits in each year to an extent sufficient to pay a dividend of 6 per cent. thereon, before the founders' shares receive anything. The ordinary shares take also three-fourths of any surplus profits over 6 per cent., the founders' shares being entitled to the remaining fourth. Also, that the company holds a provisional order, granted by the Board of Trade and confirmed by Act of Parliament (57 and 58 Vict., C. cxv.), for supplying electricity in the municipal Borough of Guildford, and that under this order the company has a practical monopoly in the town for 35 years from July, 1894.

The annual general meeting of the company was held last Thursday at Guildford. Dr. F. R. Russell, chairman, presided, and said as they met only so recently as three months ago, he had little to add to what he then told them of the progress of the company. During the last quarter of last year they made the very fair profit, considering the company had only been running a year, of £67. Of course, that did not make up a profit on the whole year in their favour, because in the first two quarters of the year there was a loss. The last quarter, however, paid very handsomely. The company had now reached the maximum expenditure, and they could double the number of lights without spending any more money, except in the way of coal. But it was absolutely necessary during this year that they should add to their plant, and also lay some extra cables, and they must during the year raise further capital to the extent of £3,000 or £4,000 at least, or even more if they could get it. Since that report £430 in new shares had been paid in. He concluded by moving the adoption of the report and balance sheet.

Mr. Wheeler seconded.

Mr. Money-Kent gave some figures respecting the accounts, the report and accounts being then passed.

Bournemouth and Poole Electricity Supply Company.

Lord Rathmore, who presided on Monday last at the statutory meeting of the Bournemouth and Poole Electricity Supply Company, held at Winchester House, stated that the company's liability to the vendor company in respect of the purchase price had been discharged, and the purchase completed. An application had been made to the Stock Exchange for a special settlement and quotation, and the directors were daily expecting a notification that the same had been granted.

Evered & Co., Limited.

The report and balance-sheet shows, after providing for debenture interest, amounting to £2,416 13s. 4d., a net profit of £25,146 19s. 8d., making, with £7,288 11s. brought forward from 1896, the sum of £32,453 10s. 8d. to be dealt with. An interim dividend at the rate of 7½ per cent. per annum to June 30th, 1897, has been paid, absorbing £6,402 18s., and the directors propose to pay a dividend at the rate of 7½ per cent. per annum for the remaining six months, which will absorb £6,402 18s., and to pay a bonus of 2½ per cent. per annum for the year, £4,268 12s. The directors state that there has been an increased amount of business done, which they deem very satisfactory. This year the full amount of paid-up capital ranks for dividend. Further provision for increased trade has been made in the way of additional buildings at both works.

Mr. A. H. Griffiths has resigned his position as managing director in Birmingham, and Mr. R. B. Evered, the chairman of the board has undertaken the sole managing directorship, assisted in London by Mr. G. J. Evered, and in Birmingham by Mr. R. G. Evered.

British Electric Traction Company, Limited.

The directors in their report for the period from October 26th, 1896, to December 31st last, state that the company was registered in October, 1896, and 20,000 of the 30,000 ordinary shares offered for subscription were allotted. The subsequent issue of the remaining 10,000 ordinary shares produced a net premium after payment of expenses of £1,218, which amount has been applied in reduction of preliminary expenses account. Since the closing of the books an issue has been made of 10,000 6 per cent. cumulative preference shares of £10 each, at a premium of £2 10s. per share. The proceeds of this issue will be brought into the next account. The gross profits amount to £14,422, and after deducting the proportion of general expenses chargeable to revenue, and also the expenses incurred in connection with schemes not proceeded with, there remains a net profit of £9,804, which the directors propose should be carried forward to next account. Arrangements for the adoption of electric traction at the following among other places are in various stages of progress:—Coatbridge and Airdrie, Cork, Crewe, Dudley, Stourbridge and district, Gateshead-on-Tyne, Hartlepool, Lake District, Kinver, North Shields, Tynemouth and district, North Staffordshire, Oldham, Ashton, and Hyde, Kidderminster and Stourport, Middleton and district, Paisley and district, Potteries district, South Staffordshire, Swansea, Wolverhampton and district. Provisional arrangements have also been made and negotiations are pending in regard to a number of other places; but it would be premature, or inexpedient, to refer to them in this report. In some of the above cases agreements have been made for the purchase, or leasing, of existing tramway undertakings, while for other undertakings Parliamentary powers, or orders under the Light Railways Act, have been secured or applied for. In some instances the company has acquired the majority of the shares of existing tramway companies, and controls the business of such companies with a view to the adoption by them of electric traction. In a few cases the arrangements have been made in co-operation with other parties. With regard to South Staffordshire, the existing electric tramways are being worked by the company, and are a source of income. Contracts have been placed with responsible parties for the work of construction, and electrical equipment at Dudley, Stourbridge, Hartlepool, Kidderminster, and Stourport, North Staffordshire, Oldham, Ashton and Hyde, and Potteries, and the work is being proceeded with.

The Direct United States Cable Company, Limited.—The board have resolved upon the payment of an interim dividend of 3s. per share, free of income-tax, being at the rate of 3 per cent. per annum, for the quarter ending March 31st, 1898; such dividend to be payable on and after April 26th next.

Globe Telegraph and Trust, Limited.—An interim dividend of 2s. 6d. per share has been announced.

TRAFFIC RECEIPTS.

The Bristol Tramways and Carriage Company, Limited.—The receipts for the week ending March 25th, 1898, were £2,379 14s. 7d.; corresponding period, 1897, £2,207 19s. 5d.; increase, £171 15s. 2d.

The City and South London Railway Company.—The receipts for the week ending March 27th, 1898, were £1,066; week ending March 28th, 1897, £974; increase, £92; total receipts for half-year, 1898, £13,891; corresponding period, 1897, £13,791; increase, £100.

The Dover Corporation Electric Tramways.—The receipts for the week ending March 26th, 1898, £111 9s. 8d.; total receipts to March 26th, 1898, £1,277 18s. 7d.

The Dublin Southern District (Electric) Tramways Company.—The receipts for week ending Friday, March 25th, 1898, were £414 11s. 1d.; corresponding week last year, £476 19s. 10d.; decrease, £62 8s. 9d.; passengers carried, 69,266; corresponding week last year, 72,768; aggregate to date, £4,793 9s. 0d.; aggregate to date last year, £5,146 13s. 8d.; decrease to date, £353 4s. 8d.; mileage open, 8 miles. Cars, 1898, 211; 1897, 278. Miles, 1898, 18,979; 1897, 19,865.

The Liverpool Overhead Railway Company.—The receipts for the week ending March 27th, 1898, amounted to £1,303; corresponding week last year, £1,336; decrease, £33.

The Western and Brazilian Telegraph Company, Limited.—The receipts for the week ending March 25th, 1898, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £2,622.

THE NORTHERN SOCIETY OF ELECTRICAL ENGINEERS.

The Practical Operation of Multiphase Currents. By T. Hawkins, Member. March 14th, 1898.

(*Continued from page 422.*)

In a power installation, the generator is the part which is usually well protected, and gets the best attention. If a continuous current machine is used, the brushes will, at intervals, require to be adjusted and renewed, and the commutator trued up and kept clean; still there is always a skilled attendant at hand to keep the machine in order. It is, however, the motors, scattered in many instances over a considerable area, which have often the greater strain and harder work to do, and yet have less attention where the three-phase system to my mind has the advantage, especially where motors are only required to run at one constant speed.

As regards the line, a saving of copper is effected by using the three-phase instead of the continuous current system, but there must be three wires if the former be used, which brings the cost of the distribution on a low pressure system to about the same.

At the works of the General Electric Company, Limited, at Manchester, there is a three-phase power plant. The generator has an output of 100 H.P. at a pressure of 190 volts, and runs at 450 revolutions per minute, giving 45 cycles.

The following is a list of the motors:—

No.	H.P.	Speed.	Geared to.	Kind of gearing.	Starting device.
1	24	910	Shafting	Belt	Liquid resistance in stator.
1	18	910	Shafting	Belt	"
1	9	910	Shafting	Belt	None.
1	3½	910	Boring machine	Belt	"
2	3½	1,360	Shafting	Belt	"
1	3	1,360	7 ft. radial drill	Worm gear	"
1	2	Variable	Lathe	Belt	Resistance in rotor.

The 24 and 18 H.P. motors are not working on more than ¾ load. Each motor drives a 120 feet length of main shafting at 300 revolutions per minute, the main shaft being loaded along its entire length by high speed lathes and other machinery. The other belted motors drive shafting in the erecting shop, and are loaded nearly to their rated capacity.

In addition to the above, there are three motors, 6 H.P., 4½ H.P., and 1 H.P., used on a 5-ton 3-motor crane. The reduction of speed is obtained by worm gearing running in an oil bath. This gearing is most carefully cut, the thrust of the worm being taken up by ball bearings.

The 6 H.P. and 1 H.P. motors are mounted on the crab and have only one speed, being switched in and out of circuit without the use of any starting device. The lifting and transverse motions are limited to one speed. The 4½ H.P. motor gives the longitudinal motion, and has two speeds: full speed and half speed. The higher speed is obtained by halving the number of stator poles, this operation being performed by a throw-over switch. The starting and reversing is done by a second throw-over switch.

For cranes above 5 tons, the lifting and longitudinal motors are equipped with a starting device, connected to the rotor through slide rings. Such an arrangement has not the peculiar property of the series-wound continuous current motor, of self-regulation of speed in accordance with the weight being lifted; but this is the only advantage that the continuous current motor has over the three-phase machine. This, I think, is fully compensated for by the less delicate and complicated equipment the latter requires. The three-phase motor will stand a heavy overload or sudden reverse without fear of damage.

Usually the lifting motor is designed for a maximum speed at heaviest load. This speed cannot be increased for lighter loads, but can be regulated at will under such a limit.

The Liverpool Grain Storage and Transit Company, Limited, have adopted a three-phase plant for their storage warehouse at Bootle. It has been running some 15 months, and there are at present nine motors, giving a total of 150 H.P. The generator has an output of 165 H.P., and is coupled direct to a Belliss engine. They have no reserve generator, and do not stock any spare parts for either generator or motors. An extension of this plant is now in progress, consisting of two 48-H.P., and one 60-H.P. motors.

This installation furnishes an example where lighting and power is taken from the same mains. There are about 200 lamps, which are connected across two phases, the lamps being arranged so that the current is distributed equally over the three circuits, so as to maintain the balance of the system.

Another method of combining lighting and power on a three-phase system is to run a fourth wire from the common junction, if the star connection be used. The lamps are connected between this fourth wire and any one of the three main cables, thus doing away with the necessity for balancing the three circuits.

For mining work, the multiphase system is specially adapted, and already a considerable amount of work has been done in this direction. The General Electric Company, Limited, have recently sent out, from their Manchester works, some three-phase plant for several South African mines, particulars of which may interest you.

The largest of these plants was one sent to the Vogelstruis mine:—The generating plant consists of two 150-kilowatt three-phase generators. They are belt driven, at a speed of 300 revolutions per minute, with a frequency of 30 cycles and a pressure of 950 volts.

Three triplex single-acting pumps, with plungers 6½ inches × 8 inches, coupled direct by means of single reduction gear to 35 H.P. motors. These motors run at 360 revolutions per minute. The pumps are designed to work at a crank-shaft speed of 45 revolutions per minute against a water pressure of 300 lbs. per square inch. They are of American design, and were made by the Gould Company.

yards; each conductor having a copper area of ·145 square inches. The total length of the branch cables is 830 yards; each conductor having a copper area of 0·118 square inches.

A plant exactly similar to the Knight Central has been sent to Witwatersrand mine.

The following is a complete list of the motors supplied to the above three mines:—

All motors—30 cycles, 950 volts.

No.	H.P.	Speed per minute.	Starting device.	How connected.
7	35	360	In rotor circuit.	Geared to pumps.
3	35	360	" "	Belted to machinery.
28	20	360	" "	Geared to pumps.
1	10	‡70	Switched into circuit without resistance.	Belted to machinery.
6	5	870		

The generators for these three mines are all of the inductor type, At full load they give a commercial efficiency of 91 per cent., and the rise in temperature, after long continuous runs, is 25° C. The

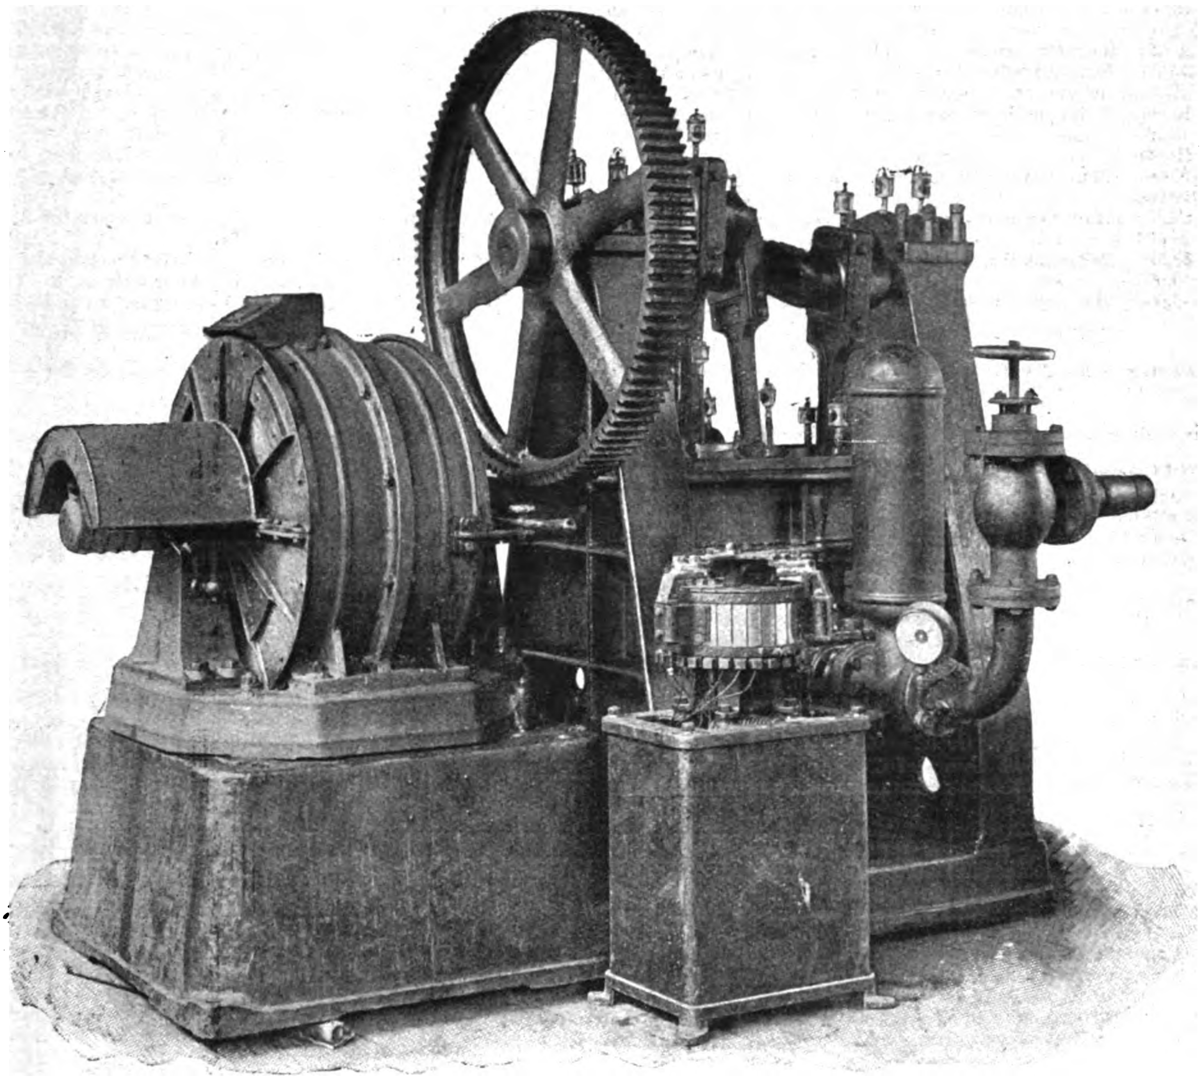

Fig. 4.—Motors of 20 H.P. with Three-Throw Pump.

Twelve triplex single-acting pumps, with plungers 4½ inches × 8 inches, of the same general design as the foregoing, coupled direct by means of single reduction gearing to 20 H P. motors, running at 360 revolutions per minute. These smaller pumps are also designed to work at a crank-shaft speed of 45 revolutions per minute against a water pressure of 300 lbs. per square inch.

The main cable is triple concentric, each conductor having a copper area of ·118 square inches. The length of this main cable is 1,866 yards. The branch cables are also triple concentric. There is one length of 430 yards, the sectional area of each conductor being ·047 square inches, and another length of 1,300 yards, with an area of ·0314 square inches for each conductor.

The above cables are lead covered and steel armoured.

Another plant was sent to the Knight Central mine, consisting of two 100-kilowatt generators, running at 450 revolutions per minute; the voltage and periodicity being as described for the Vogelstruis mine. There are three triplex pumps 6½ inches × 8 inches, and eight pumps 4½ inches × 8 inches, coupled direct by single reduction to 35 H.P. and 20 H.P. motors respectively.

The length of the main triple concentric cable for this mine is 900

main switchboard is so arranged, that the generators can be run in parallel.

As these mines are very wet, the motors were designed with water-tight and ventilated covers, as shown in fig. 4.

To enable the 20 H.P. and 35 H.P. motors to start up smoothly and gradually, they were supplied with starting resistances in the rotor. The 20 H P. motors were made in Manchester by the General Electric Company, Limited, and each machine was coupled to its pump, and tested separately at its full load for six hours, the rise of temperature being 25° C.

The York Gold Mining Company, of South Africa, have just installed a power plant, consisting of two belt-driven 50-H.P. three-phase inductor type generators, running at 750 revolutions per minute. These supply power to two 24-H.P. motors, the motors being coupled to Easton, Anderson & Goolden belt-driven pumps. They have one 3-H.P. motor connected to a centrifugal pump, and several small motors, which are belted to various kinds of machinery, and one 9-H.P. motor coupled direct to a continuous current dynamo, the output of which is 15 volts, 300 amperes, used for cyanide work.

(*To be continued.*)

PHYSICAL SOCIETY.

Ordinary Meeting.

Mr. Shelford Bidwell, President, in the chair.

Mr. A. A. Campbell Swinton read a paper and showed experiments upon The Circulation of Gaseous Matter in a Crookes Tube.

The stream lines within a Crookes tube are investigated by observing the direction and speed of rotation of a mica radiometer mill mounted on a sliding rod so that it can be moved along a line at right angles to the line joining the electrodes. The axis of the mill is at right angles to both these lines. If the mill is adjusted to a position between the flat plate and the cup electrodes, with its axis just sufficiently low to prevent equal and opposite simultaneous action on the top and bottom vanes, it rotates always in the direction indicating a stream from cathode to anode. The speed is greater when the flat plate is the cathode. If, however, the mill is now moved below this line, a point is reached at which rotation ceases, and below this neutral point the rotation is suddenly reversed. Reversal is only to be observed with high degrees of exhaustion; the rotation is never so rapid here as in the first position. The mill rotates, and the reversal may be observed, whether cup or plate is made cathode, and the direction of rotation below the neutral point is always opposite to that in the position above it. A small Wimshurst machine is as effective as an induction coil in producing these effects. The experiments are intended to establish the existence, at high degrees of exhaustion, of a true anode stream, *i.e.*, a stream that travels from anode to cathode just in the same manner as the cathode stream flows from cathode to anode. This anode stream is charged positively; it is exterior to the cathode stream; its velocity is less than that of the cathode stream, but its velocity increases as the vacuum is improved. It seems probable that, at high vacua, some portion of the positive electricity passing through the tube is carried by the positively charged atoms or particles that constitute the anode stream. At lower degrees of exhaustion, the discharge passes through the tube chiefly by interchange of charges from molecule to molecule—a Grothüs chain. At the very high vacua, however, when the mean free pass is considerable, there may be to some extent a regular and complete circulation of positive and negative atoms, some of which pass from anode to cathode and *vice versâ*, and deliver up their charges, not by interchange, but by direct convection, to the electrodes of opposite sign.

Prof. Boys said he did not feel altogether convinced by the experiments that the rotation of the mill was due to simple mechanical motion of the particles of matter between the electrodes. The weight of air left in the tube at such high degrees of exhaustion was extremely small; it was difficult to realise that its impact could produce the sudden mechanical effect observed at the moment of the reversal of the rotation of the mill.

Mr. Wimshurst thought it important to keep in mind the existence of mercury-vapour in the tube. He also referred to some experiments in which a bar of metal was used to explore a focus-tube, by observation of the changes of luminosity produced in different positions.

Dr. Chree said that if the rotations of the mill could be shown to indicate a velocity of the particles of the same order as that observed in Crookes's experiments, it was safe to assume the existence of a similar cause. This might be important in deciding as to the general truth of the bombardment theory of Crookes. He asked whether the rotation had been investigated within the dark space around the cathode.

Mr. Appleyard suggested that in tracing the cause of the rotation it would lead to simpler results if the vanes of the mill were made of some light conducting substance. Mica introduced difficulties owing to its retention of the charges.

Prof. Boys pointed out that this could be done by gilding the mica.

Mr. Campbell Swinton, in reply, said that the objection raised by Prof. Boys to the mechanical theory of the rotation would apply equally to the whole theory of electro-radiometry, including the case of the mill used originally by Crookes in the direct path of the cathode-stream. But it must be remembered that although the mass of matter present within the tube was very small, its velocity was proportionately great, it was of the order of 9,000 kilometres per second; hence the contained matter might be conceived as capable of producing the observed acceleration, and Crookes's bombardment theory might with safety be adopted as a safe working hypothesis. In the tubes used for these experiments the exhaustion was carried so high, that the negative dark space appeared to fill the whole tube. He had, so far, only tried mica for the vanes; but he thought it would be important to observe the result with a substance that did not retain the charges.

Mr. A. Stansfield then read a paper on Thermo-Electric Pyrometers.

In obtaining photographic records of the readings of thermo-electric pyrometers, the range of measurement is limited by the size of the photographic plate. For long ranges of temperature, the sensitiveness of the galvanometer must therefore be small. When it is desired to examine the temperature changes in detail, as for instance at the melting points and freezing points of metals, it is necessary to employ some device for giving a more open scale for the short temperature ranges that include those particular points. For this purpose two galvanometers are arranged in parallel, and so that they have their deflections recorded on the same photographic plate. The less sensitive galvanometer covers the entire range of temperature throughout an observation; the other is brought into use for magnifying special portions of the range. In this latter case part of the electromotive force of the thermo-couple is compensated by an opposing electromotive force, applied at two points of the circuit, from a battery of Clark cells in series with a high resistance. The recording apparatus consists of a photographic plate mounted on a float, that rises steadily when water is admitted into a cylinder. The source of light is a glow lamp, enclosed in a wooden box. A brass tube, with a rectangular diaphragm at the end nearest the lamp, cuts off all light except that from a selected piece of vertical filament. Light from this filament is reflected by the plane galvanometer mirror, and is focussed upon the photographic plate by a lens in front of the galvanometer; this method was suggested by Prof. Boys. The "cold" junctions of the thermo-couple are both inserted into a hypsometer. Very serious discrepancies exist between the indications of couples having nominally the same composition; they are too great to be attributed to accidental differences in the constitution of the alloys. Although with platinum alloys, coupled with platinum, 10 per cent. of iridium gives a more powerful couple than 10 per cent. of pure rhodium, the partial substitution of iridium for rhodium very considerably lowers its thermo-electric power. This result suggests that the change in the thermo-electric power of a metal depends upon the extent to which it is saturated with the alloying metal; thus 10 per cent. either of rhodium or iridium would, *per se*, more completely saturate the platinum than would 10 per cent. of a mixture of the two metals. The author discusses a series of curves derived from his experiments. He concludes that, thermo-electrically, there may be two classes of metals (1) the ordinary metals, for which the curve representing the first differential of electromotive force with respect to temperature is a straight line, and (2) the platinum metals, together with a few such as nickel and cobalt, for which the curve of that differential, multiplied by the absolute temperature, is a straight line.

Dr. Chree discussed the curves, and asked how far stirring affected the results; he was inclined to think that stirring was a mistake.

Mr. A. Campbell inquired whether the galvanometer kept its zero sufficiently well throughout the tests.

Mr. Stansfield, in reply, said he had also come to the conclusion that stirring was a mistake; and it was a mistake to use a large quantity of metal. The pyrometers were sensitive to about a tenth of a Centigrade degree. He had experienced great difficulty with the zero of the galvanometer.

The President proposed votes of thanks to the authors, and the meeting adjourned until April 22nd.

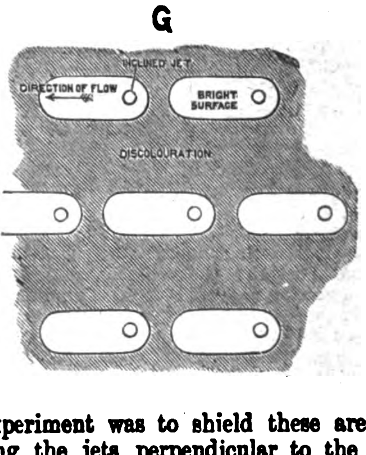
ON SOME RECENT INVESTIGATIONS IN CONNECTION WITH THE ELECTRO-DEPOSITION OF METALS.*

By J. C. GRAHAM.

(*Concluded from page* 358.)

It was thought that this might be cured by inclining all the jets towards the face of the cathode at an angle of 85°, instead of directing them perpendicularly against the face of the cathode. The result, however, instead of being an improvement, was much worse than before. This is shown in Diagram G.

G

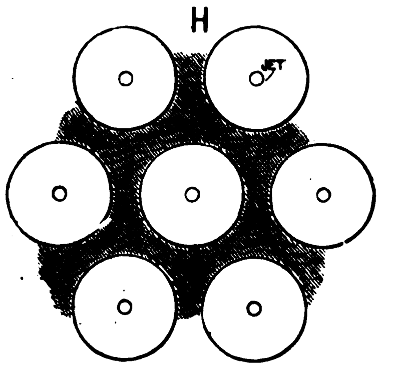


The next experiment was to shield these areas of interference, keeping the jets perpendicular to the face of the cathode. This was readily done by cutting a number of round holes out of a thin sheet of vulcanite, through the centres of which the jets played, as shown in fig. H.

A very beautiful deposit was obtained in this manner, at 3,000 amperes to the square metre. In this case the cathode was moved slowly to and fro in front of the jets to insure

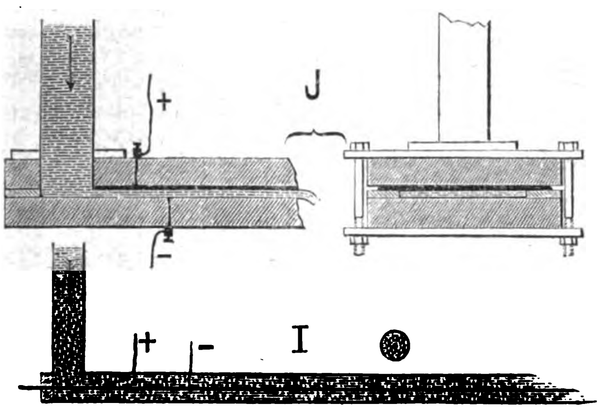
* Communicated to the Royal Society.

a uniformly thick deposit over the whole surface of the cathode.



Shield with Holes.

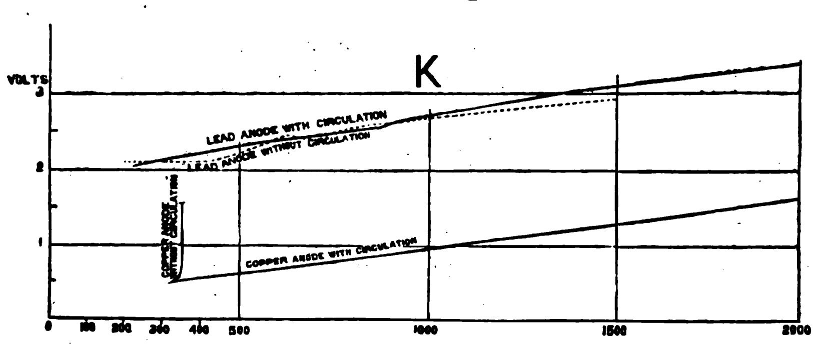
As a very rapid circulation of the electrolyte appeared to be the principal condition of success, two new forms of apparatus were devised, which are shown diagrammatically in Diagrams I and J. The one for producing the circula-



tion over a wire, the other for producing it over a flat surface.

Taking Diagram J, which shows the apparatus for depositing strips or sheets. The electrolyte was forced with great rapidity by means of a centrifugal pump, through the pipe, and through the space enclosed between the anode and the cathode, and thence back to the elevated tank to which the pipe is connected.

In order to ascertain the difference of potential between the anode and the cathode at various current densities both with lead and copper anodes, a number of observations were made, the results of which are shown in Diagram K.



Amperes per Square Metre.

The volts are measured vertically, and the amperes per square metre are measured horizontally. The continuous thick black line at the top shows the voltages with a lead anode, the thick red line lower down shows the voltages with a copper anode.

It will be noticed that in the form of apparatus used for these experiments, that the anode as well as the cathode was very energetically washed, and in order to further examine the effect of washing, a lead and a copper anode were tried in an ordinary tank where no circulation was taking place; all the other conditions of the experiment being as nearly as possible the same as when there was circulation.

The dotted black line at the top shows the voltages with the unwashed lead anode, showing that the washing has not much effect on a lead anode.

But with a copper anode the effect is most striking.

The current for this last experiment was in the first place taken from a single cell, through a resistance, and the curve is shown by the black line at the bottom left-hand corner of the Diagram K. It will be seen that the currents and voltages rose pretty regularly to about 300 amperes to the square metre: at this point the voltage began to rise more rapidly, and at 350 amperes the voltage began to rise rapidly, and in a few minutes rose from ·56 to 1·57, the current at the same time falling off from 350 amperes to 106.

This experiment was repeated with two cells, but the movements were so rapid that I have not attempted to plot them. The current at the commencement was 305 amperes and the volts ·44. The volts rose almost immediately to 1·42, the current falling at the same time. The volts then rose more slowly and at the end of half an hour had risen to 3·66, while the current had fallen from 305 amperes down to the insignificant amount of 30·5.

Lastly, in order to get a more extreme example of this phenomenon, the anode and cathode were coupled to the 100-volt main of the Kensington and Knightsbridge Company and the current taken through a water resistance.

A current of 122 amperes per square metre was allowed to pass and kept nearly constant. The voltage rose rapidly to 26 volts and remained pretty constant at that figure.

It should have been mentioned that the anode and cathode were well cleaned and rubbed bright with emery paper, before making each of the above experiments. The cathode was a square plate of copper having an area of 10 square inches. The anode was the same size, and they were placed about 1 inch apart in the electrolyte.

This tendency of the voltage to rise abnormally when a certain current density is reached, was not noticed with lead at all, and was not observable with washed copper anodes until about 2,000 amperes to the metre had been reached.

Some of the preceding experiments appear to point to the conclusion that so long as a path through the copper molecules can be maintained for the current, but little, if any, of the current will pass through the hydrogen molecules; the current will, in fact, follow the line of least resistance, and in order to see whether this was true of iron as well as of hydrogen, a dilute solution was prepared which contained iron and copper as sulphates in the following proportions:—

Water	100·0
Copper	·3
Iron	·1.

A current at the rate of 550 amperes per metre was passed, the electrolyte being circulated in the manner shown in Diagram J, and the deposited metal was analysed to ascertain whether any iron had been thrown down with the copper; not a trace was discovered.

This was repeated with half the amount of copper above mentioned in solution, viz.:

Water	100·0
Copper	·15
Iron	·1

The amperes being reduced to 330. Again no iron was found in the deposit.

A considerable number of experiments were also made for the purpose of ascertaining whether soda, potash, zinc, or aluminium, if present in large quantities in a solution of sulphate of copper, would alter the character of the copper deposit; so far as could be judged by the eye they made no difference, but the deposits were not analysed.

The fact that the current will pass through the copper molecules in preference to passing through the molecules of other metals, which may be in solution so long as a path through the copper molecules is maintained, appeared to offer a ready means of depositing copper in an almost pure state from the very impure solutions which are obtained by lixiviating certain ores.

The Rio Tinto Company in Spain produce very large quantities of such solutions, and they were good enough to send the author samples of some of their solutions. The strongest of these solutions was analysed by Mr. Swinburne and found to contain the following metals which were all assumed to be present in the form of sulphates.

Copper	11·09	Grammes per litre of the solution.
Iron	17·31	
Cadmium	0·22	
Aluminium	0·63	
Zinc	2·29	
Magnesium	0·24	

The solution, it will be observed, contained only about 1 per cent. of copper. From this solution the copper was thrown down without any difficulty in the form of both wires and sheets by the apparatus shown in Diagrams I and J. The current for the wires was about 550 amperes to the metre, and no difficulty was experienced in drawing the wire so deposited, nor did the wire show any signs of brittleness.

The current for the sheets was considerably denser than in the case of the wires, a perfectly good deposit being formed.

The author is also much indebted to the Tharsis Company who kindly sent him samples of the impure solutions of copper prepared by them from ores which they treat.

One of these samples was analysed by Mr. Swinburne, and found to contain the following metals, which were believed to be present in the form of chlorides.

Copper	32·54	per litre of solution.
Iron...	7·42	

Aluminium	not determined.
Zinc	
Potassium	
Sodium	

Although here, as with the Rio Tinto solutions, no difficulty was experienced in depositing the copper, yet it was found to be impossible to get a deposit of a good colour at any current density however small. The deposit instead of being a pale salmon colour as desired, was invariably of a dirty brown colour, and for some time this was supposed to be due to the presence of some other metal, but it was found that copper thrown down from a solution of pure chloride of copper was of the same dirty colour, and that the addition of sulphuric acid in very considerable quantities to a solution of chloride of copper made very little difference in the appearance of the deposited metal.

The discolouration, therefore, appeared to be due to the presence of chlorine, and to determine this point a saturated solution of sulphate of copper was taken, and to it was added commercial hydrochloric acid in the proportion of two cubic centimetres of hydrochloric acid to one litre of the copper solution. This amount of hydrochloric acid made hardly any perceptible difference in the appearance of the deposit. With three cubic centimetres a change became noticeable, and with six cubic centimetres of hydrochloric acid to one litre of saturated sulphate of copper, the deposit was about as dark in colour as if the whole of the copper had been present in the form of a chloride. In these experiments the current was at the rate of 1,000 amperes to the metre.

It, therefore, appeared that to treat the Tharsis solution effectively, it would be necessary to convert the copper into a sulphate and to get rid of the chlorine. This was economically effected in the following manner: soda or lime were added in quantities just sufficient to throw down the whole of the iron as a hydrated oxide, leaving all the copper chloride in solution. After the iron precipitate had been separated out, a further quantity of soda or lime was added to the clear solution, and the whole of the copper was thus thrown down as a hydrated oxide: this oxide of copper was then very thoroughly washed and dissolved by sulphuric acid, and from the solution so obtained the copper was easily thrown down as a perfect deposit.

One advantage of this method of working is that the dilute solution of chloride is converted into a saturated solution of sulphate.

The author is much indebted to Mr. Crompton, who very kindly allowed him to use his laboratory at Thriplands during all the earlier experiments mentioned in this paper.

AN ELECTRICAL HYPOTHESIS FOR THE SOLAR AND PLANETARY SYSTEMS, AND SOME OF THEIR ASSOCIATED PHENOMENA.

By DELTA.

IV.

The Atmospheric Electrical Potential.

Although Exner's determinations alone, absolutely prove, and with sufficient exactitude, the measure of the increase of potential at a strikingly high rate in proportion as the distance from the earth increases; this fact of immense and still unrealised importance, had already been discovered by Sassure and by Volta of immortal memory over a century ago.

Gay Lussac's Aerostatic Determinations.

The aerostatic experiments of the great chemist, Gay Lussac, in 1805 corroborated Volta's discovery.

Gay Lussac's temperature and other results have been plotted on the diagram, fig. 12, along with Exner's electrical

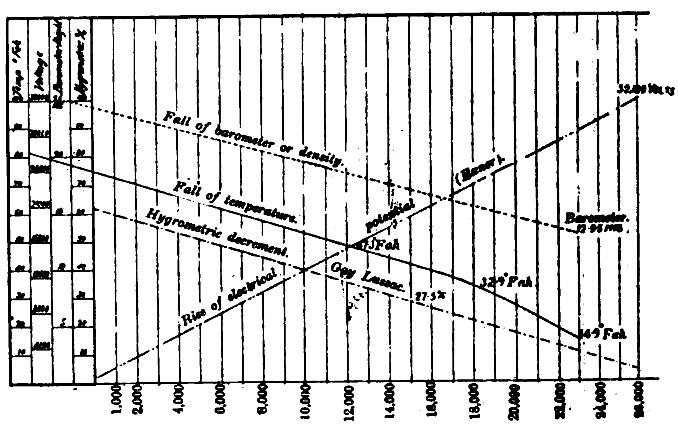


Fig. 12.—Distance from Earth in Feet.

Graphic diagram, showing the remarkable correlative evidence of the fall o the barometer, or density of the atmosphere, the reduction of aqueous vapour and the temperature, and the rise of the electrical potential—with the increase of distance from the earth.

determinations. It will be noticed that at the height of 23,040 feet above the level of the sea the temperature had fallen from 82° F., the temperature at the earth's surface to 14·9° at the altitude defined.

Gay Lussac found that the density of the atmosphere decreased at a height of 22,912 feet to less than half its value at the surface of the earth—the barometer had sunk to 12·95 inches.

The hygrometric researches proved that the aqueous vapour proportion fell from 62 per cent. at the earth down to 27·5 per cent. at an altitude of 15,190 feet.

He (Gay Lussac) also found at an altitude of 23,000 feet that the chemical constitution of the air had undergone no change.

If the writer's hypothesis is correct, it would mean that the fall of the barometer should proceed *pari passu* with the fall of temperature. The diagram shows that the fall is parallel, and is, therefore, consistent with the theory.

The Fall of Temperature with Increased Altitude.

The fall of temperature in Gay Lussac's aerostatic experiments is as follows:—

Temperature at the earth	= 82°	Fahr.
" at a height of 12,125 feet	= 47·3°	"
" " " 18,636 "	= 32·9°	"
" " " 23,040 "	= 14·9°	"

In the verbal demonstration of the solar electrical hypothesis it is, perhaps, unnecessary to say that the expression vacuum is merely employed to explain an imaginary condition of the extreme tenuity of the atmosphere, that will permit the transmission of high potential currents with a minimum of loss. It is well known that, in proportion as the atmospheric tenuity is increased (within certain not as yet well-defined limits), is the electrical resistance reduced; this can be proved by connecting the terminals of an electric collector machine with a so-called vacuum tube; it will be found that a far longer discharge can be obtained than if the terminals are divided by an atmospheric interspace of normal density. It is, however, not absolutely essential to assume such a rarefaction in order to obtain a miniature resemblance of solar electrical effect.

A Laboratory Demonstration.

Fig. 13 is a diagram intended to represent the remarkable luminous effect on two terminal spheres of a Voss machine, the experiment can be repeated by anyone.

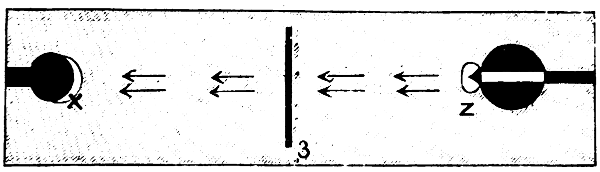

Fig. 13.—Voss Electrical Collector or Machine.

Diagram showing the luminous surfaces on two spheres, x and z, by the emission and reception of electrical energy of high potential.

An opaque diaphragm 3 can be placed so as to intercept any possible reflection, but the luminous effect is not reduced. The human hand placed in the position of the diaphragm will realise a sensible reduction of temperature, but will not be influenced by the flow through it of the electrical energy.

The high potential (brush discharge) current across an air interspace produces at the projection from the discharge sphere a luminous effect, which is repeated on the reception surface of another and *vis-à-vis* sphere. To prove that the second luminous surface is not merely the effect of reflection from the *vis-à-vis* luminous surface, one has only to place an opaque board so as to intervene between the two spheres, as shown on the diagram, there will still be the same dual luminous evidence. If the opaque board is replaced by the human hand a sensible cooling influence will be evident, but no electrical effect will be produced and the energy flow will not be appreciably affected. Both at and around the projection of the negative sphere terminal, which can be considered to represent the solar sphere, and at the surface of reception of the positive sphere terminal representing the earth, there will be noticed in the dark a luminous area, relatively great in proportion to the surface of the sphere; if a pointed projection was provided for the positive sphere and on the opposite side to the luminous surface, the electrical energy would be dissipated into the atmosphere by which it would be again collected by the Voss machine or other electrical collector, of which the solar sphere is an example. Now referring to diagram *a* of the positive sphere terminal, *x* is moved in a circular line around the negative sphere *z*, the electrical energy will follow this movement and take the direction of a radial line drawn across the centres of two spheres.

The only difference between the electrical solar hypothesis and this laboratory proof, is the fact that in the latter the interspace is of atmospheric density, but even then there is practically no luminosity in the interspace except in or about the surfaces of emission and reception of the electrical energy.

It may be suggested from the proof adduced, that in order to produce the luminous effects at the surfaces of emission and reception, it is not necessary that the solar and terrestrial luminosity is produced by the increased resistance of their respective atmospheres to the flow of electric energy. This is granted, but in order to satisfy the conditions enforced by the law of the conservation of energy, it is necessary to assume such a high rarefaction or reduced density between the sun and the planets as will permit the unimpeded flow of electrical energy, and we know, as a positive fact, *that the density of the atmosphere* does decrease in a now well-defined proportion to the distance from the earth's surface.

The Movement of the Planetary Bodies.

The hypothesis that the entire celestial or interplanetary and interstellar space is really an accumulator reservoir, or ocean of low pressure electrical energy, that will permit, as does the earth's atmosphere (which constitutes part of this electrical ocean), the flow through it of high intensity electrical currents, permits the application of the magnetic attraction theory to displace and fulfil the conditions of the Newtonian gravity hypothesis.

The author suggests that the rotation of the planets may be effected somewhat in the same way that an electric motor is rotated, and their high and generally compound rotation may give them their distinctive orbits. No doubt it could be demonstrated that a rotation could be given to a spherical body, which would propel it in a certain specific direction, and if the orbits of the planets were mathematically circular, this hypothesis would apply; but the fact that the orbits of the interplanetary and interstellar bodies do not generally assume this form, inclines one to the opinion that the orbit is the result of the attractive influence of the great central solar electrical body, and that the spherical rotation is the result of the electrical energy rotating the polarised planets in some way, as a current rotates an armature.

As far as the moon is concerned, it is suggested that the electrical attraction of the earth, added to the rotating influences set up by the solar electrical centre, may be some explanation of its peculiar orbit, surbordinate to the planet earth.

Saturn and its Rings.

The movement of the rings of the planet Saturn, in their particular and regular plane of inclination, may constitute the source of motion of this planet, assisted, as it would be, by the rotation of the planet itself.

The constitution of the rings is not yet adequately defined; the rings may be associated with an atmospheric annulus, by which the associated rings are illuminated.

The Cometary Orbit.

The cometary orbit will also be produced, it is suggested, in a somewhat similar way to that of the planetary bodies, but their particular form is apparently influenced by the contiguity of other planetary electrical conductors.

The strange feature of the cometary orbit, is the sudden reversal of the direction of cometary movement at the aphelion.

Law of Compensation of Electrical Energy.

It may be rightly argued that as the electrical energy is absorbed in generating luminous and thermal effects, and incidentally in maintaining innumerable other forms of energy that there will be a constant loss of the energy projected from the solar electrical supply stations.

There is the great absorption of energy in internal—or interterrestrial—electro fusion work which is always going on, as we know by the occurrence of volcanic eruptions, by the increase of temperature in deep borings, and by the contraction of the earth's skin. But it may here be remarked that although we may, by electrical resistance effects, raise metals to a state of fusion, if this action is performed in a *reducing atmosphere*, it doesn't necessarily imply that the metal is being burnt up or in any way altered; and, further, under such conditions the additional electrical energy that will be required to maintain the metal in a state of fusion is only that required to compensate for the loss of the heat that flows to that part of the surface of the earth, that is, in its rotation, removed from the direct influence of the sun's supply of electrical energy.

It is, therefore possible, that when the electrical energy was initially introduced to the conductor planetary body, there would then be an immense absorption of electrical energy in effecting internal fusion work, and at this time all the igneous effects noticed in the shell of the earth and producing contraction of the bulk of the sphere would be then effected. However, this is an aside from the subject of the article.

Becquerel (one of the very many illustrious *savants* by which France has enriched the world) suggested that the atmospheric electricity was the product of chemical changes always preceding and induced by chemical action. Here, therefore, have we the basis of the law of compensation of electrical and solar energy.

The proportion of solar electrical energy absorbed in stimulating chemical action will by electrolytic, electro-thermal, and other changes occurring both on the surface and in the interior of the earth, be exactly returned to the low pressure electric interplanetary ocean, and this great accumulation of energy will renew the solar centre in proportion to its supply of energy to planetary and other bodies in the celestial space.

The Atmospheres of Jupiter, Mars, and Venus.

The surface of Jupiter is enclosed in varied masses of flocculent cloud form. This planet has a highly reflective surface—so much so that the effect of its luminous atmosphere is incidentally reflected, and with a loss of 23 per cent. of the initial energy, so that the absorption by this planet of solar electrical energy is very slow.

Herschel identified the dark belts of the atmosphere of Mars as tracks of comparatively clear sky.

These dark belts, it is suggested, are composed of an atmosphere of extremely low density, offering little, if any, resistance to the flow of the high intensity electrical energy emitted from the orb of solar electrical supply.

An alternative explanation is that the dark belts cover the surface of emission from this planet of low intensity electricity and the light or luminous belts constitute the atmospheric surfaces of introduction to the planet Mars of the high intensity electrical currents.

Luminous atmospheric effects are conspicuous in Venus.

When this planet is at inferior conjunction or below the sun, its entire disc periphery is not uncommonly rimmed with a glorious halo of luminous rays, bent inwards, as if by the action of lens.

(*To be continued.*)

ALUMINUM AS A RIVAL OF COPPER AND BRASS FOR ELECTRICAL CONDUCTORS.*

By ALFRED E. HUNT, S.B., President of the Pittsburg Reduction Company.

(*Concluded from page* 321.)

The power of withstanding corrosion is greatly in favour of aluminum as an electrical conductor over copper. Copper does not change in dry air, but in moist air it becomes covered with a green layer of basic carbonate of copper, which, itself, has a corroding action, and does not coat and protect the underlying copper from further corrosion. Ammonia, in contact with copper, absorbs oxygen and the copper dissolved, in consequence of the formation of a soluble cupric-oxide and ammonia. This action is especially a source of trouble where copper wire is used in connecting rail joints in the tracks of electrical railroads, where the ground is often subject to ammoniacal solutions.

Aluminum, similarly, is not acted upon in dry air, and the corrosion in moist air is of the oxide of aluminum, alumina, a harmless salt, which forms an impenetrable coating on the metal, and protects it from further corrosion to a considerable extent. Ammonia solutions act on aluminum only upon the surface, attacking it, and leaving behind a more resisting surface coating of a brown colour containing silicon, which resists corrosion from dilute mineral acids and dilute solutions of organic acids, as well as moist and dry air. Subject to sulphur gases, such as locomotive flue gases, aluminum withstands corrosion better than copper.

If kept free from galvanic action with any other metals electro-negative to itself, aluminum is far less easily corroded than copper.

The difficulty of soldering or brazing aluminum is the chief drawback to its use as an electrical conductor. Aluminum can be soldered strongly, but it is a more difficult and slow operation at best as compared with copper, and there is much more rapid weakening of the soldered joint due to galvanic action between aluminum and the metals of the solder than with the less electro-positive metal, copper.

In many places the aluminum can be first coated with copper, and the soldering or brazing operation made on the copper surfaces thus formed.

Several forms of joints have been successfully used to avoid the necessity of soldering, the best forms being to use thin aluminum sheets to wrap the joints, and to twist or otherwise bind with the aluminum bars or wires to be joined. These wrapped and twisted joints with aluminum sheets can be left smooth on the outside when desired, can be made much stronger than the body of the conductors, and are really a more serviceable job than soldered or brazed work in many cases with copper. One very practical way of making joints of aluminum wire is to roll the thin aluminum sheet, of about 6 inches width, into two cylinders from opposite edges of the sheet. These double cylinders are very cheaply made on mandrels in a lathe. The ends of the wires to be joined are inserted in these cylinders from opposite ends, and both the wire and sheet twisted with pliers until a firm joint is secured, much stronger than the body of the wire. The joint can readily be made impervious to the air and moisture.

The C. McIntire Co., of Newark, N.J., have a patented joint which is made very much along the lines of this joint. Information regarding their patented form of joint can be obtained by correspondence with them as above. Also the American Electric Fuse Company, Chicago, Ill., make a very satisfactory joint.

Another disadvantage which handicaps aluminum in special uses for electrical conductors will be where the material has to be insulated, that the cost of insulation will be approximately one-third greater for the larger section required in aluminum over the cost for the smaller section of copper required for the given conductors; and where aluminum is to economically compete for insulated conductors the price of the aluminum will have to be further reduced to meet this contingency.

Aluminum is soon to be placed in an extensive line of conductors where this added extra cost of insulation will be determined by actual fabrication. The Pittsburg Reduction Company in this particular case agreeing to pay the added costs, in order that actual experience may be gained as to their relative amounts.

There are certain places where aluminum will be at a disadvantage over the smaller section of equal conductivity of copper, in ducts or conduits where space is a considerable item. In such cases, the use of aluminum would necessarily be prevented.

An ample field for the employment of aluminum for some time to come, however, seems open at the present time for bare transmission lines, especially for high potential long distance work and for long distance telephone lines, and for rapid transmission telegraph lines.

Aluminum, next to gold, is the most malleable of all the metals, and is much more malleable than copper.

Aluminum in ductility stands next to copper, and is easily drawn into all sections that are furnished in copper for electrical conductors.

Aluminum can be furnished fully as uniform in its composition as copper.

The metallurgy of copper is comparatively complicated, owing to the difficulty of converting its ores into the oxide free from impurities. In most of the copper ores used, sulphur, lead, and iron are contained, as well as small quantities of other elements, as arsenic and antimony. All of these elements in metallic copper very materially lower its electrical conductivity. The native pure copper of the Lake Superior region enjoys the preference, due to its uniformity and freedom from impurities, for many purposes, but for electrical conductors the electrolutic copper is most used.

Aluminum can now be furnished rivalling, for electrical conductors, at least 99·50 pure, it is granted not as yet, in purity of composition the best electrolytic copper used for the purpose of electrical conductors. When a fused metal is obtainable, undoubtedly it will more nearly rival copper for electrical conductors section for section.

Aluminum has been already in successful operation as an electrical conductor for some time. The first use in a large way was with the conductors for the electric current at the at the Niagara Falls works of the Pittsburg Reduction Company, where it has been used since the year 1895. The currents were of several thousand horse-power each and of very large volume and comparatively low voltage. Both in conducting power, freedom from heating effects, power of withstanding corrosion, ease of making, wear, and efficiency of joints, the aluminum conductors have given better results than copper used for the same purpose.

In the Chicago Stock Yards, a mile of aluminum wire of No. 11 gauge has now been in use for some time upon a telephone line that has been badly corroded out in copper wire, due to its being frequently subjected to sulphur gases from passing locomotives. The aluminum line is giving

* Advance proofs of this paper were courteously forwarded through the Secretary of the Institution of Electrical Engineers.

good satisfaction, and is withstanding corrosion much better than did the original copper wire subjected to the same influence.

If the theory be true that the passage of high voltage alternating currents of great frequency is largely upon or near the surface of the conductors only or mainly, then the larger section of the proposed aluminum conductors will make them especially adaptable for such currents.

On telephone lines it has already been determined that as good sound transmission is obtained with aluminum of equal section as with copper, in ordinary lengths of less than 10 miles of wire. No comparative results, however, have as yet been determined on long distance telephone transmission; but the evidence would seem to point that a much less section than 160 of aluminum to 100 of copper will give equally good results.

Aluminum is now being used to replace brass very considerably in the arts, as it is sold in the open market at rates which make it 10 per cent. cheaper, section for section, than brass.

For electrical purposes, the metal can be advantageously used to replace brass in a good many ways. Commercially pure aluminum as furnished to-day contains less iron than does commercial brass, and is, therefore, more non-magnetic than brass.

The electrical conductivity of aluminum is far superior, section for section, to brass. Almost every electrical apparatus of present construction in which an iron core—usually a laminated iron core—is used, in motors, generators, or transforming machinery, has spaces for ventilation, and the spacing is made by the means of drawn bars, flat rods or angles or tee-shape pieces. Brass has been almost invariably used for this purpose in the past—probably on account of its non-magnetic properties as compared with iron or steel. Drawn aluminum sections can be furnished at a price which is 10 per cent. cheaper than brass, section for section; and on account of the lightness of aluminum, it can be advatageously used.

Where a low electrical conductivity is desirable, as in parts that are moved in a magnetic field, to prevent the occurrence of eddy currents, aluminum can be alloyed with zinc and other metals that will lower its electrical conductivity to the desired point.

ERECTION OF OVERHEAD TROLLEY LINES.

By GEORGE C. SILLAR.

When erecting overhead trolley wires for electric tramways, care must be taken to allow sufficient dip in the wire to provide for the maximum reduction of temperature during the winter season, and so avoid overstraining of the wire.

To enable this to be determined readily, the accompanying diagram may be of assistance in saving time in calculations.

In plotting the diagram the following have been assumed:—

1. That the tensile strain of trolley wire is equal to 25 tons per square inch.

2. That the safe working strain is one-fourth the tensile strain.

3. That the elongation of the wire is 0·0018 times between the freezing and boiling points of water, or 0·0001 times for each 10° F. rise.

4. That the dip of a wire varies as the square of the span, which is not theoretically correct, but for all practical purposes it is so within the limits of span and dip met with in trolley wire erection.

It will also be recognised that for a given span, and with a given strain per square inch of section of wire, the dip will be the same for all sections of the same material.

Referring to the diagram, the curve on the upper part gives the rate of increase of dip for a copper wire, having been determined experimentally, as follows:—

The wire experimented upon was fixed firmly at one end while the other was passed over a pulley exactly 100 feet distant.

The wire was then loaded at the pulley end with a weight equal to one-fourth its tensile strain.

The dip under these conditions was then measured and taken to represent the minimum dip at 0° F., after which the length of wire between the points of support was increased by an amount equal to a rise of temperature of 10° F., and the dip again noted, which latter proceeding was repeated a sufficient number of times to allow for a range from

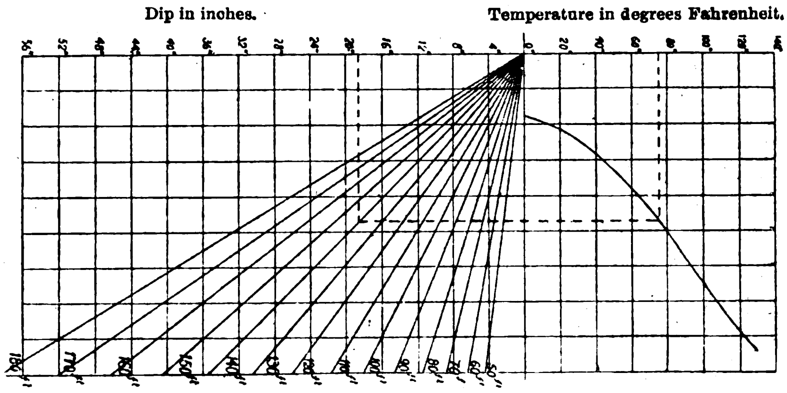

Diagram giving Dips for any Temperature from 0° to 130° Fah. at any Span from 50 Feet to 180 Feet.

zero F. to 130° F., these being assumed to be the minimum and maximum temperatures to be provided for in this country.

On the lower part of the diagram, diagonal lines are drawn representing the spans, and are arranged so that the distance between them on any vertical line varies as the square of span which they represent, consequently the dip for any one span being known the dip for any other span can be read off without trouble.

It will be obvious how the top and bottom sections of the diagram are intended to be used, but to take a concrete case assume that it is required to determine the safe minimum dip for a span of 140 feet at a temperature of 75°.

Starting from 75° on the temperature column, carry the eye horizontally till it meets the curve, from which point drop a vertical line to meet the diagonal line representing the given span of 140 feet.

Opposite this point on the left hand column will be read the dip in inches or 18·4 inches.

This sequence of operations is indicated by the dotted line.

THE UTILISATION OF MAGNETIC ACTIONS FOR THE DIRECT TRANSFORMATION OF HEAT INTO MECHANICAL WORK.

In a note presented to the Académie des Sciences on October 11th, and reproduced in full in *L'Industrie Electrique* for October 25th, 1897, No. 140, p. 456, M. Marcel Deprez, after many other writers, called attention to the possibility of transforming thermic energy into work by utilising the variations of the magnetic constants with the temperature and the remarkable magnetic properties of the alloys of iron and nickel recently discovered by our *collaborateur*, Ch. Ed. Guillaume.

M. Marcel Deprez's note* concluded with this seductive promise:—

"In a future paper I shall show how the same principle enables us to transform heat directly into mechanical work, and I shall describe the conditions under which these two kinds of apparatus, the thermo-magnetic motor and generator, would be capable of giving really practical and economical results."

We have looked in vain since in *Comptes Rendus* for the promised communication, but in the *Revue Générale des Sciences* of January 30th, 1898, we find an article by M. Marcel Deprez which supplies its place, and seems to imply that the thermo-magnetic motor and generator capable of giving really practical and economical results have yet to be realised, for the writer begins with the following declaration:—

* See Electrical Review, February 18th.

"A profound study of the question has led me to the conclusion that if these results are ever obtained, great difficulties will have to be overcome," and the object of the article is to show the nature of these difficulties.

The principle of the thermo-magnetic motor, to which M. Marcel Deprez applies the ferro-nickel alloy, consists in arranging a rod of this alloy in a magnetic field, and in making it revolve on an axis perpendicular to the direction of the field, and to this rod. It is rendered alternately magnetic or non-magnetic by cooling it and heating it in succession between the limits of temperature, at which the magnetic properties appear or disappear completely. For each revolution of the rod of ferro-nickel, two successive coolings and heatings must be produced, and the mechanical cycle will consist of four quarters of a revolution, two of which are motive, and are separated by two others that are non-motive, an action similar to that of a single-action engine with two cylinders, the cranks of which are fixed at 180°.

A first calculation shows the writer that by using a moderate magnetic field, of an intensity of 1,000 gauss, and a variation of temperature of 50° C., a variation for which the ferro-nickel is supposed to be magnetised or demagnetised completely, the efficiency would not exceed $\frac{1}{2000}$. In order to produce a quantity of mechanical work equal to 1 H.P.-hour (270,000 kgm., or 557 calories kg-d.), we should have to furnish 1,270,000 calories, representing the equivalent of 150 kg. of coal.

To give an idea of the dimensions to be given to the apparatus intended to revolve between limits of temperature not exceeding 50° C., the writer mentions the fact that in the furnaces of locomotives the heating surfaces do not, at the most, give off more than 200,000 calories per square metre per hour.

The second part of the article is devoted to showing how these conditions may be improved by increasing the intensity of the magnetic field and bringing it to 10,000 gauss, by employing a special mode of heating and cooling and by making the body which serves as a vehicle for the heat pass successively over a series of rods composed of alloys varying in the proportions of their composition and in their magnetic properties.

By using hypothesis after hypothesis, and assuming as extremely probable that the principle of Carnot is applicable to thermo-magnetic phenomena, M. Marcel Deprez arrives at finding—but not at demonstrating—that the efficiency might rise to 3 per cent., *i.e.*, to that of a steam engine of moderate power consuming about 3 kg. of coal per H.P.-hour.

Unfortunately, M. Marcel Deprez assumes the organic efficiency of the apparatus to be equal to one, which is excessive for one so heavy, bulky, and cumbersome as that of which he describes the principle; moreover, the rapid cooling and heating of the thermo-magnets must be obtained by the *mechanical* and alternating circulation of a liquid, which circulation, it seems, must absorb a power which is greater than that developed by the thermo-magnetic motor, and which is not taken into account at all.

The thermo-magnetic motor of M. Marcel Deprez seems, therefore, destined to be consigned to oblivion like the famous pyro-magnetic generator which Edison presented so triumphantly in 1888 to the American Association for the Advancement of Science.

In not presenting his second note to the Académie des Sciences, M. Marcel Deprez has shown his discretion, but we feel it our duty not to leave our readers too long in the expectation of a "thermo-magnetic motor and generator capable of giving really practical and economical results." They know now the opinion of the writer, an opinion based on "a profound study of the question."—E. H. (*L'Industrie Electrique*).

NEW PATENTS AND ABSTRACTS OF PUBLISHED SPECIFICATIONS.

NEW PATENTS.—1898.

Compiled expressly for this journal by W. P. Thompson & Co., *Electrical Patent Agents,* 322, *High Holborn, London, W C., to whom all inquiries should be addressed.*]

6,179. "Improvements in secondary batteries." O. Hamilton. Dated March 14th.

6,182. "A new medical electrical device." A. L. Burgess. Dated March 14th.

6,184. "Improved electric light for use as a search or signal light, for photographic and other purposes." E. M. Brown. Dated March 14th.

6,223. "Improvements in electric railways." C. M. White. (B. C. Seaton, United States.) Dated March 14th. (*Complete.*)

6,235. "Improvements in electrical insulators and method of making the same." J. W. Boch. Dated March 14th. (*Complete.*)

6,270. "Improved electrical lampholder." F. W. Heaton and H. Smith. Dated March 15th.

6,328. "A new and improved method of and apparatus for generating electricity." C. O'D. Barrows and C. H. Smith. Dated March 15th.

6,350. "Improvements in or connected with the manufacture of carbons for electric arc lamps." J. J. Waddington. Dated March 15th.

6,357. "Improvements in or in connection with electric motors for cars or other vehicles and in brakes therefor." W. P. Thompson. (T. von Zweigbergk, United States.) Dated March 15th. (*Complete.*)

6,360. "Improvements in or relating to electric light carbons." J. W. Strauss, J. G. Chapman, and H. Foster. Dated March 15th.

6,362. "Improvements in electric switches." T. Gillies and E. Hornidge. Dated March 15th.

6,371. "Improvements relating to the driving of sewing machines by electricity." H. Lea. Dated March 15th.

6,414. "Improvements in or relating to electric plug and ordinary switches." T. Topping. Dated March 16th.

6,451. "Improvements in apparatus for electroplating pins and other small objects." J. S. Morrison. Dated March 16th.

6,478. "Improvements in electrical connections for lamp-holders and other electrical appliances." R. F. Hall. Dated March 17th.

6,482. "Improvements in electric light advertising." E. Lightheart. Dated March 17th.

6,498. "An improved arrangement for forming or mounting the armatures of field magnets of small electro-motors." F. A. Darton and F. G. Phillips. Dated March 17th.

6,525. "Improvements in apparatus for electrolytic purposes." W. G. Luxton and The United Alkali Company, Ltd. Dated March 17th.

6,526. "Improvements in apparatus for electrolytic purposes." W. G. Luxton and The United Alkali Company, Ltd. Dated March 17th.

6,535. "Improvements in propelling barges and boats on canals and other water-ways by electricity." W. E. Kenway and T. V. Hughes. Dated March 17th.

6,559. "Improvements in electric arc lamps." G. C. Fricker. Dated March 17th.

6,605. "Improvements in telephonic inter-communication system." W. Aitken. Dated March 18th.

6,607. "A new or improved separator for the plates or electrodes of secondary batteries or accumulators." E. J. Clark. Dated March 18th.

6,619. "Improvements in microphones." L. M. Ericsson. Dated March 18th. (*Complete.*)

6,633. "An electrical charge conductor." F. W. Cooke and T. Ireland. Dated March 18th.

6,637. "Improvements relating to the electrolytic production of metallic alloys and to apparatus therefor." C. E. Acker. Dated March 18th. (*Complete.*)

6,649. "Improvements in dynamo-electric generators and motors." C. W. Atkinson and W. H. Johnson. Dated March 18th.

6,672. "An improved receiver for electro-magnetic waves." A. F. Eves. Dated March 19th.

6,695. "Improvements in electrical regulating apparatus." R. E. B. Crompton and S. W. Ashley. Dated March 19th.

6,704. "Improvements in switchboards for the control of high voltage electric circuits and apparatus." H. F. Parshall. Dated March 19th. (*Complete.*)

6,712. "Improvement in insulators." L. F. Rembe. Dated March 19th.

6,714. "Improvements in electric switches." E. M. French. Dated March 19th.

6,720. "Improvements in depressible rail systems for electrical railways." W. Grunow, Jun., and Z. Goodsell. Dated March 19th.

6,758. "Improvements in electric furnaces." A. M. G. Sebillot. Dated March 19th.

6,762. "Improvements in the means of and apparatus for transmitting pictures and the like by electric currents." W. E. Simpson. Dated March 19th.

ABSTRACTS OF PUBLISHED SPECIFICATIONS.

Copies of any of these Specifications may be obtained of Messrs. W. P. Thompson & Co., 322, High Holborn, W.C., *price, post free,* 9d. *(in stamps).*]

17,583. "Improvements for electric condensers." C. S. Bradley. Dated September 4th, 1897. This relates to electric condensers, the object being to increase the safety of the condenser, wider dielectric strain of the abnormal voltage, increase its life, to preserve a uniform capacity, and reduce its heating extent. To accomplish these aims, there is an electric condenser having its condensing plates and dielectric enclosed air-tight in a metallic casing, hermetically sealed at the joints to exclude the moisture of the air and preserve the condenser's capacity unaltered. The plates are held by stiff side-plates and are kept under pressure in an air-tight casing by a strong metallic frame, which projects beyond the edge of the casing and has a large heat radiating surface. 4 claims.

Cheques and Postal Orders (on Chief Office, London) to be made payable to Mr. H. ALABASTER, 4 Ludgate Hill E.C.

TRADING CORPORATIONS.

THE decision given by Judge Wightman Wood in the Leicestershire County Court a few days ago, in the case The Corporation of Leicester *v.* H. Warren Hill, is, we think, a very satisfactory one from all points of view. Our readers will, no doubt, remember that so long ago as 1895, we dealt with the question of local authorities trafficking in electrical goods, and to this and its cognate subject—the attempt on the part of such bodies to compete with wiring contractors—we have devoted attention from time to time since that date.

The judge in laying down what he believes to be the law on the subject, aptly remarked that this was a case of unusual importance to come before a court of limited jurisdiction. Although the action was ostensibly for the price of lamps and other fittings sold to the defendant, Mr. Warren Hill, the importance of the case lies in the motive that underlay the refusal to pay. Mr. Hill, in common with wiring contractors generally, feels very sore that his business should be injured by the powerful competition of local authorities, who, acting on the advice of certain officials, undertake to fit up premises and sell lamps and accessories as an adjunct to their public electricity supply. We imagine that so far as the sale, or giving away free, of incandescent lamps goes—or even the hiring out of arc lamps and motors—no one will make any serious objection to this action on the part of corporations or vestries, as obviously the consumers are likely to increase in number and importance if the undertakers adopt a truly progressive and energetic attitude in fostering their business and rendering as general as possible the use of electrical energy. The contractor benefits more than indirectly from such business-like pushing, because he has a greater number of potential clients, and it is his own fault if he does not get the orders for fitting up their premises and wiring to the apparatus which is let on hire.

When we come to wiring and installing, however, the aspect changes very materially. So long as the business of supply is assisted, it is to the interests of the wiring contractor to support the undertakers; but when those who hold statutory powers to supply not only do what they are fully entitled to do, but branch off into the domains preserved in most instances to the private individual, then we think that, morally, a wrong is done, and an act of injustice perpetrated for which there is very little excuse. The legal position may coincide with or differ from that dictated by elementary principles of fairness and justice, but it is hard to see how popularly elected bodies, whose revenue is derived from the inhabitants of a district generally, can explain their action without sophistry or an appeal to the principles which are of a class with those enjoyed by the members of Tammany Hall.

Coming back to the Leicester case, we find that the Corporation attempted to refute the argument that their dealing in fittings and installing was *ultra vires* by, firstly, quoting the Electric Lighting Act, which says the undertakers may "generally do all such acts and things as may be necessary and incidental" to electricity supply; secondly, by stating that the Board of Trade model form of accounts has an item, "By sales and repairs of lamps, arc or incandescent, or other apparatus." When it is remembered that it is customary in many towns for the Works, Highways, or Streets Department to take charge of and maintain the apparatus used for public lighting, *i.e.*, the standards, lamps, and street fittings above ground, it seems quite reasonable that provision should be made for any inter-departmental adjustment of accounts such as must occur if the electrical department purchases, erects, and then hands over the street lamps to another department or section of the local authority, after everything has been put in order and properly tested. It seems to us to be stretching the point to argue that because such a heading is provided, therefore one must assume that the purchase of the goods by outsiders and the general public is contemplated.

The first suggestion is very clearly dealt with in the judgment, "I am of opinion that the contention of the defendant that the Corporation acted beyond their legal powers in selling the articles named in the particulars is correct; and as to that part of the case, whether I am right or wrong, I have no difficulty in coming to a conclusion." To fully understand this it must be mentioned that the Corporation do not confine their sales of goods to consumers, but vend to the public at large, and yet we are told that selling lamps and fittings to private individuals who have no concern in, or connection with, the Corporation supply (except, of course, as ratepayers) is an act incidental to such supply!

The object of allowing the case to reach the County Court having been attained, there is not much technical interest in the actual judgment, although the legal aspect has its importance. "I am of opinion that the defendant having had the goods, cannot be allowed to refuse to pay for them on the ground that the Corporation went beyond their legal right in selling them, and could not be held to their contract to deliver them had they refused to do so. The defendant has got what he bargained for, and in my judgment he must pay the price, notwithstanding the flaw to which, I think, he has rightly called attention in the legal capacity of the Corporation to carry on their business." So we now know that the first Court holds the Corporation to be wrong in trading; but if people buy goods from the municipal shopkeepers, they must not expect to get off without leaving something in return therefor. And the Corporation had to pay the costs they incurred in bringing this action.

Much might be said about this case as typical of what is done, but we think it best to refrain from pressing home obvious truths. There is, however, a very interesting side light thrown on this matter by examining the action of Mr. Steinitz at West Ham. As a former Corporation engineer of Leicester, he knows the whole of the facts. We believe it is correct to say that his conviction is that Corporations make a mistake when they enter upon such work. We certainly draw the line between Corporations and companies, but how few of the latter have retained or done any good by a wiring department! The House-to-House Company at one time executed contracts, but found it best to leave alone what others could do better—better from the financial point of view—while the most noted success was the Liverpool company which not only did ordinary housework, but undertook the fitting up of the ss. *Teutonic* and *Majestic*.

The wiring contractor is the best friend the supply station engineer has from the business point of view (we have frequently said our say regarding their technical relations), and it is folly to expect that a municipal body can do work as cheaply as a contractor in these democratic days when trades unionism is rampant. Let "the cobbler stick to his last," and the corporation to its supply. Assuredly, the woes of the supply engineer are legion, without adding to them the pettifogging worry of customers' lamps burnt out, fuses blown, fittings damaged, &c. As a local authority neither needs nor benefits by making a profit on trading, it is only by some curious mental kink that the enticement of taking up installation work can be felt. One would think that the cleaner hands were kept of everything after the consumer's meter, the better, and the more time could be spent in and on the station and distribution. That this is the view of most of our municipalities is made evident by the careful way wiring is left alone, and the consumer plainly told that the undertakers do not supply light, but "units." The only other rational course is to go, not half-way, but the whole way, and wire every comer's premises, put in the lamps, and be responsible for the supply of light—as some even now would have us do.

When one sees the name of a Corporation appearing amongst a list of tenderers for a wiring job miles away from its own *locale*, it is high time that a definite ruling as to what may and may not be done under the Electric Lighting Acts should be given.

American Iron Manufacture.

THE July number of the *United States Consular Reports* contains a paper contrasting American methods of iron manufacture with English methods, the conclusion being that American competition is possible because of the huge size of the plants employed, the latest new furnaces at Duquesne belonging to the Carnegie Company having an output of 200,000 tons annually, or 40 times the average British output. There may be differences which enable American furnaces to be so much larger, but we imagine not sufficient to account for so very much as practice shows in the above. Similarly, there are several rolling mills capable of rolling 50,000 tons of rails per month, which is probably threefold the yearly production of any one mill in Great Britain. These differences enable the long hauls in America to be paid for. English railways, too, charge seven times as much as American railroads for carriage, so that there is but little advantage in the English short hauls. Successful men in America are more apt to use other people's capital than they are in England, where caution is more marked and old plant is apt to be continued in use too long. British caution has its advantages, of course, when bad times come, but caution may be overdone. We think a change is coming. The strike which has brought to the surface so vast an amount of information has had an educational influence we hope both on masters and men. Foreign competition has become appreciated, and before there is another strike most likely the men will learn that production and not restriction is the secret of success. There is ample margin for economy in English manufactures, in railway carriage, in mineral royalties and in more productive labour, while on the employers' side there must be no weakness in giving way to demands that are opposed to principles of economic science, and there must be a better recognition of education and ability. The sons of the wealthy must either be compulsorily dismissed from all control of works, or they must prove their fitness to control. The interference in shop management by the A.S.E. might possibly have been more strenuously resisted if brains had been better treated. For years English trade has been lashed round the miserable circle of laziness on the part of men and unscientific mastership by the sons of successful fathers. Men in command are often so ignorant of anything outside the run of news in a morning paper that they are unable to grasp the significance of a new process or a new machine. They succumb to the most gaseous traveller who can tell the most brazen fables, and they have no ears for the man who offers them a fortune, because they cannot discriminate between wheat and chaff. English trade wants purging at the source and at the sea. It is not all at the workman's end that the mischief is made. America has hardly had time to produce a second and third generation of the idle ignorant rich, and is not hampered in the same way.

SMALL ELECTRIC MOTORS.*

By JOHN DENNIS.

I see by your "Notes and Queries" columns that a great many readers are interested in small electric motors, such as you give instructions for the making of in your paper.

The greatest problem, however, seems to be the economical running of the same with a battery current.

It is time and money thrown away to attempt to use them continuously with a primary battery alone; but by using a storage battery, charging the same from gravity cells, we obtain good results.

As I have had a plant of this kind running almost continuously since January, 1894, my description of the same, giving the original cost and actual expenses per year, will perhaps be of interest to your readers who may wish to instal a similar one.

The plant consists of 12 6 × 8 gravity cells, placed in the cellar, connected in series, with two No. 14 insulated wires going through the outer cellar wall, then up to the attic, and through the storage battery, the distance being about 50 feet each way, which will make 100 feet of wire. The storage battery is of the chloride type, four cells connected in series, each cell composed of three plates, 7¾ × 7¾ inches, placed in a glass jar. To prevent accident, I enclosed the glass jars in a lead-lined box, using paraffined wood strips on the bottom, around and between the cells.

At first I had the connections inside the box, but soon found that they corroded with the splashing of the acid; so I soldered on rubber covered wires, then covered the joints with rubber cement and rubber strips, bringing them through the box and making all my connections on the outside. This works admirably. Another advantage of having them in a box this way is, that it prevents evaporation and it is not necessary to look at them for six months; then, if the acid is below the plates you can fill over them with a little water. Of course, there are the closed rubber storage cells which a person may get, but the cost is a good deal more. By having my storage battery in the attic in this manner, I am able to conduct my working wires to any room on the second floor, using No. 10 wire. If there was any apparatus on the first floor, wires could easily be carried from the charging wires in the cellar up through the floor to the same.

The principal part of the work is to run two sewing machines for family use, one of which is operated by the "Simple Electric Motor," with a cast field and segmental commutator on the shaft. This is inclosed in a box or cabinet on casters, and stands at the right-hand side of machine, the shaft being long enough to come through one side and the end of same running in a small hole bored in the iron frame of the sewing machine, between which and the box is a small pulley on the shaft, with a belt running to the pulley of machine. There is a switch placed on the wall to cut off the current when not in use; also a foot switch placed on the treadle and made out of an ordinary window burglar alarm. This leaves both hands free to work with. Three resistance coils, consisting of No. 18 iron wire coiled on brass rods covered with asbestos, are placed inside the motor box, underneath the cover, and connect with a three-point switch on top of the box. When connection is made by the foot, and the switch is not on any of the points, the motor is running in series; and if the storage battery is highly charged, or if the work is light, it will be very satisfactory. Should the work be heavy, however, or the battery low, by switching on the points we allow more current to go through the armature, thereby getting more power.

I have made the "Simple Motor," the "Parkhurst," and the "Hand Dynamo," but the best one seems to be the "Simple Motor," that is, it seems to have more power for the amount of current passing through.

In another room I have the "Parkhurst" motor running a Singer sewing machine, connected somewhat similarly; only instead of the motor being in a box, it stands on the table of sewing machine, the resistance being in the base.

I have also a fan which I use occasionally in the hot weather, two small incandescent lamps of 4 candle-power, and an alarm clock which rings a bell and lights a lamp at the same time.

I have had no trouble whatever with the storage battery since first starting. The gravity cells I test about once a month. If they are above 25° Baumé, I take out three glasses of zinc sulphate from each cell, add more blue vitriol if necessary, clean off the zincs and fill up with soft water.

I have a simple galvanometer in the circuit which I can switch on or off, and from the amount of deflection of the needle can readily tell whether they are charging all right or not. One can cast his own zincs by making a pattern and casting in common fine sand, saving about one-half the cost.

If there are two parties living in one house, one can easily rent out power to the other for, say, 50 cents per month, or he could run wires across a short distance to his neighbour. I think the plant would furnish enough current for three family sewing machines; that is, to charge continuously, always having the gravity cells connected up. Below I give approximate cost per year for this way. At present I let mine charge till they use up 25 lbs. of blue vitriol, then I disconnect them from storage battery, take out the zincs, clean and dry them, and let them stand till storage battery gets low, then charge up again.

First cost, 4 storage cells at $5 25 each	$21.00
" " 12 gravity cells without zinc	4.20
" " wire, &c.	5.00
